Let us now consider the somewhat more economical case of an engine in which the steam is first used as described above, but afterwards, instead of being allowed to pass into the atmosphere, is conducted through a pipe into a closed vessel, and there condensed. The process commonly called condensation, and associated with the idea of liquefaction, consists in essence merely of the subtraction from steam of a portion of its sensible heat. This reduction of temperature has a double effect on the steam—first, the liquefaction of a part of it; and then, the reduction of the rest to the pressure corresponding to the reduced temperature. (It will be remembered that steam exists at *all* temperatures.) It is not possible to do one of these things without the other, and this fact lies at the bottom of a correct conception of what is called by engineers a 'vacuum.'

What is commonly called 'vacuum' simply means pressure less than the atmospheric pressure; and, in the case of steam-engines, a vacuum generally implies a pressure of between two and four pounds per square inch—that is, from a seventh to a fourth of the ordinary pressure of the air. The most common way of condensing steam is by bringing it into contact either with a jet of cold water, or with surfaces kept continually cool by a current of water. In either case, directly the steam is brought into contact with the water, or cooling surfaces, it transfers to it the larger portion of its sensible heat. During this process, the greater part of the steam is liquefied, and the remainder retains only such a pressure as corresponds to its greatly reduced temperature.

The advantages possessed by a condensing over a non-condensing engine will now be obvious. When the piston is being forced from C to D by steam entering through C, the force on the back of the piston resisting its motion in that direction, instead of being equal to the pressure of the atmosphere, is only the pressure of the steam in the condenser, or about 1 pound per square inch. The net effective force is therefore 60—1, or 59 pounds, instead of 60—15, or 45 pounds. In actual practice, these figures would be modified, because, from various causes, such a low back-pressure as 1 or 15 pounds above zero (in condensing and non-condensing engines respectively) is never obtained, but the principle remains the same.

We have supposed that our cylinder, when full of steam, contained just 1 pound-weight at 60 pounds pressure. Let us now find out how much useful work this pound of steam has done for us, and we will then show how the same weight may be made to do a great deal more, by utilizing more of its great store of heat. Let us suppose that the area of the cylinder is 2 square feet, while its length (the stroke of the piston) is 3½ feet. It will thus have a capacity of 7 cubic feet, as before assumed. In the first case described, we should have a pressure of 45 pounds per square inch exerted on an area of 288 square inches through a distance of 3½ feet. This is equal to 45,360 foot-pounds of work. In the second case, we have a pressure of 59 pounds per square inch on the same area, and through the same distance. This is equal to 59,472 foot-pounds of work, or about $\frac{1}{13}$th of the total heat supplied by the fuel.* We may now proceed to examine the way in which the same weight of steam, generated by the consumption of an identical weight of fuel, may be made to perform many times more work by 'working expansively.'

One of the properties possessed by steam, in common with all other gases, is a tendency to expand indefinitely. In article STEAM we mentioned and illustrated the fact that its pressure varied nearly inversely as its volume. For simplicity's sake we shall here assume that steam is a perfect gas, and follows Boyle's law, the pressure varying *exactly* inversely as the volume. We shall now describe the way in which this expansibility of steam is taken advantage of by the engineer. If we have a cylinder of the same area as before, but of twice the length, but only intended to admit one pound of steam into it at a time, it will be necessary, when the piston has traveled 3½ feet of its stroke, to shut the entrance valve, so as to prevent more steam entering; this is called 'cutting off' the steam.

The piston, however, still continues its motion in the same direction as before, propelled by the internal separative energy among the particles of steam. But as it is pressed forward, the space occupied by the steam is always increasing, and its pressure always decreasing in proportion, until at length, when the piston has reached the end of its stroke, the steam occupies exactly double its original volume—namely, 14 cubic feet, and is reduced in pressure to half its original pressure—namely, to 30 pounds per square inch. We have thus during the first half of the stroke a constant pressure on the piston of 60 pounds per square inch, and during the second half a pressure gradually decreasing from 60 to 30 pounds. The *mean* pressure during this second half of the stroke will be found on calculation to be almost exactly 40 pounds. Let us now, in the same way as before, see what work we have been able to get out of our pound of steam by expanding it in this way. In the first half of the stroke we have 59,472 foot-pounds of work exactly as before, and then we have in addition a mean pressure of 40—1, or 39 pounds per square inch, exerted over 288 square inches for a distance of 3½ feet. This equals 39,312 foot-pounds, making a total of 98,784 foot-pounds of work obtained from the steam which only gave us 59,472 before. The economy of working expansively, however, goes much further than this. If the cylinder had been four times its original length, and the steam had been cut off at the same point as before (which would then be quarter instead of half stroke), we should have obtained from the 1 pound of steam 144,345 foot-pounds of work. If we had gone still further, and expanded the pound of steam into eight times its original volume, we should have obtained no less than 179,984 foot-pounds of work, which is more than three times as much as at first.* All modern engines are worked more or less on this principle of expansion, and the general tendency seems to be every year to adopt higher initial pressures, and larger ratios of expansion.

Having thus briefly sketched the history of the steam-engine, and the theory of its action, we may now proceed to some consideration of its mechanism. Fig. 3 represents Watt's 'double-

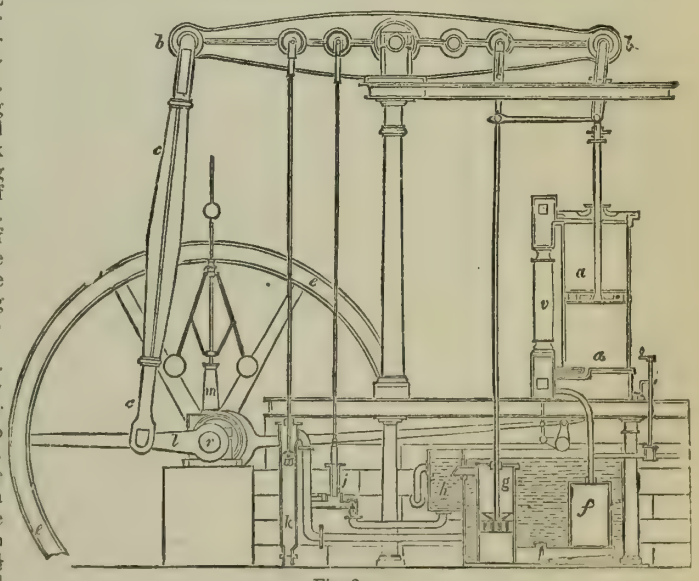

Fig. 3.

acting' condensing engine, which we have already mentioned. By 'double-acting engine' we mean an engine such as was sketched in fig. 2, in which the steam acts on both sides of the piston instead of only on one, as in Newcomen's engine. Watt's engine, though not of the form now generally used, contains all the parts now considered essential; and we may therefore describe it before saying anything about these parts in detail. The steam from the boiler passes direct to the valve-chest *v*, which is simply a long box attached to the cylinder *a*. In this chest are placed valves, which are so regulated as to open communication between the boiler, cylinder and condenser, in such a way that when the top of the cylinder is open to the boiler, the bottom communicates with the condenser, and *vice versâ*. When the steam has done its work, it passes out through the bent pipe into the condenser *f*, where it is met by a jet of water (not shown in the engraving), and

* For simplicity's sake, we have here assumed that the water in the boiler has to be raised from 32° to 292°, and evaporated at that temperature. If the water were supplied at 212°, then the work done would be about one-thirteenth instead of one-fifteenth of the total heat.

* In actual working, owing to various causes—such as imperfect action of the valves, radiation from the cylinder, bad vacuum &c.—the work obtained from the steam is not more than ·65 to ·75 of that given in this paragraph.

condensed as before explained. *g* is a pump called the air-pump, which continually draws away the contents of the condenser, and discharges them into a cistern *h*, called the hot-well. A small force-pump *j*, draws part of the water from this cistern, and sends it back again to the boiler, there to be reconverted into steam, while the rest of the water is allowed to run to waste. A suction-pump *k*, supplies water to the large tank round the condenser, and also for the condensing jet. Inside the cylinder are the piston and the rod (called the piston-rod) connecting it with the beam *bb*.

In Newcomen's engine, the rod had only to pull the beam down, and not to push it up; it could, therefore, be connected to it by a chain, as shown in fig. 1. In the double-acting engine, the piston-rod is required both to pull and to push the beam, so that the chain is no longer admissible. It is obvious that as the head of the rod must move in a straight line, while every point in the beam describes an arc of a circle, the two cannot be rigidly connected. Watt invented the arrangement of rods shown in fig. 3, by which the piston-rod head is always guided in a straight line, while the end of the beam is left free to pursue its own course. This is called a 'parallel motion.' The end of the beam furthest from the cylinder is connected by a rod *cc*, called a connecting-rod, to the crank *l*, which is firmly fixed on the shaft; and by this means the reciprocating motion of the beam is converted into the rotary motion of the 'crank-shaft' *r*. The governor *m*, and the fly-wheel *ee*, will be explained further on.

The *cylinder* and its *piston* are both made of cast-iron. The former is very accurately bored in a lathe, and ought always to be covered outside with non-conducting-material to prevent radiation of heat. It is frequently enclosed in another cylinder, and the annular space, or 'jacket' between them filled with steam from the boiler, principally with the object of preventing liquefaction in the cylinder, which is fatal to economical working. The openings for the entrance or discharge of the steam (*c* and *d* in fig 2) are called *ports*.

The *valve* or valves which regulate the admission of steam to the cylinder vary very much in construction and design. In ordinary engines one valve, called a *slide-valve*, does the whole work for each cylinder in a way which we shall explain by the aid of fig. 4. This figure shows the valve in two positions—namely, those corresponding to the times when the piston is at the middle of its stroke, going in the two different directions—*c* and *d* are the ports, the ends of which are denoted by the same letters in fig. 2; *b* is the 'exhaust port,' or opening through which the steam passes to the condenser; and *a* is the slide-valve working inside the steam chest (not shown). The sketch to the left shows the position of the valve when the piston is moving upwards. The steam enters the cylinder through *d*, as shown by the arrows, while the steam in the other end is free to rush out by *c*, under the valve, and through *b* into the condenser. By the time the piston has reached the same position, going in the opposite direction, the valve is in the position shown in the right-hand sketch, and the motion of the steam is exactly reversed. When it is desired to 'cut off' the steam earlier than half-stroke, a separate valve, called an *expansion valve* (of which there are innumerable varieties) is generally used. The rod to which the piston is attached is called the *piston-rod*, and the rod which actually drives the crank the *connecting-rod*. In Watt's engine, and similar machines, these are connected to opposite ends of a *beam*, but in the common type of engine shown in fig. 6 (below) the two rods are directly attached.

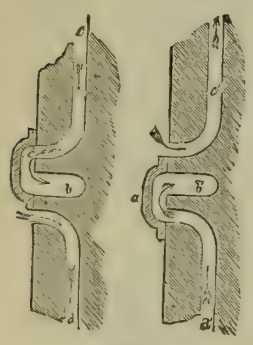

Fig. 4.

The *fly-wheel* is a large wheel fixed on the crank shaft, and having a very heavy rim. As it revolves, this contains, *stored up* in itself, a great quantity of energy, and so equalizes the motion of the shaft, and, by *restoring* some of the energy, enables the engine to pass the 'dead-points,' or points at which the connecting-rod and crank are in a line.

The *condenser* is simply a cast-iron box of any convenient shape. The water for condensing the steam is introduced into it in a jet in such a way that its particles mix with the steam at once on entering, and condense it almost instantaneously.

The *governor*, shown in fig. 5, is an ingenious application by Watt of mechanism long used in water-mills. Its object is to make the engine to a great extent regulate its own speed, so that it shall neither be pulled up altogether by a sudden increase of load, nor 'race' when any part of its load is suddenly removed. It consists essentially of a spindle or upright rod, with a pulley, by which it is caused to revolve, fixed on it. Two levers are pivoted on a pin near the top of the spindle, and at the lower end of each is fixed a heavy cast-iron ball. When the engine is running at its proper speed, the balls revolve with the spindle in the position shown; but if that speed be increased, the centrifugal force causes them to fly outward, and consequently upward; and conversely, if it be decreased, they fall downward towards the center. At the upper end of the spindle is a system of levers, by which it will be seen that the raising of the balls tends to close, and their lowering to open, the *throttle-valve* at the right of the engraving. This valve is simply a disc of metal placed in the steam-pipe near the cylinder. The further, therefore, it is opened, the greater the amount of steam admitted to the cylinder, and *vice versâ*, and so the tendency of the engine to alter its speed arising from causes extraneous to itself, is just balanced by the alteration made in the amount of steam admitted through the throttle-valve. In order that economy as well as regularity of working may be attained, the governor should, however, be so arranged as to control the 'cut-off' instead of throttling the steam as in the figure.

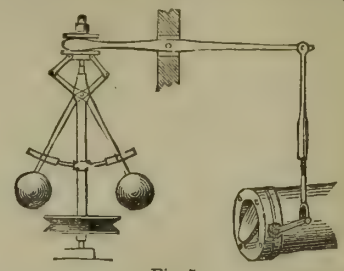

Fig. 5.

The 'Cornish' engine, so called from the fact that it is principally used in the Cornish mines, resembles Watt's engine in general appearance. Like Newcomen's engine, it is used exclusively for pumping, and has no rotary motion, and it is virtually single-acting; but unlike his, the steam pressure, and not that of the atmosphere, actually does the work. It is not easy to say why Cornish engines have remained so long in their original form. They are economical of fuel, owing to the great expansion used, but the same expansion could also be used with many other forms of engine. They are very costly, and extremely heavy and unwieldy, and it seems probable that it is only prejudice which stands in the way of their being superseded by small engines running at high speeds, which would do the same work as economically, and with a much smaller outlay in first cost.

Engines in which the piston-rod and connecting-rod are directly attached are called *direct-acting engines*, of which the horizontal engine, shown in fig. 6, is the most common type, and for all ordinary purposes is rapidly superseding every other form of stationary engine. It possesses the merits of having great simplicity and few working parts, and of all these parts being easily accessible to the engine-driver; and at the same time any required degree of economical working can be obtained in it as well as in any other form. It was for a long time only used as an non-condensing (or so-called 'high-pressure') engine, but is now frequently made with a condenser attached.

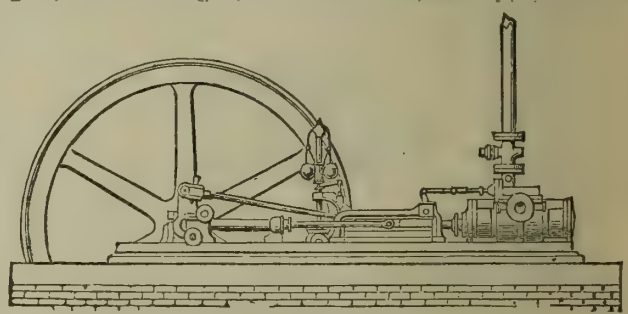

Fig. 6.

Two other forms of direct-acting engines have been much used in their day, but are now being rapidly abandoned except under special circumstances; these are called respectively the 'oscillating' and the 'trunk' engine. In the former (which has rarely been used except for marine engines) the crank-shaft is above the cylinder, the piston-rod head is attached to the crank-pin, and the connecting-rod is dispensed with by allowing the cylinder to oscillate on large hollow centers called *trunnions*, and so to adapt itself to the various positions of the crank-pin. In the 'trunk' engine, the piston-rod becomes a hollow cylinder or *trunk*, large enough to allow the connecting-rod to vibrate inside it. The latter is then attached at one end to the crank-pin as usual, and at the other to a pin fixed in the piston.

An immense amount of ingenuity has been expended in devising engines in which the rotary motion of the shaft is obtained *directly* from the piston without the intervention of reciprocating

parts. These machines are called *rotary* engines; they have never come into general use, and most of them have been defective in construction, as well as founded on a dynamical misconception.

In *locomotive engines*, it is necessary that the whole machinery should be compressed into the smallest possible bulk, and this necessity is the cause of their principal peculiarities. The engine itself is much the same as an ordinary horizontal engine, and has two cylinders placed side by side near the front of the locomotive. These cylinders are sometimes placed inside the main framing, which runs the whole length of the engine, and sometimes outside it, each plan having certain advantages. Fig. 7 is an

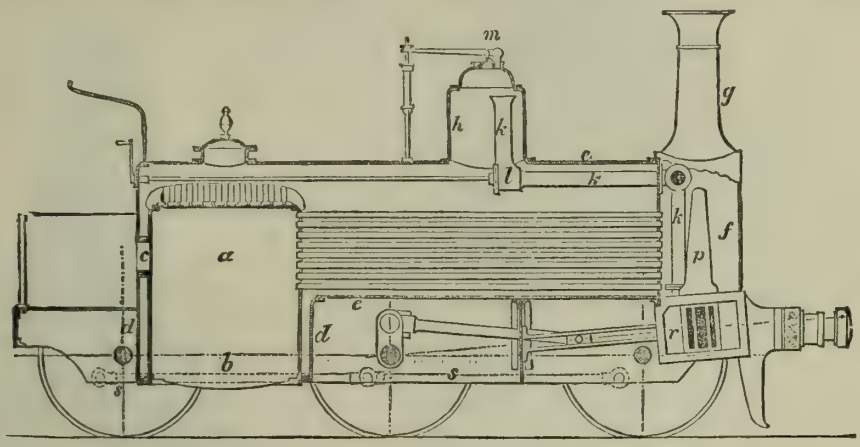

Fig. 7.

outline section of an 'inside cylinder' goods locomotive belonging to the Midland Railway Company. At the back of the locomotive is the fire-box *a*, the bottom of which is formed by the grate *b*. Fuel is introduced by the door *c*. The fire-box is enclosed in a casing *d*, and the space between is filled with water. This space communicates freely with the barrel *e e* of the boiler, a long wrought-iron cylinder. From the back of the fire-box numerous small tubes traverse the boiler (through the water) to the smoke-box *f*, and conduct the products of combustion to the chimney *g*. The steam-pipe *k* is led away from near the top of the dome *h*, and fitted with a regulator valve *l*. At *m* are a pair of spring safety-valves. Both cylinders discharge their steam through the vertical blast pipe *p*, and by this means a sufficient draught is caused, notwithstanding the small height of the chimney. The cylinders *r* are placed in the bottom of the smoke-box, and partly enclosed in it.

In all *marine engines*, except the very smallest, two cylinders are used, working cranks at right angles to each other, so as to equalize the motion as far as possible, it being almost impossible to use a fly-wheel of sufficient weight for that purpose on board ship. In vessels of war, where it is essential that all the machinery should be kept below the water-line, horizontal engines are used, often of the 'trunk' type. In merchant vessels, however, and in all cases where there is no necessity for the machinery being kept low down in the ship, the form known as the 'steam-hammer' engine, or some modification of it, is now almost universally adopted. These engines derive their name from their resemblance (in their earlier designs) to Mr. Nasmyth's steam-hammer, the form of which seems to have suggested their arrangement. They are direct acting, but the cylinders are inverted, and placed right above the propeller shaft.

The two greatest improvements in the modern steam-engine—the *surface condenser* and the *compound engine*—have been brought to perfection chiefly in connection with marine engines, and we may therefore mention them here. In the surface condenser, the steam is condensed by contact with the surface of a great number of small tubes, through which a current of cold sea water is kept constantly flowing. By this means the condensing water and the condensed are kept separate, the former being returned to the sea, and the latter only sent into the hot-well. The boiler, therefore, is continually fed with distilled water, and the wasteful process of 'blowing-off,' to get rid of the unvaporizable matter which would otherwise be deposited in the boiler, is rendered unnecessary.

In 'compound' engines, the two cylinders are of unequal size—the larger, called the low-pressure cylinder, having from three to four times the capacity of the smaller or high-pressure cylinder. The steam from the boiler is admitted into the latter in the usual way, and cut off generally at from ⅓ to ½ of the stroke; and after doing its work there, it is conducted to the large cylinder, where its reduced pressure, by acting on an increased area, does as much work as in the other cylinder, and thence to the condenser. This system of engine has several notable advantages—among which are that the internal stresses are more uniform than in ordinary engines; that leakage past the piston becomes of less importance; and that for any given *large* measure of expansion, the mechanism of the engine is much more simple and less liable to get out of order than for the same degree of expansion carried out independently in two cylinders.

The Work done by Steam-engines.—This is estimated in two ways—as *horse-power*, and as *duty*, and the first expression includes two things—nominal and indicated horse-power. Thirty-three thousand foot-pounds of work done per minute is called one horse-power, this being considered by Watt as the maximum force which a strong horse could exert. The *nominal* horse-power of an engine has long ceased to be any expression of the actual power it exerts; it is only used as a kind of commercial standard (a very deficient one) for the sale and purchase of engines, and is generally made to depend entirely on the diameter of the cylinder.

The indicated horse-power is the most useful measure we have of the work done by an engine. It expresses, however, the total work done by the steam on the piston, and does not show at all what proportion of that work has to be expended in overcoming the friction of the engine itself. It is ascertained by the use of a little machine called an 'indicator,' devised by Watt, and since his time greatly improved, especially by Mr. Richards.

By taking the *mean* pressure per square inch on the piston throughout the stroke (deduced from the indicator card), and multiplying it by the area of the piston, and by the number of feet passed through by it in a minute, we should find the number of foot-pounds of work done by the engine per minute; and this, divided by 33,000, would give the indicated horse-power.

'Duty' is a measure of power used only for pumping-engines, and differs from horse-power in being entirely independent of time. It is the number of foot-pounds of nett work resulting from the consumption of a given quantity of coal, usually either a bushel of 94 lbs. or a hundredweight. At the beginning of this century, the maximum duty that had been attained by any Cornish engine was 20 millions of foot-pounds per cwt. of coal, but six times that duty has since been occasionally obtained. In these engines, it is the actual nett work done which is taken into account; the duty would be 20 or 25 per cent. greater if the total load on the steam-piston had been considered instead.

For engines whose power can only be measured by the indicator, the standard of economy is the number of pounds of fuel used per hour per indicated horse-power. In factories where 'dross' is used as fuel, with horizontal engines and Cornish boilers, and where no means are taken to insure economy, we have known 15 to 20 pounds of fuel burned per indicated horse-power per hour. In marine engines and other cases where the best coal only is used, and where high pressures, surface condensation, and compound cylinders are employed, the consumption of fuel is often as low as 2 pounds.

The theory of a 'perfect heat-engine,' which should return in mechanical work (see FORCE) the greatest possible amount of the heat supplied to it, is considered under THERMODYNAMICS. For other points, see articles BOILER, SAFETY VALVE, and SCREW PROPELLER, as well as STEAM; and STEAM-ENGINE and MARITIME CONVEYANCE in *Information for the People*. See also, for theory, Rankine's *Steam-Engine* and Cotterill's *Notes on the Theory of the Steam-Engine;* for history, Galloway's *The Steam-Engine and its Inventors* (1881).

STEAM-HAMMER, THE, has doubtlessly contributed more than any other mechanical invention of modern times in developing the

wonderful resources of the iron trade. The first idea of a steam-hammer appears to belong to James Watt, the great father of engineers, and was patented by him in 1784. In 1806, a William Deverell, described as 'an engineer of Surrey,' also took out a patent for a steam-hammer; but in neither case does it appear that steam-hammers were actually constructed, though in both specifications a direct acting steam-hammer is, so to speak, sketched in words. From this time till 1839, the idea seems to have been entirely lost sight of, when it was again taken up by Mr. James Nasmyth, of the Bridgewater Foundry, near Manchester, as the result of an application made to him by Mr. Humphreys, engineer to the Great Western Steamship Co., who had been unable to induce any forge-master to undertake the forgings required for the paddle-shafts of the *Great Britain* steam-ship, then in course of construction. Mr. Nasmyth sent a sketch of his hammer plan to Mr. Humphreys, who, along with Mr. Brunel and others, heartily approved of the scheme, but in consequence of an alteration in the arrangements, the paddle-shaft was not required, and the hammer was not then constructed. The scheme was offered to many of the large forge-masters and engineers; but they failed to duly appreciate its value and importance, and the hammer remained a mere sketch in Mr. Nasmyth's 'scheme-book' till 1842. In the spring of that year Mr. Nasmyth, much to his surprise, saw at Creuzot in France a steam-hammer which had been made from a copy of his own rough sketch, and in the following June he secured a patent for it in England.

The first English steam-hammer, in accordance with his plan, was made at the Bridgewater Foundry early in 1843; but although considered as an improvement upon the old 'helves' hitherto used for forging purposes, it was far from being a perfect tool. See fig. 1. The hammer was worked by means of an

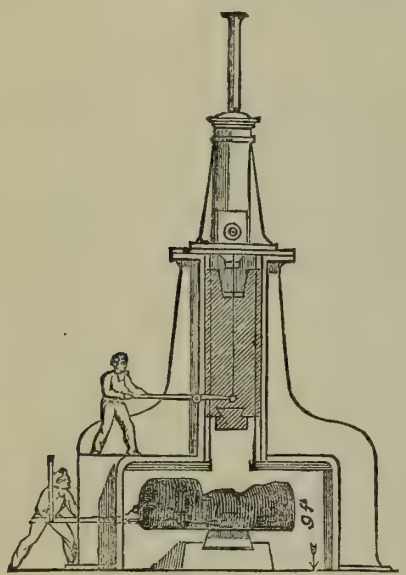

Fig. 1.

ordinary slide-valve and a long lever, requiring great labor and constant attention in order to give the blow required; thus some other contrivance was necessary, to secure complete command over the power of the blow, and in order that, the instant the blow was struck, the block should immediately rise again, so that the heat in the mass of iron on the anvil might not be reduced by the cold face of the block. The peculiar difficulty of securing a true automatic arrangement will be seen when it is considered that the instant of percussion must vary with almost every blow that is struck; for the piece on the anvil becomes thinner and thinner by each succeeding blow, and in flat bars, a blow is first given on the flat side, and then on the edge, the difference in the fall of the hammer in the two cases being oftentimes several inches; and further, that the hammer must be under perfect control at all times.

Mr. Nasmyth, after many and protracted trials, failed to produce the motion required, and, as a consequence, the whole hammer scheme was on the point of being abandoned. In this dilemma, and during Mr. Nasmyth's absence from the works, his partner, Mr. Gaskell, applied to their engineering manager, Mr. Robert Wilson, who afterwards became managing partner and successor to Mr. Nasmyth, to endeavor to solve the problem which had hitherto baffled the skill of Mr. Nasmyth. Mr. Wilson took the matter in hand, and in little more than a week, a motion was invented and attached to a hammer upon which former experiments had been made, and was at once found to answer most admirably every condition required. Under the influence of this very beautiful mechanical motion every variety of blow could be given, from the gentlest tap to the heaviest blow within the compass of the hammer, and that, too, perfectly self-acting in every respect, the long lever and the hard work before referred to being now entirely banished. By simply altering the position of the tappet lever by means of two screws, a blow of the exact force required could be produced and continued so long as steam was supplied. So completely was the hammer now under control, that it became a favorite amusement to place a wine-glass containing an egg upon the anvil, and let the block descend upon it with its quick motion; and so nice was its adjustment, and so delicate its mechanism, that the great block, weighing perhaps several tons, could be heard playing tap, tap, upon the egg without even cracking the shell, when, at a signal to the man in charge, down would come the great mass, and the egg and glass would be apparently, as Walter Savage Landor has it, 'blasted into space.'

On the 18th August 1843, the first hammer made like fig. 2 was

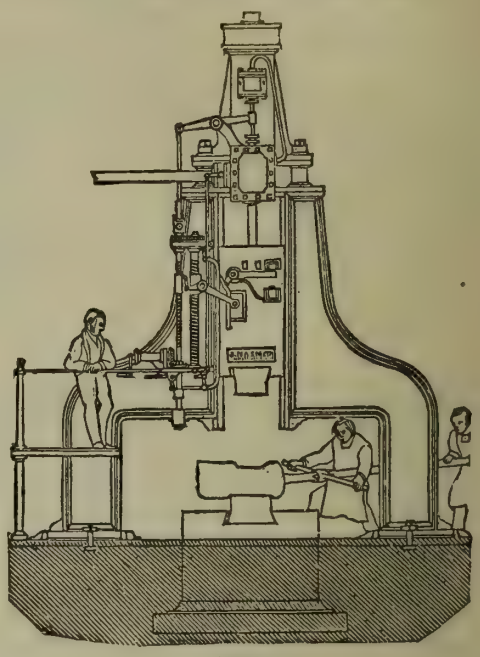

Fig. 2.

delivered to Messrs. Hird, Dawson, and Hardy of the Low Moor Iron-works, near Bradford, Yorkshire, and gave such satisfaction, that orders for this remarkable tool began to flow in from all parts of the country. The hammer remained in this condition, with the exception of a few minor details, from 1843 to 1853, when Mr. Wilson (who in the interim had removed to the Low Moor Iron-works) invented, patented, and applied to the hammers at Low Moor and elsewhere what is called the 'circular balanced valve.' The *Practical Mechanic's Journal* for 1855, vol. viii., p. 174, in an article on this invention, says: 'The wonders of Mr. Nasmyth's invention, the steam-hammer, have just received new lustre at the hands of Mr. Wilson, to whom belongs a large portion of the credit attaching to the early practical development of the beautiful automatic action of this invaluable tool. The special feature which Mr. Wilson has introduced is his balanced-pressure cylindrical valve, several modifications of which we noticed in our pages of June and July last year. Hammers divested of all self-acting apparatus whatever, and fitted merely with a hand-geared valve of this kind, exhibit an immensely improved action, enabling the workman to obtain the exact kind of blow he wants under all circumstances.

In July 1856, Mr. Wilson returned to the Bridgewater Foundry as managing partner in the firm of James Nasmyth and Company, and in September following obtained a patent for a *balanced slide-valve*, and at once arranged to apply his invention, which arrangement continues in operation to the present time. His balanced side-valve, by a most ingenious arrangement, allows the valve, as it were, to float in an atmosphere of steam pressing equally upon it on every side, entirely doing away with all superincumbent pressure upon the *valve*, no matter what the pressure in the *boiler* may be. Hammers are now made of such a size, that, if the valve were not balanced, a small steam-engine would be required to move it.

In June 1861, Mr. Wilson patented and introduced another very important improvement, popularly known as the *double-acting hand-gear motion*. By this arrangement, the steam is admitted as before to *raise* the piston, and when it has attained the required elevation, and at the very moment when about to descend, by

slightly increasing the travel of the hand-lever (more than when working single-acting), the steam is admitted into the cylinder *above* the piston, which accelerates and increases the intensity of the falling blow and the consequent capacity of the hammer; so much so, that that which had hitherto been described as a 5-*ton* hammer is by this double-action arrangement increased to at least a 12½ or 15 ton one.

In 1862, Mr. Wilson designed and constructed a small hammer suitable for tilting steel, fitted with the balance-valve, double acting, and with an entirely new self-acting motion (much less complicated than the original one), capable of striking *five hundred* blows per minute.

Fig. 3 shows the form of the more modern and simplified steam-

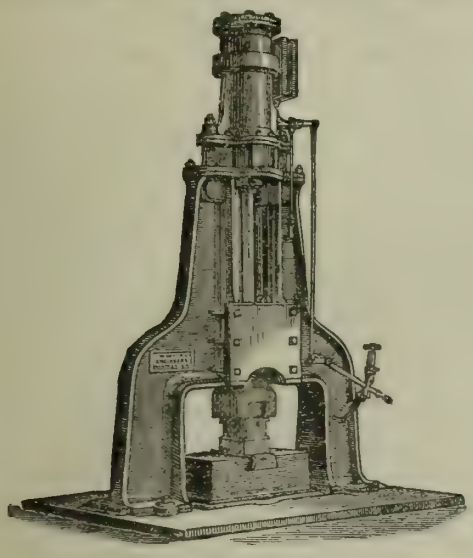

Fig. 3.

hammer. Several 50-ton hammers, made double-acting in the way above-mentioned, so as to be equal to a 100-ton single-acting one, are in operation in large iron-works.

In the Nasmyth hammer, the steam cylinder is fixed, and the large hammer head is attached to a comparatively small piston-rod. But in another type of hammer (Rigby's patent), which has been made in large numbers, the piston-rod itself, with only a slight enlargement at the striking end, forms the actual hammer. This form requires no 'guides' below a short casing under the steam cylinder and as it is chiefly used for small hammers, supported by a single standard, it gives plenty of room for workmen to forge with it. Condie's steam-hammer—perhaps the earliest modification of Nasmyth's—is so planned that the steam cylinder itself moves, and with the simple addition of a face piece, forms the hammer. This form seems to have fallen greatly out of use. Of late years, duplex steam-hammers have been used. In these there is no anvil, but two opposing horizontal hammer heads deliver blows of equal force on opposite sides of the forging.

STEAM-NAVIGATION. When once steam was known as a moving power, its application to navigation was obvious enough; it was even to this purpose that the first attempt was made to apply it at all—that of Blasco de Garay—namely, in the harbor of Barcelona in 1543. See STEAM-ENGINE. The only surprising thing is, that thirty years should have elapsed—between 1777, when the steam-engine had become in Watt's hands an efficient power for other purposes, and 1807, the date of Fulton's first voyage—before a really serviceable steam-vessel was produced. The connecting link seems to be the use of revolving-paddles instead of oars. Wheel-boats propelled by oxen, horses, or men were known to the Romans, and were used for ferry-boats in modern times. Some experiments with this mode of propulsion made by Mr. Miller of Edinburgh, suggested to his friend Mr. Taylor the application of steam as the moving power, and led to the most decided step in the discovery of steam-navigation previous to the final success of Fulton.

As early as 1736, Jonathan Hulls had taken out a patent for a tow-boat to be propelled by a paddle-wheel set in motion by a sort of steam-engine. The project appears never to have been executed. Besides some experiments on the Seine by Comte d'Auxiron in 1774, and Perier in 1775, the Marquis de Jouffroy constructed a steamboat of considerable size in 1782, which navigated the Saône for some time; it was deficient, however, in power. In America experiments began to be made about 1783, by Fitch and Rumsey. Fitch launched a paddle steamboat in 1788, which moved at the rate of four miles an hour; but before proceeding far the boiler burst. Rumsey proposed to propel the vessel by making a stream of water issue with force from the stern; his attempt failed.

The next important experiment was the one above alluded to, by Messrs. Miller and Taylor. It took place on a small lake on Mr. Miller's estate of Dalswinton in Dumfriesshire. A small engine having four-inch cylinders of brass was prepared, under the superintendence of Mr. Taylor, tutor in Mr. Miller's family, and Mr. Symington, an ingenious mechanic, and fitted on board a double-boat, with a paddle-wheel in the interspace. The trial took place amid a concourse of hundreds on October 14, 1788, and with perfect success. Next year Mr. Miller had larger engines fitted into a vessel, and tried on the Forth and Clyde Canal, when the vessel moved at the rate of seven miles an hour. Partly from caprice, partly from derangement of his affairs, Mr. Miller was diverted from pursuing the matter farther. But in 1801, Mr. Symington took out a patent for the construction of steamboats, and in 1803 built the *Charlotte Dundas*, to tow vessels on the Forth and Clyde Canal. The success seems to have been complete, excepting in one respect, that the agitation of the water by the paddles was found to wash down the banks in an alarming manner. The use of the vessel was therefore given up, and it lay at *Lock Sixteen* for many years.

In the meantime, attempts had been making at steam-navigation in America by Stevens, Livingston, and others. Robert Fulton, another American, had thought of steam as a motive-power for vessels, as early as 1793. Traveling into Scotland he visited the unfortunate *Charlotte Dundas*, and obtained drawings of the machinery. Returning to America with one of Boulton and Watt's engines of 20 horse-power, he, in conjunction with Livingston, built a vessel called the *Clermont*, at New York, and in 1807 made the first really successful voyage by steam from New York to Albany, up the Hudson. The vessel sailed 110 miles in 24 hours, against stream and wind. Fulton has thus indisputably the honor of having first proved the practical utility of steam-navigation. Yet nothing but perseverance seems to have been wanting to crown the experiments of Miller, Taylor, and Symington with equal success. Four years later, 1811, Henry Bell of Glasgow, who had witnessed the experiments on the Canal in 1789, and had accompanied Fulton on his visit to the *Charlotte Dundas*, started a steamboat, the *Comet*, on the Clyde, and was thus the father of steam-navigation in Britain.

In 1815, a steamboat made a passage from Glasgow to London, and in 1818, one plied from New York to New Orleans; it was not till 1820 that steam-packets were established between Holyhead and Dublin. 1838 was a memorable year in the history of steam-navigation. The steamer *Sirius* sailed from Cork on the 4th of April, the *Great Western* from Bristol on the 8th of the same month; both arrived at New York on the 23d, the *Sirius* being only twelve or fifteen hours before the other. The passage is now often made from Queenstown to New York in six or seven days. The opening of the Suez Canal greatly promoted swift steam-communication with India, China, and the East, and Australia. Since 1880, some of the Orient line of steamers do the passage from Plymouth to Australia in from 30 to 35 steaming days. Steam-vessels are now to be found on all seas and lakes and navigable streams. War-steamers have taken the place of the old ships of the line; and except for the transport of heavy goods to long distances, steam bids fair to supersede the use of sails. The maximum speed yet attained by steam-vessels is 20 miles an hour; the ordinary rate 8—15 miles.

The steam-engine employed to propel a vessel does not differ essentially from any other; but some modifications are necessary to suit the special circumstances under which they work. In ships of war, the cylinders are generally placed horizontally, and the whole machinery kept below the level of the water-line; in merchant-vessels, vertical engines are more commonly used, with the cylinders inverted, placed right above the propeller-shaft. For working paddle-wheels, oscillating engines were, on the whole, the most common. See STEAM-ENGINE; PADDLE-WHEEL; SCREW-PROPELLER.*

* The application of the screw to the propulsion of vessels is well known to have been tried at least before the middle of the 18th century. In the *Traité de Navire* by Bouguer (Paris, 1746), it is stated that 'revolving arms like the vanes of a windmill were tried for the propulsion of vessels.' In 1751, Daniel Bernouilli, the famous mathematician, in his *Recueil d'Ouvrages Curieux*, describes and gives drawings of the screw-propeller. In 1770, James Watt mentions a screw propeller in a letter to Dr. Small, who replies that he had tried it. In 1776, D. Bushnell, an American, in an account of a submarine vessel, describes a screw-propeller for moving it. In 1804, J. Stevens tried at New York a vessel fitted with a screw propeller driven by a steam-engine made by Boulton and Watt. This appears to be the first attempt at propulsion by the screw with steam as a moving power. Colonel Beaufoy has described a spiral oar or screw-propeller, with two spiral rims fixed on arms, which he had seen used in China about the year 1780. In the present century, hundreds of patents have been taken out for screw-propellers; but costly experience has contributed more to the present perfection of the screw than any recent 'inventions.' The name most widely known in connection with the introduction of the screw-propeller is that of Mr. (afterwards Sir) Francis Pettit Smith, a farmer near London, who took out a patent in May, 1836, for a screw-propeller. This gentleman who was by no means the first who tried to get the screw into use, was fortunate enough to obtain the assistance of influential capitalists, and after various trials on a small scale, he fitted up the *Archimedes*, a regular sea going vessel. The complete success of this the first real trial on a large scale, gave to Mr. Smith a position

STEA'RIC ACID AND STE'ARIN. The composition of stearic acid is represented by the formula $C_{36}H_{36}O_3.HO$; this acid being one of the solid fatty acids represented by the general formula $C_nH_{n-1}O_3.HO$. It exists as a glyceride (stearin) in most fats, and is especially abundant in the more solid kinds, such as mutton-suet. It is readily obtained by saponifying suet, and decomposing the hot solution of the soap by tartaric acid. The oily acids which are thus liberated are compressed between hot plates, by which means most of the Oleic Acid (q. v.) which is present is expelled. The solid residue is then to be repeatedly crystallized from alcohol, and afterwards from ether till the fusing-point becomes constant at 159°. If the final solution is allowed to cool slowly, the acid is deposited in beautiful, colorless transparent rhombic plates. After fusion, it cools into a wax-like, glistening, crystalline mass, devoid of taste or smell. It is insoluble in water, on which it floats, but dissolves in alcohol and ether, its solution reddening litmus powerfully. When heated above its fusing-point, it becomes decomposed into palmitic acid ($C_{32}H_{31}O_3$,-HO), palmiton ($C_{62}H_{62}O_2$), and an oily hydro-carbon. Stearic acid forms both normal and acid salts. The only normal stearates which are soluble in water are the stearates of the alkalies, whose solutions are frothy and form a lather, but on the addition of an excess of water, separate into an acid salt which is deposited in silky crystalline plates, and the free alkali which remains in solution. The stearates of the alkalies are also soluble in alcohol.

Chloride of sodium (common salt) has the property of separating the alkaline stearates from their solution. The stearates of the alkalies are the principal constituents of the different kinds of soap. The other stearates are insoluble. Stearate of lead, which is one of the constituents of lead-plaster, is readily formed by mixing solutions of stearate of soda and acetate of lead, when the stearate of lead falls as a heavy amorphous precipitate, sparingly soluble in alcohol or ether, but dissolving freely in oil of turpentine.

The *Bassic Acid* extracted from the oil of the seeds of *Bassia latifolia*, a tree growing in the Himalaya, and the *Stearophanic Acid* obtained from the berries of *Monospermum Cocculus*, are identical with stearic acid.

The use of stearic acid in the manufacture of candles is described under the head CANDLE. See also OILS.

STEARO'PTEN. See OILS.

STE'ATITE, or SOAP-STONE, a mineral principally composed of silica and magnesia, with more or less alumina and water. It is found massive, or sometimes assuming the forms of the crystals of other minerals which it has replaced. It is plentiful in many parts of the world, and is found in various parts of Britain. It is generally white, reddish white, or yellow. It is soft and greasy to the touch, easily cut, but broken with difficulty. It is used in the manufacture of porcelain. It writes readily on glass, and is used by glaziers for marking plates of glass before they are cut with the diamond. Tailors use it for marking cloth before they cut it. It is also used by shoemakers, to give unctuosity to the heels of stockings, that new boots may more easily be tried on. It is sold for such purposes under the names of Briançon Chalk, French Chalk, and Venice Talc. It readily absorbs oil or grease, and is used in powder for extracting spots of them from silken and woolen stuffs. It is the basis of Rouge (q. v.). It is used for imitating engraved stones, being easily cut, and afterwards hardened by heat; after which, it may be colored by metallic solutions.

The *Agalmatolite* or *Figure-stone* of China is a kind of S., containing a little potash. Exquisite specimens of Chinese workmanship in this material are now familiar to every one. The earth eaten by the savages of the banks of the Orinoco and of New Caledonia is a kind of soft steatite.

STEELL, SIR JOHN, R. S. A., an eminent Scottish sculptor, the son of a carver and gilder in Edinburgh, was born at Aberdeen in 1804. He received his education as an artist at the Edinburgh Academy, and afterwards at Rome. On returning thence in 1830, he executed a colossal group of 'Alexander and Bucephalus,' which was instantly recognized as a work of great merit. The promise of this early work he has since amply fulfilled; and is now admitted to stand in the front rank of his profession. His chief works are in Edinburgh: the colossal figure of the Queen crowning the front of the Royal Institution, which procured him the honorary appointment of Sculptor to Her Majesty in Scotland; the statue of Scott in the Scott monument, a commission which was won in competition; the equestrian statue of the Duke of Wellington (1852); statues of Professor Wilson and Allan Ramsay (1865); and the equestrian statue of Prince Albert, at the inauguration of which in 1876 S. was knighted.

STEEL. See IRON.

STEELBOW, in Scotch Law, means goods, such as corn, cattle, straw, and implements of husbandry, delivered by the landlord to his tenant, by means of which the latter is enabled to stock and labor the farm, and in consideration of which he becomes bound to return articles equal in quantity and quality at the expiration of the lease.

STEELE, SIR RICHARD, was born in Dublin in the year 1671. His father, who held the office of secretary to the Duke of Ormond, was of an English family, but his mother was Irish; and the son appears to have inherited from her the impulsive ardor, tenderness, bright fancy, and reckless profusion immemorially ascribed to the Irish national character. He was educated at the Charter-house School, along with his illustrious friend Addison, and from thence was removed to Merton College, Oxford. Leaving college without taking a degree, he enlisted in the Horse Guards, for which imprudence he was disinherited by a rich relation of his mother, who had named him as heir to an estate in Wexford. In the army, he rose to the rank of captain, but was gay, thoughtless, and dissipated—always sinning and repenting, as he himself confesses. To impose a check on his irregularities, he wrote a religious treatise, *The Christian Hero*, published in 1701, the design of which was to show that no principles but those of religion are sufficient to make a great man. This public profession of seriousness had little effect on the volatile captain, and he next took to writing comedies.

In 1702, he produced *The Funeral, or Grief à la Mode;* in 1703, *The Tender Husband;* and in 1704, *The Lying Lover*—the last a decided failure. About the same time, he obtained some fortune by marrying a West Indian lady, who survived the marriage only a few months; and in 1706, he got the appointment of Gazetteer, with a salary of £300 per annum, and also the post of Gentleman Usher to Prince George, which added another £100 to his income. In the following year (September 9, 1707), he married a Welsh lady, Mary Scurlock, who figures conspicuously in his correspondence as the 'Dearest Being on Earth,' 'Dear Prue,' and 'Dear Wife,' to whom he addressed some 400 letters—admiring, apologetic, and passionate. A course of extravagance—town and country houses, horses and chariots—soon involved the pair in difficulties. Mrs. Steele had a fortune of £400 a year, and was thrifty; but the lady's mother had a life-interest in the estate, and was hard and uncongenial. Addison gave a loan of £1000 which was repaid within a twelvemonth; but he made other advances, secured by a bond on house and furniture. He put the bond in execution, sold the house and furniture, and remitted the surplus to his imprudent friend. For this seeming harshness, Addison has been blamed; but it rests on good authority that the sufferer himself entertained no such feeling: he regarded the incident as a warning meant to do him service, and he met his friend again with his wonted composure and gaiety.

In 1709, S. commenced *The Tatler*, a periodical published thrice a week, containing short essays on life and manners, town gossip or *tattle*, and articles of foreign and domestic news, for which S.'s appointment of Gazetteer furnished him with peculiar facilities. Addison joined cordially in this publication, and still more effectively in its successor, *The Spectator*, a daily literary journal of a higher tone and character, which was continued with unexampled success through 635 numbers. A third miscellany of the same kind, *The Guardian*, was extended to 175 numbers. S. afterwards attempted other periodicals, as *The Lover*, *The Reader*, &c., but these were short-lived. His fame rests on his essays in the *Tatler*, *Spectator*, and *Guardian*, to which he contributed respectively 188, 240, and 82 papers. In the keen political strife of that venal age, S. fought courageously and honestly for the Hanover succession and Whig principles. He lost his office of Gazetteer, and was expelled the House of Commons, for writing a pamphlet called *The Crisis*, in which he warned the nation that the Protestant cause was in danger. But when Queen Anne died, and the Whigs were again triumphant, S. participated in the royal favor. He obtained an appointment in the king's household, was elected M.P. for Boroughbridge, and received the honor of knighthood.

In 1717, S. was nominated one of the commissioners for the forfeited estates in Scotland, and he seems to have made four annual visits to Edinburgh on the business of this commission. He was led into a controversy with Addison, a few weeks before the death of the latter, on the once-famous Peerage Bill—a proposal by

which he had well earned, not by his invention or improvement of the screw-propeller, but by demonstrating to the world on a large scale its capabilities. Other inventors were before him in point of time, but most of them confined their operations to trials of models, or, at most, to small boats fitted with screws which were driven by hand. Mr. Robert Wilson made and exhibited working models of a vessel propelled by a screw in the years 1821—1825, and for several years afterwards his schemes were before a number of public bodies in Scotland. The successful introduction of a propeller with several separate blades, each forming a small portion of a complete helix (the form now universally used), is claimed for Mr. Lowe, Mr. Henry Wimshurst, and others. Sir Francis Pettit Smith's propeller in the *Archimedes* had one blade forming a complete spiral, a form which was speedily abandoned. In addition to the gentlemen mentioned, Mr. Bennett Woodcroft, Mr. Robert Griffiths, and others, have contributed greatly to the introduction and improvement of the screw-propeller; but as Sir F. P. Smith, aided by his moneyed associates, was the first to put the screw into a big ship, and boldly go to sea in her, the world will continue to give him credit for introducing the screw-propeller into actual use, and sometimes, but with less justice, he will get credit for having invented it.

ministers for restraining the king from any new creation of peers, except upon the extinction of an old family. On this question S. took the side of the crown, and fairly beat his opponent in argument and in temper, besides enjoying the triumph of seeing the bill thrown out. The friends, alas! met no more. The survivor struggled on among controversies, embarrassments, and lawsuits; he was patentee of Drury Lane Theater; and in 1722, he produced his admirable and successful comedy of *The Conscious Lovers*. His health now rapidly failed. His wife had died in 1718, but he had children to solace his decline. The last three years of his life were spent in retirement in Wales, and there his chequered existence came to a close: he died at Llangunnor, near Carmarthen, on the 21st of September 1729.

The essays of S. have eclipsed his dramas. His Bickerstaff, the Spectator Club, allegories, and short tales have the true, ever-living, dramatic spirit. In taste and delicate humor, he was greatly inferior to Addison; but in invention and insight into human character and motives, he was fully his equal. He knew the world better, and he sympathized with almost every phase of life and character except meanness and cruelty. He seems to have considered it to be his special mission to reform the minor vices and absurdities of English society. If his satire had been more keen and trenchant, or his moral lessons more formal and didactic, he could not have succeeded as he did: his essays were just adapted to the times—they insinuated morality and benevolence, and supplied innocent enjoyment mingled with instruction. The lively, natural writer and companion is never lost in the teacher, nor the gay captain of horse wholly absorbed in the author.

STEEL TOYS. This is a manufacturing term much used in Birmingham, London, and elsewhere. It has a somewhat different meaning to that which would at first sight be given to it. Steel toys are small articles, such as cork-screws, buckles, boot-hooks, and a great variety of similar objects, when made of polished steel. Birmingham and Sheffield are the chief seats of this industry, which employs a large number of operatives and considerable capital.

STEE'LYARD. See BALANCE.

STEEN, JAN, a celebrated Dutch painter, was born in 1626, or according to others in 1636, at Leyden, where his father was a brewer. He showed an early predilection for art, which led to his being apprenticed to a German painter, Nicholas Knupfer of Utrecht. Subsequently he became a pupil of Van Goyen, whose daughter Margaret he married. Very soon his repute became established. As he worked, however, in a slow and elaborate manner, his gains were insufficient, and he started a brewery at Delft. This enterprise promised fairly; but, according to tradition, he was by no means of steady business habits, and so bemused himself with his own beer that very soon he brewed no more of it. Little that is certain appears to be known regarding the subsequent life of S., but numerous unauthenticated anecdotes are in vogue, which, if it could be shown that they were true, would prove him to be a wretched drunkard; but a late biographer, Van Westerheene, throws considerable doubt on the accuracy of the popular impression. S. died in 1679 or 1689, leaving his family in very destitute case.

As an artist of the Dutch school he ranks high; and his works are now much valued. In humor and spirit they are scarcely surpassed, and their coloring is clear, fresh, and delicate. At times he attempted historical subjects, but his success in these was not great. It was in homely and domestic scenes that his genius truly exhibited itself; and in this field he has scarcely since been quite equalled.

STEEPLE, the tower and spire, lantern, or other superstructure attached to a church. These are usually of stone, but in some cases are carried up from the floor in massive wooden framing.

STEEPLE-CHASE. This singular term is used to designate a kind of horse-race, run not on a prepared course, but across fields, hedges, ditches, and obstacles of every kind that may happen to be in the way. The name and practice are said to have both originated in a party of unsuccessful fox-hunters, on their return home, agreeing to try a race towards the steeple of a village church, the first who could touch the church with his whip to be the winner. This kind of sport soon became popular; and matches were made and sweepstakes entered into—the requirements of the course being simply two flagstaffs placed about two miles apart, from one of which the competitors started, made their way to the other, and returned to the starting-point. Each rider was allowed to go and come as he chose, but the country was often selected on account of its difficulty; high and strong fences, deep and broad ditches, and sometimes even swollen rivers having to be crossed and recrossed. Then came the more regular steeple-chase of modern times over a course marked out by flags, between which the rider must pass in order to win the race. This improvement was introduced about the end of last century, and no further change took place till 1841, when *handicapping* began. This consists in the weighting of horses according to their supposed merits, without reference to age, size, or sex.

The first handicap steeple-chase was run at Newport-Pagnell on April 20, 1841, and the sport has since become more and more popular in England, most of the spring and autumn meetings having their steeple-chases, for valuable stakes. Great crowds of people always attend, the very danger of the sport seeming to increase its attractiveness. Serious accidents are not unfrequent; and great courage, coolness, resolution, and judgment are requisite on the part of the rider in a steeple-chase.—The name is also applied to similar races for men.

STEE'RAGE, in a vessel, is the lowest class or accommodation for passengers.

STEERING is the act of directing the ship's course by means of the Helm (q. v.). It is bad steering when the ship's head is allowed to oscillate first on one side and then on the other of the course she has to pursue. By such steering the distance to be traversed is increased, and a greater resistance is encountered, the sea being struck more obliquely.

STEIN, HEINRICH FRIEDRICH KARL, BARON VON, one of the greatest statesmen that ever conducted Prussian affairs, belonged to an old Rhenish-Franconian family, and was born at Nassau, October 26, 1757. He studied at Göttingen from 1773 to 1777, entered the service of Prussia in 1778, and in 1784, had risen to be at the head of the department of mines for Westphalia. In 1786, he visited England in company with his friends, the Counts von Redern and Schlahberndorf, and carefully studied the institutions of that country, for which he conceived a high admiration, and sought to introduce them at a later period into Prussia.

After several minor preferments, he was appointed, in 1797, president of the Westphalian chambers, where he displayed rare administrative talent. In October 1804, he entered the Prussian ministry as chief of the department of indirect imposts, taxes, manufactures, and commerce. In this capacity he effected important ameliorations, particularly by abolishing various restrictions on the internal trade of the nation; yet to his great grief and vexation he found himself incapable of modifying the policy that resulted in the French invasion and conquest. Of a thoroughly conservative and religious disposition, full of pious reverence for the past, so far as it possessed vital energy, but strongly opposed to bureaucracy and military despotism; recognizing in the self-governing powers of communities and provinces the only practical guarantee of national liberty, yet, as a baron of the empire, hostile to the anarchic sovereignty of little states, he occupied a political standpoint which procured for him many adversaries and few friends. In 1807, he was dismissed from office by the king, and withdrew to his estate in Nassau; But the peace of Tilsit opened the eyes of his sovereign to the wisdom of S.'s policy, and in less than seven months he was recalled, with the approbation of Napoleon, who had as yet no idea of the deep and earnest patriotism of the minister.

S.'s industry was untiring. Seeing clearly that, in a military point of view, Prussia was powerless for the moment, he set about developing her internal resources by attempting a series of administrative and political reforms, known as *Stein's System*—the principal of which were the abolition of serfage, with indemnification to the territorial lords; the subjection of the nobles to manorial imposts; equality of orders in the sight of the law; the universal obligation of military service; promotion in the state by merit alone, without distinction of caste; and the establishment of a municipal system analogous to that of England. Some of these reforms were carried out by S., and others by his successor, Hardenberg (q. v.). Meanwhile, he had become suspected by Napoleon. Among other things, an intercepted letter was brought to the French emperor, in which his policy was sharply criticised. S. was obliged to resign (November, 1808), and retired to Austria, where he became the center of a secret national society—the *Tugendbund*. Napoleon, who bitterly hated patriots that stood in his way, confiscated his property. In 1812, S. was summoned to Russia by the Emperor Alexander, and contributed by his counsels to prepare the coalition against Napoleon.

After the march of the allies into Saxony, he was appointed president of the council of all the German States; was a leader in all the military diplomacy of that stirring time up to the Congresses of Vienna and Aix-la-Chapelle, in which, however, he took no part, owing to the intrigues of the Bavarian minister, acting for the lesser states of Germany, who knew well that he did not look with a favorable eye on their anarchic autonomy. The absolutists were also against him. S.'s active political career was now finished; henceforth he enjoyed some honorable functions, but no power, and died at Frücht, July 29, 1831.—See Pertz's *Leben des Freiherrn von Stein* (1855); Professor Seeley's *Life and Times of S.* (1879). His correspondence with Humboldt,

Gneisenau, Eichhorn, Niebuhr, &c., is extremely valuable for the political history of the period.

STEI'NBOK. See BOUQUETIN.

STELLA'RIA. See STITCHWORT.

STE'LLERINE (*Rytina*), a genus of *Sirenia*, of the family *Manatidæ* (q. v.), of which only one species is known (*R. gigas*), about 25 feet in length, a native of Behring's Strait, and never observed since the middle of last century, so that it is supposed to be extinct.

STE'LVIO, PASS OF THE (Ger. *Stilfserjoch*), the highest carriage-road in Europe (9176 feet above the sea-level), leads from Bormio, on the Italian side of the Tyrolese Alps, near the head of the Valteline, to Glurns on the Austrian side. It forms part of the great road between Milan and Innsbruck, and was completed by the Austrian Government in 1828, at an expense of 3,000,000 florins. The praise bestowed on it in Murray's *Handbook for Southern Germany* is well deserved: 'Whether we consider the boldness of the design, the difficulties of its execution, from the great height and exposure to storms and avalanches, or the grandeur of the scenery through which it passes, the route of the Stelvio is the most remarkable in Europe.'

STEM, in Botany, that part of the plant which, arising from the surface of the ground, and shooting upwards as the root shoots downwards, bears the leaves and flowers. Stems are either simple or branched. They are herbaceous or woody, solid or hollow, jointed or unjointed. Sometimes they are weak so as to be procumbent, although more generally firm and erect; sometimes weak stems are twining, or they are upheld in various other ways by the climbing habit of the plant. Stems are generally round, but sometimes compressed or angular. The arrangement of the leaves and branches, in reference to the stem, is symmetrical, but plants differ from each other in the nature of this arrangement. In the branching of trees, the symmetrical arrangement is often lost, as to the principal branches, in consequence of the death of some of them. In many plants the stem is obsolete, or so abbreviated as to be inconspicuous, forming a mere neck—the *crown of the root*—where the leaves and flower-stalks spring as at once from the root. Very important differences in the structure of stems distinguish the three great classes of plants—Acrogenous (q. v.), Endogenous (q. v.), and Exogenous (q. v.). Stems sometimes creep along the ground, or even under the ground, when they receive the name *rhizome* or *root-stock*.

STEM, of a ship, is that very powerful piece, or combination, of timber, which, being scarfed to the fore-end of the keel, rises nearly perpendicularly to form the bow and cutwater. To it are rabbeted the fore-ends of the planks. It is backed by an equally powerful timber called the Stemson, bearing the same relation to it as the Keelson (q. v.) does to the keel. See also SHIP-BUILDING.

STE'NCILLING, a method of printing letters or designs. The process consists in cutting out the pattern in a thin plate, usually of metal; this is then laid on the surface intended to receive it, and the color is rubbed into the cut space with a brush, the plate preventing the contact of the color, except on the space cut out. It is much used for wall and other surface-decoration, as it is a rapid and cheap process.

STE'NDAL, a town of Prussian Saxony, 38 miles north-north-east of Magdeburg. Pop. (1880) 12,870. It has manufactures of woolens, cottons, tapestries, tobacco, gloves, &c.

STENO, NICHOLAS, a distinguished anatomist and geologist, was born at Copenhagen in 1638. He had long been famed for his anatomical discoveries, when, in 1667, he devoted himself to geology, acquiring the right to be regarded as the father of palæontological science. He lived much in Italy, and became a Catholic. Latterly he wrote several religious and controversial works, and was made a bishop *in partibus* by the Pope. He died at Schwerin, November 25, 1687. See *Nature*, Vol. xxv.

STENO'GRAPHY. See SHORTHAND.

STEPHEN, ST., THE DEACON, called also the Proto-martyr, or earliest of the Christian martyrs, was one of the seven deacons named in Acts, chap. vi., where his martyrdom is also given. His festival is fixed during the festivals which accompany that of Christmas. His relics were believed to have been discovered in the beginning of the 5th c., the 'discovery' being commemorated by a festival held on the 3d of August.—In the calendar of the Roman Catholic Church are several other saints of the same name, of whom perhaps the most remarkable is Stephen, king of Hungary in the early part of the 11th c. He died in 1038.

STEPHEN, the name of ten popes of the Roman Catholic Church. It is only necessary to refer in detail to the following. STEPHEN I. was the successor of Lucius III., in 253, and his pontificate (253—257) is memorable as affording a topic for the historians who discuss the question as to the early evidences of a Roman *primacy*. The history of Stephen I. is urged as an argument by each party in support of its own view. The advocates of the primacy infer, from several examples of the deposition of bishops by S. in various places, that a power equivalent to the modern primacy of Rome was even then acknowledged. The adversaries of the primacy contend that the resistance offered to S. by Cyprian (q. v.), on the rebaptizing of heretics, is altogether irreconcilable with the general recognition in the 3d c. of any supremacy on the part of the bishop of Rome.—STEPHEN III. plays a most important part in the history of the temporal sovereignty of the Roman see. He was a native of Rome, and was in possession of the see during the occupation (which practically dates from the year 752) of Ravenna, the Exarchate, and the Pentapolis, by Astolphus, king of the Lombards.

That king having invaded Rome, and the Byzantine emperor, Constantine Copronymos, having left unheeded the appeals of S. and the Romans for succor, S. had recourse to Pepin, king of the Franks. The latter in vain sent legates to Astolphus, and the pope returned to France with the legates to solicit in person the aid of the Frank monarch, whom he solemnly crowned. Pepin agreed to compel the Lombards to withdraw from these provinces (which form the portion of the states lately in occupation of the Roman see known as the 'Legations'), and to bestow them on the see of Peter. The Lombard king made a promise to that effect; but on Pepin's withdrawal, again renewed his pretensions, and marched upon Rome. S. therefore again recalled Pepin in a most curious letter written in the name and person of St. Peter, an invitation with which Pepin at once complied; and having again forced Astolphus to withdraw, he again (notwithstanding a demand from the Byzantine emperor for their restoration to the empire) reinstated the Roman see in its sovereign rights. S. died in 757.—STEPHEN VII., elected in 896, has supplied to historians much matter of discussion, from his strange proceedings in disinterring the corpse of his penultimate predecessor, Formosus, stripping it of its pontifical garments, and condemning it, after a juridical procedure, to lay burial. The circumstances of this curious conflict are not fully understood.—STEPHEN X. was one of the remarkable series of reforming popes in the 11th c., who are believed to have been elected under the influence of the celebrated Hildebrand, and who, by their energetic rule, prepared the way for that great scheme of ecclesiastical organization of which the pontificate of that eminent man, under the name of Gregory VII. (q. v.), was the final development.

It ought to be observed that, although in the series of the POPES (q. v.) printed in this *Encyclopædia* ten pontiffs named Stephen are recited, other catalogues reckon but nine; the discrepancy arising from the omission by some of Stephen II., who was elected in 753. This pontiff died before consecration, and is therefore by some excluded from the series of popes; but, as his election was complete and canonical, we have included his name in our general catalogue.

STEPHEN, king of England, was the third son of Stephen, Count of Blois, by Adèle, or Alise, daughter of William the Conqueror, and was consequently nephew of Henry I., and cousin of Matilda, daughter of Henry. He was born in 1105, brought over to England at an early age, and became a favorite with his uncle, who bestowed on him large estates, both in that country and in Normandy, and procured for him a marriage with Mahout, or Matilda, daughter of Eustace, third Count of Boulogne, and younger brother of the famous Godfrey of Bouillon. By this marriage S. not only inherited the earldom of Boulogne on the death of his father-in-law (1125), but also became related to the royal family of Scotland, for his wife's mother, Maria, was a daughter of Malcolm Canmore. When his uncle Henry resolved to settle the crown on his daughter Matilda, whose first husband was Henry V., emperor of Germany (whence she is often spoken of as the 'Empress Maud'), he naturally relied on his project receiving the support of his nephew; and at a council held in London, January 1127, S. along with all the other dignitaries of the land, lay and ecclesiastical, took the oath of fealty to Maud.

A few months later, the widowed empress married Geoffrey Plantagenet (q. v.). On the death of Henry I. (December 1, 1135), S., knowing well the temper and wish of the English people, hurried over to England from Normandy, where he had been in attendance on his dying uncle, and before the year was out had got himself surrounded by a powerful body of the nobles and clergy and crowned at Westminster. His usurpation of the throne was confirmed by a bull of Pope Innocent. But S. was doomed to find his crown a crown of thorns. Although a gallant, generous, handsome prince, immeasurably superior in personal and royal virtues to Maud (who was suspected of having murdered her first husband, who quarelled with her second, and was altogether a fiery, insolent, unwise, and exasperating female); yet it must not be forgotten that on S. rests the responsibility of causing a civil war as sanguinary, if not as protracted, as the famous *Wars of the Roses*. Listen to the *Saxon Chronicle*: 'In this king's time, all was dissension and evil and rapine. . . . . Thou mightest go

a whole day's journey, and not find a man sitting in a town, nor an acre of land tilled. The poor died of hunger, and those who had been men well-to-do begged for bread. Never was more mischief done by heathen invaders. . . . . To till the ground was to plough the sands of the sea. This lasted the nineteen years that Stephen was king, and it grew continually worse.'

We have not space to narrate in detail the struggle of these nineteen years. It is enough to say, that in February 1141, after five years of the hardest fighting imaginable—against David of Scotland, uncle of Maud, who had taken up arms for his niece (see STANDARD, BATTLE OF THE); against Robert, Earl of Gloucester, natural son of the late King Henry, who had also raised the standard of his half-sister; against individual nobles who simply wished to live in anarchic and barbarous independence; and finally, against the power of the church, which he vainly sought to diminish—he was taken prisoner by the Earl of Gloucester, and placed in chains in the Castle of Bristol. Maud was now elected queen by her own party, but her rapacity and other bad qualities soon made her rule intolerable, and the wife of the imprisoned S. (also called Maud or Matilda) found it possible to continue the war, by the help of the Londoners, who were staunch adherents of her husband. S. obtained his liberty in exchange for the Earl of Gloucester, who had fallen into the hands of S.'s friends at Winchester, and the war was resumed with greater violence than ever. The death of the Earl of Gloucester, in 1146, forced Maud to take refuge in Normandy; but a conspiracy of nobles, headed by Ranulph, Earl of Chester, and another quarrel with the church, kept S.'s hands as full of work as before, and no sooner were these matters settled, than Maud's son, young prince Henry, appeared in England (1153), at the head of an army to support his claim to the throne. Fortunately for the nation, so sadly wasted and desolated, a compromise was effected between the two rivals, which saved the necessity of further bloodshed—S. agreeing to acknowledge Henry as his successor. S. died at Dover the year after (25th October 1154).

SPEPHENS (Fr. *Estienne*). The family of the celebrated printers and publishers of this name (descended from a noble Provençal family) is found settled at Paris towards 1500 in the person of Henry Stephens, supposed to have been born about 1470, and died in 1520. In Paris, Henry carried on the business of printer and bookseller for upwards of twenty years. In 1526, Robert, his second son, born in 1503, is found in possession of the business. Every year of Robert's life is marked by the issue from his printing-press of several volumes, many of them masterpieces of art, and all of them surpassing anything of the kind previously seen in France. He was at once printer, publisher, commentator, and author. Though prosperous, he showed unmistakably that truth—or that which to him was truth—was of more value in his eyes than worldly gain. Having secretly become a convert to the doctrines of the Reformation, he endeavored for some time to reconcile his convictions with the outward demeanor required by his position. But the convictions were too strong, or the nature of the man too truth-loving. His Bible of 1545, and his Greek Testament of 1549, each drew down upon him a public prosecution; and though the prosecutions failed legally, they were disastrous to his private fortune. Having first sent his family to Geneva, he followed them there in 1549. Robert, his second son, shortly afterwards returned to Paris where he resumed his father's business, returning to the Roman Catholic church.

In flying from Paris to Geneva, the S. family found that they had but exchanged Roman Catholic for Protestant persecution.

Henry the second, born at Paris in 1528, and succeeding his father Robert on his death in 1559, was repeatedly called before the council, reprimanded, ordered to print cancels, and excommunicated. Though Henry possessed the same literary industry and ability as his father, he was unfortunately deficient in his father's practical turn of mind. Devoted to his art and to his calling, he seems to have been utterly wanting in worldly prudence. In two years we find that he had revised and published more than 4000 pages of Greek text; while at the same time he was writing his *Apologia pro Herodoto*, a work of formidable length and learning. Rendered nervous and irritable by an overworked brain, and by pecuniary difficulties, which were gathering fast around him, the petty surveillance and censorship of the pious pastors of Geneva became intolerable to him. Traveling, originally undertaken from literary curiosity, grew into a necessity of life. In 1578, he visited Paris, where for several years he became a hanger-on of the court of Henry III., who bestowed upon him a pension, which the state of the royal exchequer rendered merely a nominal one. Quitting Paris, he wandered in poverty over Europe, his own family often ignorant of where he was to be found. He died at Lyon in 1598. Great as a publisher and commentator, Henry S. does not seem to have possessed much power as an original thinker. His mastery of Greek seems to have been almost complete, and as a critic of the French language he is still esteemed in France.—See Feugère *Caractères et Portraits* (1864); *Quarterly Review* (1865); article in the *Biographie Générale*); Bernard, *Les Estiennes* (1856); Renouard, *L'Imprimerie des Etiennes*.

STEPHENSON, GEORGE, was born at Wylam, eight miles from Newcastle, on the 9th of June 1781, in circumstances of great poverty, his father having to maintain a family of six children on 12*s*. per week, earned by tending a colliery-engine at Wylam, near Newcastle. George's first employment was herding cows at 2*d*. per day, from which he was promoted to hoeing turnips at 4*d*.; subsequently, he was appointed fireman at Midmill Colliery, and at 15 we find him rejoicing on his salary being raised to 12*s*. a week. As fireman, he applied himself to diligent study of the steam-engine, taking his machine to pieces during his leisure-hours, and thus gaining a thorough practical knowledge of it. At Black Callerton Colliery, in 1801, by dint of mending shoes and cleaning watches, in addition to his regular employment, S. contrived to save his first guinea. At 21, he had saved as much as enabled him to furnish a cottage in a humble way, and on 28th November 1802, he was married to a young woman named Fanny Henderson. She died in 1804, while her husband was brakesman at Killingworth Colliery. The early life of S. presents a record, whose interest cannot be surpassed, of a contest between determined purpose, industry, and sagacity on the one hand, against poverty on the other. Slowly, inch by inch, we find the inward forces gaining ground upon the outward. Out of his humble gains he contrived to pay 4*d*. a week for lessons in reading, writing, and arithmetic, which were conned over at night, and mastered by the light of his engine-fire. On one occasion, indeed, so hard had the tide gone against him, that even he had nearly given way to despair. 'I wept bitterly,' he says, in allusion to an intention he had formed of emigrating, —'for I knew not where my lot in life might be cast.'

In 1815, the invention of a colliery safety-lamp, the 'Geordie,' brought his name before the public. The fact of his invention being almost simultaneous with that of Sir H. Davy, gave rise to a long controversy between their respective friends and supporters. In 1819, S. married his second wife, Elizabeth Hindmarsh, the daughter of a farmer at Black Callerton. It was at Killingworth Colliery that he constructed his first locomotive. At first, it was not very efficient; but, subsequently, the grand improvement of the 'steam-blast' carried his experiment to a triumphant issue. Further improvements followed, and in 1821 S. was appointed engineer for the construction of the Stockton and Darlington Railway; the line, on its completion, being partially worked by means of his great invention. The rapid growth of the trade of South Lancashire, together with the unpopular management of the Bridgewater Canal, gave rise, in 1821, to the project of a railway between Liverpool and Manchester. S. was chosen engineer. That he proposed to work the line with an engine which was to go at the rate of 12 miles an hour, was a fact held up as of itself sufficient to stamp the project as a bubble. 'Twelve miles an hour!' exclaimed the *Quarterly Review*—'as well trust one's self to be fired off on a Congreve rocket.'

When the bill ultimately passed, on 16th March 1826, S. was appointed principal engineer, with a salary of £1000 a year. After inconceivable difficulties, the line was completed in 1829. There then ensued the memorable competition of engines, resulting in the complete triumph of Mr. S.'s 'Rocket,' which, to the astonishment of every one except himself, was found capable of travelling at the till then undreamt-of rate of 35 miles an hour. 'Now,' exclaimed one of the directors, 'George Stephenson has at last delivered himself.' While occupied in carrying out the vast system of railway which soon overspread the country, S.'s home was at Alton Grange, near Leicester. He saw but little of it, however, as he was often traveling on business for weeks at a time. During the three years ending 1837, he was principal engineer on the North Midland, York and North Midland, Manchester and Leeds, Birmingham and Derby, and Sheffield and Rotherham Railways. In 1836 alone, 214 miles of railway were put under his direction, involving a capital of five millions. He has been known to dictate reports and letters for twelve continuous hours. But in the midst of his immense business, his heart remained as youthful as ever. In spring, he would snatch a day for bird-nesting or gardening; in autumn, nutting was still a favorite recreation. We find him even at this time writing a touching account to his son of a pair of robins. Strong as he had shown himself when the world was all against him, he was not less so in the midst of his success.

During the railway mania, his offices in London were crowded every day with men of every rank and condition, eager to strengthen their prospectuses by the weight of his name. Where he disapproved—and at this time he almost always did disapprove—he invariably declined, though by acceding he might have made enormous gain; but to make money without labor or honor had no charm for Stephenson. In the autumn of 1845, he visited Belgium and Spain for professional purposes. On his way home he

was seized with pleurisy, from which attack he does not seem ever to have thoroughly recovered. He occupied his declining years with the quiet pursuits of a country gentleman, indulging his love of nature, which, through all his busy life, had never left him. He died at his country-seat of Tapton on 12th August 1848. The leading feature of his mind was honesty of purpose, and determination in carrying it out. 'I have fought for the locomotive single-handed for nearly twenty years,' he says; 'I put up with every rebuff, determined not to be put down.' Towards trickery and affectation he never concealed his contempt, while honest merit never appealed to his liberality in vain.—See *Lives of Engineers*, by Samuel Smiles, vol. iii. (Lond. 1862).

STEPHENSON, ROBERT, only son of George Stephenson, was born on the 16th October 1803. When a boy, he attended a school in Newcastle. In 1820, his father's improving circumstances enabled him to send Robert to the university of Edinburgh, where he seems to have made excellent use of his time. In 1823, we find him assisting his father in the survey for the Stockton and Darlington Railway. Subsequently, he took an active part in the locomotive engine-works started by his father at Newcastle. In June 1824, he went to Mariquita, in South America, on an engineering appointment; but this not suiting him, at the end of three years he returned home by the United States and Canada. He then assumed the management of the Newcastle business. During the discussion as to the power to be employed on the Liverpool and Manchester line, he was in constant communication with his father, to whom his quick perception and rapid judgment were of great assistance. Shortly after the completion of this line, he was appointed engineer of the Leicester and Swanington Railway. Subsequently, he was appointed joint managing engineer, along with his father, of the London and Birmingham line, the execution of which immense work was ultimately almost wholly intrusted to him. In 1829, he married Frances, daughter of John Sanderson, merchant in London. She died in 1842 without issue; and he did not marry again. The London and Birmingham line was completed in such a manner as to raise S. to the very highest rank in his profession. Business now flowed in upon him. In one parliamentary session we find him engaged in 33 new schemes. Projectors thought themselves fortunate if they could procure his services on any terms. The work which he got through was enormous, and his gains large beyond what had then been known in his profession.

The Britannia Tubular Bridge, of which undertaking Robert S. was the master spirit, is one of the most remarkable monuments of the enterprise and engineering skill of the present century. It was completed on 5th March 1850, at a cost of £234,450. S. lived to repeat his splendid achievement in the bridge across the St. Lawrence at Montreal, and in the two bridges across the Nile at Damietta. In 1847, he was returned to the House of Commons as member for Whitby. On 15th August 1849, he completed the high-level bridge at Newcastle, and in the following year the great viaduct across the Tweed at Berwick. In 1855, the emperor of the French decorated him with the Legion of Honor. At home, the university of Oxford made him D.C.L. In the same year he was elected President of the Institute of Civil Engineers. The immense amount of work which he went through both at home and abroad proved too much for his constitution, originally delicate; while in Norway, in 1859, he was seized by the illness which soon afterwards ended his illustrious career. He died on 12th October 1859. He was buried in Westminster Abbey. It was as a workman that Robert S. was great, his political views being at times rather narrow. Contrasting him with his great rival Brunel, it has been said that the ambition of the latter was to make a great work, that of the former to make a work which would *pay*. Robert S. inherited the kindly spirit and benevolent disposition of his father. He almost worshiped his father's memory, and was ever ready to attribute to him the chief merit of his own achievements.—See *Lives of the Engineers*, by S. Smiles, vol. iii. (Lond. 1862).

STEPPES, the distinctive name applied to those extensive plains which, with the occasional interpolation of low ranges of hills, stretch from the Dnieper across the south-east of European Russia, round the shores of the Caspian and Aral Seas, between the Altai and Ural chains, and occupy the low lands of Siberia. The word, which is of Russian origin, denotes primarily an uncultivated plain of great extent, and has been applied by geographers to the above-mentioned regions as expressive of their flat, semi-barren, treeless character. In spring and early summer, the steppes are clad with a thin covering of green herbage, become parched and barren under the scorching heat and drought of June, and in winter are hid beneath a thick covering of snow, which, raised in huge white thin clouds, and driven hither and thither by furious storms, brings destruction to every living creature within its sweep. The monotony of the steppe is as fatiguing to the traveler as is that of the sandy, arid desert: for hundreds of leagues his eye is compelled to endure the same unvarying level of scanty herbage, unbroken by tree or bush, and bounded by the utmost limits of the horizon; only in spring, while the vegetation is succulent and fitted for pasture, is the solitude broken here and there by herds of horses and cattle, and their mounted guardians. In autumn, when the tall herbage, withered by the heats of summer, has been rooted up and broken by violent winds, it becomes gathered and rolled together into enormous balls, sometimes of from nine to eleven yards in diameter. Here and there are tracts which offer some inducement to the agriculturist; such are the steppe east of the Dnieper, that between the Don and Volga—of inferior fertility, but rich in coal—and the steppes of South-western Siberia, especially those in the government of Tomsk, all of which have been partially colonized; but a very wide extent is hopelessly barren.

STERCULIA'CEÆ, a natural order of exogenous plants, closely allied to *Malvaceæ* and *Byttneriaceæ*, and consisting of large trees and shrubs, natives of warm climates. About 130 species are known. The flowers of some are irregular; and in some they are hermaphrodite, in others unisexual. Many species, particularly of the sub-order *Bombaceæ*, are trees of gigantic size, amongst which is the Baobab or *Adansonia* (q. v.) *digitata*. The bark of some species is very fibrous, so that it is made into ropes and coarse cloth. The light wood of *Ochroma lagopus* is used in the West Indies instead of cork. *Sterculia fœtida*, an Indian tree, with excessively fetid flowers, has pale wood, which is very durable, and susceptible of a high polish. Spars of this wood are called *Poon Spars*. The seeds of some species, as of the Silk-cotton (q. v.) trees, are surrounded with silky hairs. The seeds of all the species are oleaginous; those of some are eatable, as those of the CHICHA (*Sterculia chicha* and *S. lasiantha*) of Brazil, which

Chicha (*Sterculia chicha*):
a, branch with leaves and flowers; *b*, parts of fructification; *c*, pistil; *d*, transverse section of ovary.

are about the size of a pigeon's egg, and have a pleasant flavor. They are roasted before being eaten. The Cola (q. v.) Nut of Africa is the seed of a *Sterculia*. The whole order agrees with *Malvaceæ* in possessing mucilaginous and demulcent properties. The Gum Tragacanth (q. v.) of Senegal and Sierra Leone is produced by a *Sterculia*. The Durian (q. v.) is the fruit of a tree of this order.

STERE (Gr. *stereos*, solid), the name given to the unit of cubic measure in the French metrical system. It is a cubic *mètre* (q. v.), and equivalent to 35·3165818168 English cubic feet, or 1·3080215487 English cubic yards. The *decastère* is equal to 10 steres, and the *decistère* to the tenth part of a stere. This measure is much used for wood, especially firewood.

STERELMI'NTHA (Gr. *stereos*, solid, and *helmins*, an intestinal worm), a term suggested by Professor Owen, and generally adopted to signify those intestinal worms which have no true abdominal cavity, and which were called 'parenchymatous' by Cuvier. See CŒLELMINTHA.

STE'REOCHROMY, a process of wall-painting, invented by Professor J. N. von Fuchs, of Munich, professed to be superior to fresco-painting, inasmuch as it will admit of any part of the picture being retouched, as in the case of oil-paintings. It is also more durable being protected by a varnish from the effects of the atmosphere.

STE'REOSCOPE (Gr. *stereos*, solid, and *skopein*, to see), an optical instrument of modern invention, by means of which pictures of objects possessing three dimensions, are seen not as plane representations, but with an appearance of solidity or relief, as in ordinary vision of the objects themselves. The more recondite principles of the stereoscope, which are of high interest and importance in their bearing on the philosophy of perception, will be fully considered under VISION, BINOCULAR. The present article

will be limited to an historical sketch of its invention and subsequent developments, coupled with an exposition of the optical and mechanical details of its construction.

The essential principle of the stereoscope, the first conception of which by Professor Wheatstone, justly ranks as one of the most brilliant optical discoveries of the age, may be thus explained. It is an obvious fact that the eyes being separated by a certain interval of space, all solid objects so near to the observer as to be seen with a sensible convergence of the optic axes, necessarily form retinal pictures, differing as to their perspective projections for each eye. Singular to say, the true import of this plain fact was wholly unsuspected prior to the investigations of Professor Wheatstone, who, in his first paper on this subject, published in the *Philosophical Transactions* for 1838, clearly established the important conclusion, that this dissimilarity of the retinal images is made to subserve an important end in the use of our visual organs—that it is, in fact, the principal originating cause of our immediate perception of the solidity (or relief) of objects adjacent to the sight. The problem he set himself to investigate was: 'What would be the visual effect of simultaneously presenting to each eye, instead of the object itself, its projection on a plane surface as it appears to that eye?' and in order to bring this question to the test of experiment, he devised an instrument which he named the stereoscope, and which with certain additions more recently proposed by the same author, is shown in fig. 1.

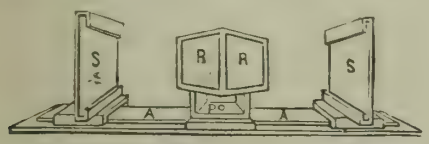

Fig. 1.

RR, two square mirrors about three inches in diameter, fixed vertically with their backs at a right angle with each other; SS, slides for the reception of the pictures, the *left*-hand picture being placed in the *right*-hand slide, and *vice versâ*, on account of the lateral inversion of their reflected images. SS are made to slide along the arms AA, so that their distance from RR may be varied at pleasure. SS also revolve each on a vertical axis, to admit of the variation of their angular position with reference to the arms AA. AA may also be moved in a horizontal plane, on the common pivot P.

The pictures being attached to the slides, the observer places himself with his nose close to, and immediately in front of, the vertical angle made by the reflectors, so that the view by each eye is limited to the rays reflected by its appropriate mirror; the pictures are then seen, as it were, behind the mirrors, and the eyes being made slightly to converge, either by an effort of the will, or by drawing the slides, SS, a little forward, the effect of either of which is to refer the reflected images to the same part of space, the observer sees no longer mere pictorial resemblances, but, to all appearance, the objects themselves, exquisitely modelled, occupying a certain extent of space, and standing forth with a substantiality of aspect truly wonderful. At the outset, the only stereoscopic pictures obtainable were the outlines of geometrical solid figures, which it was possible for a skilful artist to depict with perspective projections adapted for the right and left eye respectively; and the pictures so prepared excited the greatest interest and admiration. They, moreover, abundantly exemplified the truth and importance of the binocular principle, though the universality of its application to purposes of pictorial illustration only became apparent on the introduction and gradual improvement of the photographic arts. In 1849, Sir David Brewster originated that convenient, portable, and in all respects admirable form of the stereoscope which is now in general use over the whole civilized world. For this—the lenticular stereoscope—the pictures (taken, be it remembered, from two different points of view) are mounted side by side, on a piece of cardboard, and, being placed in the instrument, are viewed through semi-lenses, fixed at the distance apart of the two eyes.

To effect the displacement of the pictures, so that they shall be referred to the same part of space, which we have above defined to be an essential condition, Sir David Brewster most ingeniously availed himself of an opticle principle, which enabled him at the same time to fulfil several collateral ends of considerabfe importance. This principle may be described as follows: If an object be viewed through the center, or, more properly, along the axis, of a convex lens, it will be seen exactly in front of the eye; i. e., in a line with the eye, the center of the lens, and the actual place of the object. If now the lens be moved slightly to the left, the object will appear towards advance to the right; and, conversely, as the lens is moved towards the right, the object is displaced in the opposite direction. Let the lens be cut in half, transversely, and the two semi-circular pieces reversed as to their former position, i. e., placed side by side, and so that their thin edges shall be adjacent, while the two plane edges, formed by the section of the lens, are kept in mutual parallelism, and have their faces turned outwards, towards the left and right respectively: the right eye will now look through the left half of the lens, and *vice versâ*; and the two pictures, each placed opposite its appropriate eye, and in the principal focus of the eye-piece, will be seen not in their actual places, but in a position midway between the two.

The subsidiary purposes served by this arrangement are, that the pictures are magnified as well as caused to coalesce; and that the equality of the magnifying power of the eye-pieces (a result by no other means certainly attainable) is secured by the fact of their being cut from the same lens, the whole of which is thus advantageously and economically utilized. In too many of the instruments offered for sale, the conditions stated above are very imperfectly fulfilled; the parallelism of the two sectional planes of the semi-lenses, and their rectangularity with two imaginary planes joining their opposite ends respectively, are not maintained, and as a consequence, the coalescence of the pictures is effected, if at all, by a forced and more or less painful displacement of the eye-balls, entirely destructive of all pleasure in the use of the instrument. And it is important to recollect that this parallelism of the sides of the semi-lenses may be either actual or virtual; for to whatever shape they may be cut (and the circular form is the one most often adopted), the foregoing conditions are in no wise altered. The best lenticular form of the instrument with which we are acquainted, is the achromatic stereoscope devised by Messrs. Smith, Beck, and Beck, the well-known London opticians, which combines excellencies of a very varied character. Its construction is shown in fig. 2.

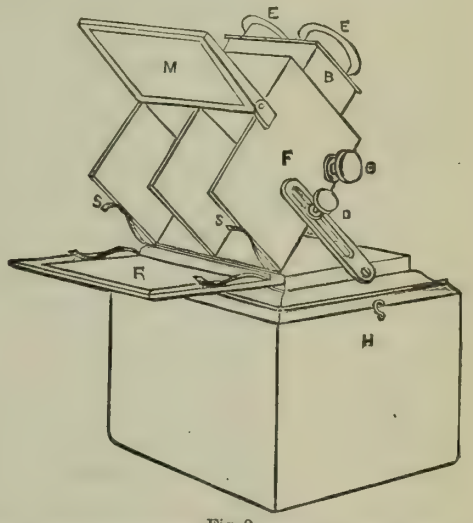

Fig. 2.

EE, the eye-pieces fitted to the sliding-box, B, which, by means of the milled head, C, attached to a rack-and-pinion movement, can be moved out or in for adjusting the focus. D, a slot and screw for fixing the body of the stereoscope, F, at any desired inclination; M, a mirror for reflecting light upon the picture, which is inserted between the springs, SS, and the woodwork of the stereoscope, and is thus firmly held. For viewing transparencies, the flap containing M is closed, and the picture illuminated by light reflected through it by the mirror R, the inclination of which is adjustible at pleasure; H is a box forming a convenient receptacle for the whole of the instrument.

It remains to speak of the pictures in their relation the one to the other as a stereoscopic pair. Evidently, exactly to reproduce the conditions of normal vision, they should be taken from points of view separated laterally by a space equal to the distance between the eyes, viz., about 2½ inches; and for all objects within narrow limits of distance this rule is observed. But taking a wider range, such as would include, for instance, an extensive architectural pile, photographers usually take their pictures from spots separated by a considerable interval; and the stereoscopic slides thus obtained, when viewed in the stereoscope, exhibit effects of solidity or relief of a very striking character. Inasmuch, however, as these effects are due to a gross exaggeration of the ordinary difference of perspective relatively to the two eyes, they to a like extent misrepresent the actual appearance of the scene; and it were to be wished that for all stereoscopic pairs alike, whether representative of near or of remote objects photographers would be content to adopt that exact relation of the two retinal pictures which subsists in ordinary binocular vision.

As to the mounting of the pictures it is of course highly important that they be placed exactly in the same line; it has further been pointed out by Mr. Claudet that, as the apparent solidity of the objects viewed in the stereoscope conflicts with the evident flatness of the cardboard mount, it is advantageous to adopt the following expedient. The pictures must be of the same size, but instead of having them identically the same as regards

the objects represented on each, let the left-hand picture include on its left-hand margin somewhat less than is found on the same margin of the right-hand picture; similarly, let its right-hand margin contain somewhat more than is found on the same margin of the right-hand picture: then will the view appear to extend well out of and beyond the cardboard, which forms, as it were, a framework around it. A moment's consideration will show that this ingenious arrangement does but reproduce the conditions which obtain whenever we look out upon a scene through a casement distant from us by a few feet. Availing himself of the libration of the moon, Mr. Warren De La Rue has obtained lunar stereoscopic photographs, which exhibit that body with a general appearance of rotundity, while the objects on her surface are seen in conspicuous relief. These effects are, however, evidently due to an exaggeration of the 'binocular parallax;' for by no human eyes, how near soever they might be placed to the lunar surface, could such a view be obtained. It is, as Sir John Herschel has remarked, as though the moon were seen with the eyes of a giant, placed thousands of miles apart.

Among the minor applications of the stereoscope, may be mentioned the STEREOMONOSCOPE and the STEREOTROPE, the former devised by Mr. Claudet, the latter by Mr. William Thomas Shaw; and severally described by them in the *Proceedings of the Royal Society* of June 1857, April 1858, and January 1861. In the stereomonoscope, the two pictures of a stereoscopic pair are projected, by means of lenses, on to the posterior surface of a piece of ground glass, one upon the other, or so that they occupy the same place; when the observer, looking from the opposite side of the glass, sees them not as a confused mixture of two pictures, but as a single stereoscopic representation, possessing the usual attributes of solidity or relief. The stereotrope consists in an application of the principle of the stereoscope to that class of instruments variously termed thaumatropes, phenakistoscopes, &c., which depend for their results on 'persistence of vision.' In these instruments, as is well known, an object represented on a revolving disc in the successive positions it assumes in performing a given evolution, is seen to execute the movement so delineated; in the stereotrope, the effect of solidity is superadded, so that the object is seen as if in motion, and with an appearance of relief as in nature. A highly ingenious application of the principle of the stereoscope to portraiture has been described by Mr. Henry Swann in the *Report of the British Association* for 1863. In this arrangement, the portrait is seen as a solid bust embedded in a cube of crystal. A form of the reflecting stereoscope, in which the planes of reflection are vertical, has been proposed by Mr. Walter Hardie.

But by far the most important application of the stereoscopic principle, is its realization in the binocular microscope of Mr. Wenham, the advantages of which over the monocular form of that instrument are increasingly appreciated by microscopists. In this, the right and left eye pictures, respectively, are thus obtained. Immediately behind the object-glass, a small and peculiarly shaped prism is placed in such a position, that it shall receive the whole of the rays coming through the right half of the lens. These rays, after being twice reflected within the body of the prism, finally emerge at such an angle to their original direction, that they cross the undiverted pencil of rays transmitted by the other half of the lens, and are then received into a second tube, which, being inclined to the first or main tube at an appropriate angle, conveys them to the left eye; while the other complement of rays pursues an undeviating course to the right eye. Each of the two tubes is fitted with the usual eye-pieces; and object-glasses of all but the highest powers may be used with pleasure and advantage. For a fuller explanation, see the original paper by Mr. Wenham in the *Transactions of the Microscopic Society*, new series, vol. ix., page 15.

STE'REOTYPING (Gr. *stereos*, fixed, solid), the art of fabricating metal plates resembling pages of type, from which impressions may be taken as in ordinary letterpress-printing. The plates, which are composed of type-metal, are about three-sixteenths of an inch thick, perfectly smooth on the back, and having a face exactly resembling a page of movable type. To yield an impression, the plates are fastened by a temporary arrangement to blocks of wood—plate and block together being the height of a type, or one inch. Stereotyping is not employed where only a definite and moderate number of impressions of any work are required. Its chief value consists in its availableness for future impressions contingent on the renewed demand for copies; but it is also of importance in duplicating the means of taking large impressions quickly. Considering the small quantity of metal employed in fabricating a stereotype plate, printers are enabled to secure and store up forms of type, so to speak, at a comparatively small outlay, and have at all times the means ready at hand to produce fresh editions without the trouble or cost of setting a single letter.

As in the case of many valuable inventions, there has been not a little discussion as to who was the discoverer of the art of stereotyping. By some it has been ascribed to Van der Mey, a Dutch printer, who early in the 18th c. executed editions of the Bible from forms of fixed type. Van der Mey's process, however, was not stereotyping in the proper sense of the word; for it consisted in nothing more than soldering together all the types in a page in order to fix them permanently. There can be no doubt that the inventor of stereotyping was William Ged, a goldsmith in Edinburgh, who made the discovery about 1725. In 1727, he entered into a contract with a person to prosecute the business of stereotyping; but this person, who had little means, becoming intimidated, the contract was relinquished. In 1729, Ged entered into a partnership for the same object with William Fenner, a London stationer. Afterwards, John James, an architect, Thomas James, a typefounder, and James Ged, son of the inventor, joined the partnership. By this association, certain Bibles and Prayer-books were stereotyped for the university of Cambridge about 1731. Ged's success was so far complete, but his prospects were blighted by ill-treatment from his partners, as well as by the misconduct of the pressmen employed to print from his plates, which they maliciously damaged and rendered imperfect. The university appears to have at length abandoned the use of the plates, which were sent to Caslon's letter-foundry in London to be melted. A few of these plates escaped the crucible, and from two of them, being pages of the Book of Common Prayer, impressions are given in Hansard's *Typographia*, Part II. (1825).

Ged's partnership was broken up in 1738, and full of disappointment he returned to Edinburgh. There, he prosecuted his art, and was able to execute several editions of Sallust, of a small size, for the use of schools. Copies of these editions still exist. The earliest which we have seen purports to be printed in 1739, and bears an imprint in Latin which may be translated as follows: 'Not executed by movable types, but by tablets of fused metal.' The printing is as neatly executed as that of any volume at the period. This Sallust of 1739, as we apprehend, was the first book correctly printed from stereotype plates. To add to the cares of William Ged, his son James engaged in the Jacobite insurrection of 1745, and was taken prisoner, and condemned; his life, however, was spared on account of his father's useful invention, and he proceeded to Jamaica, where William, his brother, was already settled. William Ged, the inventor of stereotyping, died at Edinburgh, October 19, 1749, in very indifferent circumstances.

The art of stereotyping has undergone little change since its discovery by Ged. The process of fabricating plates is very simple. The page of type being set, corrected, cleaned, and fixed in a frame, is laid on a smooth iron table, face upward; a little fine oil is brushed over it, to prevent the liquid stucco from adhering; the stucco to the consistency of cream is now poured over the face of the page, and straightened over it in the process of hardening; when hardened, the cake of stucco is lifted off, and is seen to be a perfect mould of the types. The cake is now baked in an oven, and then placed in an iron pan; the pan, which has inlets at the upper side, is plunged into molten metal, which soon runs into the mould; being lifted out and cooled, the pan is opened and found to contain a plate resembling the page of type; the mould is broken and of no further use. When removed from the pan, the plate is rough, and needs to be trimmed for working; for this purpose, it passes through the hands of artisans, who prepare it for the press. Should any particular letter be defective, it is dug out, and a corresponding type inserted; the end of which type is cut off at the back of the plate by a soldering bolt. In preparing plates for press, nothing is more important than giving a high degree of level smoothness to the back, and to effect this certain planing and smoothing operations are adopted. Such is the old and well-known *stucco* process of stereotyping.

Latterly, there have been divers improvements as regards the shape of the pans, in order to facilitate the fabrication of several plates at once, but the principle is in all cases the same. After the stereotyping is finished, the types are distributed. In some printing-offices, all work whatsoever is executed from plates, and types are employed only to produce moulds. This however, does not save types from deterioration; in cleaning them with brushes and oiling them for the stucco, their finer parts become in no long time rounded off. As regards impressions from stereotype plates, the work is seldom so sharp and fine as from pages of movable letter; but it answers every required purpose in a large variety of cases. Plates properly manufactured, stored, and mended when necessary, will last for repeated impressions to the extent of hundreds of thousands over a long series of years. The stock of plates in some establishments is accordingly large, and represents a considerable sunk capital. When no longer required, the plates are melted down as material for fresh castings.

The *paper* process of sterotyping was invented some years ago on the continent, but has been since perfected in the *Times* office, where it was adopted for duplicating newspaper forms. See TIMES. A uniform sheet of soft and damp matter is formed by gumming together, first a sheet of thin yet very tough tissue paper; second, a sheet of loose and bibulous white paper; and

third, a sheet of fine-grained and tough brown paper. The smooth and white side of the sheet, still soft and moist, is placed on the types. Both are then put in a press. A roller passes under the form, and presses it up against the paper, so as to receive the impression of the types and convert it into a mould. The dents made by the types rise on the outside of the paper, so that any spot where the paper has not sunk into the spaces between the types is at once detected. Such spots generally occur, and are removed by the paper being driven in between the types by blows of a hard brush. The dents made by the types, we have said, are represented by elevations on the outside of the sheet, and the interstices are represented by corresponding hollows. The latter are filled up at this stage by a thin coating of stucco laid on by a brush. The mould is then carefully removed dried, and placed in a shallow box of metal placed upright. The smooth or stucco side of the mould is pushed against the back of the box. The lid is then closed very tightly, leaving only an opening at the top. Through this opening molten metal is poured, and a plate is thus formed, one side of which, of course, is a cast from the mould. It contains elevations at places where there are wide spaces between the types, and these it is necessary to remove with the chisel. In other respects the plate is an exact copy of the form. The great advantage of this mode of stereotyping is its rapidity.

Plates from stucco could scarcely be produced and ready for press in less than six hours; plates from paper can be produced and laid on the machine in less than one hour. Indeed, in the *Times* office, where the process has been carried to great perfection, the plates are now produced in seven minutes. By the paper process, plates are produced every morning for the London newspapers and others of which vast impressions are required. The forms of types themselves are no longer used, a number of plates being produced corresponding to the number of machines employed (see TIMES), and all the copies of the paper are printed from them. A very great saving in the cost of types is thus effected. It was necessary to renew the fount every few months in the *Times* office, when that paper was printed in the usual way. Since the introduction of the new process, the expense of the production of that great newspaper has been to a considerable degree kept in check. The types last as many years as they did months when printed from.

To accommodate printing machines on which the forms need to be fixed in a cylinder, the paper moulds are placed in pans or boxes which are of the required shape. The moulds are then bent with their backs outwards, and the molten metal is poured between the concave mould and convex lid. The plates are generally cast in four segments, which screwed together form a cylinder. They are adjusted to the printing press by a planing machine, which cuts their inner surface to the exact convexity of the cylinder. To this duplication there is of course no limit; sets of plates can be produced to any required number. As copies of old newspapers are not wanted, the plates are melted down as soon as the operations of the day are over. Even when books are printed from movable types, it may serve a good purpose to take paper moulds from them before distribution; for the moulds, on being dried, can be laid aside and be afterwards employed for fabricating plates should a new impression be wanted. The author of a book, for example, could at a most insignificant addition to the expense of typography, possess himself of a set of paper moulds of his work, to be used if necessary at some future period, in order to save the composition for a new edition. W. G.

STE'RLET. See STURGEON.

STE'RLING, an epithet generally applied to the money of the United Kingdom. The original standard of money was weight, and among the Anglo-Saxon and Teutonic nations the basis of weight was in early times supplied by the wheat-corn. Charlemagne superseded the earlier systems by a new coinage, in which a pound of 12 ounces became the money-weight, each pound being divided into 20 solidi, and each solidus into 12 denarii of the weight of 32 wheat-corns. The older *silfer* or scruple of 24 wheat-corns being superseded by the penny of 32 wheat-corns, the term sterling seems to have been applied to the latter, in consequence of its being in use among the Ripuarian or Austrasian Franks, sometimes called the *Esterlings*, while the old scruple continued to be used by the Northmen. In England, where the change was early introduced, the word sterling came in the course of time to indicate the fineness or standard of the silver; and nearly the same standard, consisting of 11 oz. 2 dwt. of pure silver, and 18 dwt. of alloy to the pound troy, or $\frac{1}{22}$dwt., seems to have subsisted from the 12th c. downwards. The superiority of the English standard silver to all other currency has been generally acknowledged over Europe; and hence the adjective sterling has become a synonym for pure and genuine.

STE'RNBERG, a town of Austria, in Moravia, 12 miles N.-N.-E. of Olmütz. Pop. (1880) 14,243. It is the chief seat of the Moravian cotton manufactures, and has also not unimportant manufactures of linen, hosiery, and liqueurs. The cotton and linen goods made at S., and in the vicinity, are known as *S. wares*.

STERNE LAURENCE, though of English descent and parentage, was born at Clonmel, in Ireland, on 24th November 1713. In that country also, in some intermittent way, a good deal of his boyhood was passed, with possibly some effect in developing that oddity and whimsical exuberance long after to find vent in his writings. His father was of a good Yorkshire family, and as lieutenant in a marching regiment led a wandering and unsettled life. When about ten years old, the boy was consigned to the care of his kinsman, Mr. Sterne of Elvington, in Yorkshire, by him put to school near Halifax, and thence, on his proving himself a lad of parts, transferred in 1733, to Jesus College, Cambridge, where, in 1736 and 1740 respectively, he took the degrees of Bachelor and Master of Arts. He was educated for the church, and on his leaving the university, his uncle, the Rev. Jaques Sterne, an ecclesiastical dignitary of some magnitude, procured for him the living of Sutton in Yorkshire. With this relative he afterwards quarrelled, but not before another appointment had been secured him as Prebendary of York cathedral. In 1741, he was married to a lady whom he met in York, and soon after, through the influence of a friend of his wife, he was presented to the additional living of Stillington. For nearly 20 years he lived at Sutton unheard of.

That his devotion to his clerical duties was great, is more than can be supposed from what we know of his character; and we can readily believe the 'books, painting, fiddling, and shooting,' which he tells us were his choice recreations, formed pretty much the business of his life. Up to the year 1759, in which the first two volumes of his *Tristram Shandy* appeared, he had published only two sermons, which, according to his own statement, 'found neither purchasers nor readers.' *Tristram Shandy*, which, though published without his name, was from the first known to be his, had instant and immense success, and S., on going up to London, found himself the literary lion of the day. In 1761, two more volumes of it appeared, followed by vols. 5 and 6 in 1762, vols. 7 and 8 in 1765, and in 1767 by the 9th and last. During this period he also issued 4 vols. of sermons, and the *Sentimental Journey*, published in the beginning of 1768, completes the list of his works. He died on 18th March of that year, his health having been much impaired for some considerable time.

From the time of his becoming famous his parishioners saw of S. but little. He lived mostly either on the continent or in London, where his literary celebrity made him welcome in the best circles. Always an easy, mercurial kind of mortal, he now led somewhat a gay and dissipated life, rather modelled on the Epicurean maxim of enjoying the present hour, than on those more serious precepts he had been wont to enforce from the pulpit. But except that he does not seem to have been excessively devoted to his own wife—she and her daughter being in these pleasant years but little with him—and was a little of a sentimental Lothario in respect of the wives of other people, no very great harm is known of him. He is said, despite of the exquisite sentiment which abounds in his writings, to have been really heartless and unfeeling; and the sneer of Walpole, that he could snivel over a dead ass, to the neglect of his live mother, is familiar to almost every one. It is in fairness, however, to be said that the implied slander rests on no distinct basis of evidence.

Whatever question may be made of the worth of S. as a man, there can be none of his genius as a writer. *Tristram Shandy*, his chief work, must live as long as the language, were it only in virtue of the three characters of Old Shandy, Uncle Toby, and Trim, the most perfect and exquisite, perhaps, in the whole range of British fiction. These are genuine creations, at once fantastic and real, in which the subtlest reconcilement is effected between the sportive exuberance of fancy and the sober outlines of truth. Otherwise there is a good deal in the work which needs excuse; in particular, a most wilful and gratuitous indecency almost without a parallel, and a constant trick of lawless and whimsical digression, to the endless incalculable frivolities of which even the inimitable grace, ease, and tricksy flexibility of the style can with difficulty reconcile the reader. The humor of S. is notwithstanding the most subtle, airy, delicate, and tender to be found in our literature; and in many passages he shows himself master of a pathos equally exquisite and refined. See also Traill's *Sterne* (1882). Though against the charge of unclerical levity, at once in his writings and his life, it is impossible to defend S., except as the laxer *morale* of his time may afford some slight palliation of it, candid investigation suggests a considerably more kindly view of his character than that which used to be current. Traill's short life of S. (1882) stands midway between Fitzgerald's apology (*Life*, 2 vols., 1864) and Thackeray's unsparing attack.

STERNHOLD, THOMAS, one of the authors of the English version of psalms formerly attached to the Book of Common Prayer, was a native of Hampshire, and born towards the close of the 15th century. He held the office of Groom of the Robes to Henry VIII. and Edward VI., and died in 1549. At the Refor-

mation period, when the practice of singing metrical psalms—first introduced by Clement Marot among the gay courtiers of Francis I.—came to be taken up by the Reformers, S. undertook to render the whole book of Psalms into English verse. He only lived to complete twenty-one psalms; and his version was published after his death under the title of *All such Psalm of David as Thomas Sternhold did in his Lyfe drawe into English metre* (Lond. 1549). S.'s labors were completed by John Hopkins and William Whittinghame, and first annexed to the Book of Common Prayer with the music attached, as *The Whole Booke of Psalmes collected into English metre by Thomas Sternhold, John Hopkins, and others; compared with the Ebrue, with notes to sing withal.* S. and Hopkins's psalms are very literal, but somewhat coarse and homely in phraseology. They were used in the church service of England till superseded by the version of Tate and Brady, which appeared in 1698. They were also in use in Scotland down to the middle of the 17th century.

STE'RNIDÆ. See TERN.

STE'RNUTATORIES, are agents which cause sneezing. The most common are the different kinds of snuffs, but other substances are known which produce a more powerful and prolonged action on the nasal mucous membrane. They have been employed in medicine with various objects; as, for example, to restore suspended respiration in case of fainting, to dislodge foreign bodies from the nasal passages or even the windpipe, to avert or check histerical attacks, and to terminate prolonged fits of hiccup. They are scarcely ever used at the present day.

Stethoscope.

STE'THOSCOPE, THE (Gr. *stethos*, the chest, and *skopeo*, I look into), is an instrument invented by Laennec for examining the sounds of the chest. Its form will be best understood by the figure, which represents the section reduced to half the natural diameter, or one eighth of the actual size. The upper part is the chest end, the lower the ear-piece. The most convenient measurements are—length, 7 inches; diameter of the ear-piece, 3 inches; circumference of shaft, 1¼ inch, and diameter of chest end, 1¼ inch. The main object of the stethoscope being to circumscribe and localize the sounds which it transmits, the chest end should be small, in order to determine the exact seat of the greatest intensity of sound. To ascertain this, the instrument should be moved right and left, up and down, till its end is on the exact spot from which the abnormal sound for which we are searching—or, it may be, the absence of sound—proceeds.

In the construction of the stethoscope, the following points should be attended to: 1. It should be composed of a material which allows the least amount of sound to be lost, and which least of all modifies or prevents the sound. A porous wood, such as cedar or deal, answers these conditions best, a dense wood, like ebony, having a tendency to modify the sound; 2. It should be of one piece of wood, and not, for example, part ivory and part cedar; 3. The ear-piece should be large and flat to secure perfect apposition and occlusion, and the chest end should be narrow and smoothly rounded over the edge. The various sounds heard through the stethoscope are described in the articles RESPIRATORY SOUNDS, PNEUMONIA, &c.

STETTI'N, an ancient town of Prussia, capital of the province of Pomerania (*Pommern*), and, after Danzig, the most important sea-port in the kingdom, is situated on the left bank of the Oder, where it flows into the Stettiner-Haff 83 miles north-east of Berlin, with which it is connected by railway. The entire population of this town in 1880 was 91,756. Across the river, which is here from 12 to 16 feet deep, lies the suburb of Lastadie, connected with S. proper by means of two bridges. Outside the fortifications lie the suburbs of Upper and Lower Wieck and Tornei. The site of the town is hilly, and in consequence the streets are uneven, but the houses are good and the environs very pleasant. The principal buildings are the castle or fortress, the government house, the 'county buildings' with a valuable library, the exchange, and theater. The chief manufactures are silks, leather, sail-cloth, cottons, &c. There is also a large anchor foundry, where all the anchors for Prussian ships are forged.

Ship-building and the manufacture of machinery give employment to great numbers; and the commerce of the city is extensive and increasing. S. is the port whence the products of Silesia, both natural and artificial, are mainly shipped to other countries. Corn, wood, and brandy are the principal articles of export. The value of the annual imports into S. is about £10,000; of the exports about half that amount. In the course of a year about 1700 ships enter the port from foreign countries, of near 200,000 tons burden. S. was formerly a fortress of the first rank.—The *Stettiner-Haff* is formed by an expansion of the river Oder, north of the town of S., and is nearly quite shut in from the Baltic, having communication with the sea only by three narrow straits, the most important of which is the Swine. See SWINEMUNDE. It has an area of 200 sq. m., and a depth of from 12 to 18 feet.

S., the ancient *Sedinum*, later *Stettinum*, is of Slavic origin, became a flourishing commercial town in the middle ages, joined the Hansa, and was repeatedly the residence of the Dukes of Pomerania.

STEUBEN, FREDERIC WILLIAM AUGUSTUS, BARON, a general of the American revolutionary army, was born at Magdeburg, Prussia, November 15, 1730, educated at the Jesuits' College of Niesse and Breslau; and at the age of 14 served as a volunteer under his father at the siege of Prague. In 1747 he was appointed cadet of infantry, and in 1758 had risen to the rank of adjutant-general. He was wounded in the battle of Kunersdorf, and in 1761 was conducted as a prisoner of war to St. Petersburg, but was shortly after released. The following year he was appointed adjutant-general on the staff of the Prussian king, effected important reforms in the quartermaster's department, and superintended an academy of young officers selected for special military instruction. At the close of the Seven Years' War, he traveled in Europe, and was appointed Grand Marshal and General of the Guard of the Prince of Hohenzollern-Hechingen. Being on a visit to Paris in 1777, where the cause of the American rebellion was favored by the government, he was invited by Count St. Germain to go to America. He arrived at Portsmouth, Virginia, December 1, 1777, and offered his services to General Washington, which were joyfully accepted; and he joined the army, then in the most deplorable condition, at Valley Forge.

He was appointed inspector-general, prepared a manual of tactics for the army, remodelled its organization, and improved its discipline. He was one of the officers who composed the court-martial at the trial of Major André. In the campaign of 1780 he had a command in Virginia, and was on the staff of General Lafayette at the siege of Yorktown. As generous in character as he was capable as an officer, he spent his whole fortune in clothing his men, and gave his last dollar to his soldiers. Congress made tardy reparation, and in 1790 voted him an annuity of 2500 dollars, and a township of land in the state of New York, both of which he divided with his fellow-officers. He died on his estate near Utica, New York, November 28, 1794. See Sparks's *American Biography*, and a Life by Fredrich Kapp (New York, 1860).

STEVENSON, ROBERT, a Scotch engineer, was born at Glasgow, 8th June, 1772. His father, who was a merchant connected with the West India trade, died during his infancy; and his mother having (1786) married Mr. Thomas Smith, the first engineer of the Light house Board, young S. was led to devote himself to the study of engineering, in which his progress was so rapid that in 1791 he was intrusted by Mr. Smith with the erection of a light-house on little Cumbrae. In 1796, he succeeded his father-in-law as engineer and inspector of light houses; and during his 47 years' tenure of that office, he planned and constructed no fewer than 23 light-houses round the Scottish coast; employing the catoptric system of illumination, and his valuable invention of 'intermittent' and 'flashing' lights.

The most remarkable of these erections was that on the Bell Rock (q. v.), for which he had been sketching plans for some time, when the wreck of the *York*, a 74-gun ship, on this reef drew general attention to the same subject. The enterprise was quite unprecedented in light-house engineering, for in the only instance at all analogous—the Eddystone Light-house—the rock was barely submerged at flood, while the Bell Rock was never uncovered except at very low ebb tides. In 1814, S., was accompanied in his tour of inspection by Sir Walter Scott, and while the former was projecting another light-house on the Skerryvore (q. v.), near Tiree, the latter was doubtless laying up ample materials for those minute descriptions of the west coast of Scotland and its islands which were afterwards embodied in the *Lord of the Isles*. S. was also in great request as a consulting engineer in the matter of roads, bridges, harbors, canals, and railways, introduced many improvements in their construction, and occasionally co-operated with Rennie, Telford, and others. He died in Edinburgh, July 12, 1850. Like most eminent practical men, S. has left few literary remains; these being merely four volumes of professional printed reports, a large work on the Bell Rock Light-house, some articles in the *Encyclopædia Britannica* and in the *Edinburgh Encyclopædia*, and a series of letters on the engineering works of the Netherlands in the *Scots Magazine* (1817). See his *Life* by his son, David Stevenson, C.E. (1878).

STE'VENSTON, a town of Scotland, county of Ayr, is a station on the Ardrossan and Saltcoats branch of the Glasgow and Ayr Railway, and is situated about three miles east of Ardrossan. Pop. (1881) 3556. S. consists mainly of one low, straggling, uneven, and narrow street, about half a mile in length; but the parish church is finely placed on a slight eminence, which commands a splendid view of the Arran Hills and the lower scenery

of the Firth of Clyde. Cotton-weaving used to be the chief industry of the place, but its prosperity now depends almost exclusively on the collieries and ironworks in its vicinity.

STEWARD OF ENGLAND, LORD HIGH, one of the great officers of state, and anciently the first officer of the crown in England. The dignity was in early times hereditary. From Hugh Grentmesnell, Lord Steward in the time of Henry II., it passed by the marriage of his daughter and co-heir to the family of De Bellomont, Earls of Leicester, and thence also by marriage to the Montforts, Earls of Leicester. On the death and attainder of Simon de Montfort, Earl of Leicester, in 1265, the office, reverting to the crown, was granted with the earldom of Leicester to Edmund, younger son of Henry III., and continued annexed to the earldoms of Lancaster and Leicester, till absorbed into the royal dignity on the accession of Henry IV. Since that time, there has been no permanent Lord Steward, but the office is temporarily revived when occasion requires, a Lord Steward being appointed under the Great Seal *pro hac vice* at a coronation, or the trial of a peer (see PARLIAMENT). When the proceedings are at an end, the Lord Steward terminates his commission by breaking his wand of office.

STEWARD OF THE HOUSEHOLD, LORD, an officer of the royal household in England, of great antiquity, originally designated the Lord Great Master of the Household. He is the head of the ancient court called the *Board of Green Cloth*, and as such has the control of all the officers and servants of the household, except those belonging to the Chapel, the Chamber, and the Stable. The other members of the Board of Green Cloth are the treasurer and the comptroller, over whom, as well as the Master of the Household, the Lord Steward's authority extends. That court, had, by 3 Hen. VII. c. 14, and 33 Hen. VIII. c. 12, authority to try and punish all treasons, misprisions, murders, manslaughters, bloodsheds, &c. in the royal palace, and within the verge of the court. But this jurisdiction, which had long fallen into disuse, was in part repealed by 9 Geo. IV. c. 31, and altogether abolished by 12 and 13 Vict. c. 101; and the functions of the Board of Green Cloth are now confined to the supervision of the household expenses and accounts, the purveyance of the provisions and their payment, and the good government of the servants of the household. The Lord Steward selects all the subordinate officers and servants, except those connected with the royal stables; he also appoints the Queen's tradesmen. He is always sworn a member of the Privy Council, and has precedence of all peers of his own degree. He has no formal grant of office, but receives his charge from the sovereign in person, who, delivering to him a white wand as his staff of office, says: '*Seneschal, tenez le bâton de notre maison.*' He holds his appointment during pleasure, and his tenure depends upon the political party to which he belongs. The salary of the office is £2000.

STEWARD or HIGH STEWARD OF SCOTLAND, an office of high dignity and power under the Scottish crown during the 12th, 13th, and 14th centuries (called in Latin *dapifer* or *seneschallus*). The High Steward not only was chief of the household, but collected and managed the crown revenues, and possessed the privilege of holding the first place in the army next to the king in battle. The office was early in the 12th c. conferred by David I. on Walter, second son of Alan, Lord of Oswestry, along with extensive territorial possessions, comprehending among others the barony of Renfrew; and the dignity of steward became hereditary in his family, who in virtue of their office assumed the surname of Stewart. The accession of Robert, the seventh High Steward, to the throne, as Robert II., merged the seneschalship in the crown; but the estates of the stewards afterwards became the appanage of the king's eldest son, and by act of the Scottish Parliament of 1469, the titles of Prince and High Steward of Scotland, Duke of Rothesay, Earl of Carrick, Baron of Renfrew, and Lord of the Isles, were vested in the eldest son and heir apparent of the crown of Scotland for ever. 'Great Steward of Scotland' has thus become one of the titles of the Prince of Wales. See STEWART, FAMILY OF.

STEWART, THE FAMILY OF. The origin of the Stewarts, long obscured by myth, was rediscovered in the beginning of the present century by the indefatigable antiquary, George Chalmers. Alan, son of Flahald, a Norman, accompanied the Conqueror into England, and obtained by his gift the lands and castle of Oswestry in Shropshire. His eldest son, William, remaining in England, became the ancestor of the Fitzalans, Earls of Arundel, from whom the Duke of Norfolk inherits that earldom through an heiress. The second son, Walter, passing into Scotland in the service of David I., had large territorial possessions conferred on him by that monarch, along with the dignity of Steward of Scotland, which became hereditary in his family, and was assumed by his descendants as a surname; some branches of the House, when spelling began to be considered, modifying the orthography to Steuart, or the French form Stuart. The fess chequy adopted as the arms of the family is emblematical of the chequer of the Steward's board. The connection between the Stewarts and Fitzalans was shown by Mr. Chalmers to have been well known and acknowledged as late as 1336, when Richard Fitzalan, Earl of Arundel, sold the Stewardship of Scotland to his sovereign, Ed. III., and Edward Baliol, as king of Scotland, ratified the transaction; the sale being a political fiction, founded on a supposed forfeiture of the Scottish branch of the family, by which the hereditary office reverted to the English branch.

The lands conferred on Walter the Steward by David I. included the barony, or what is now the county, of Renfrew, which became the chief patrimony of the family, as well as Innerwick, Hassendean, and other large estates in Teviotdale and Lauderdale. For seven generations the stewardship continued to descend without a break from father to son. Walter, the third, and grandson of the first Steward, held, in addition, the office of Justiciary of Scotland, and was one of the two ambassadors sent to conduct Marie de Couci, second wife of King Alexander II., to her adopted country. His third son, Walter, called Balloch, by his marriage with the younger daughter of Maurice, Earl of Menteith—the lady's elder sister having been banished and her rights forfeited—got the earldom of Menteith, and was ancestor of a line of earls and countesses of Menteith, of whom the Countess Margaret carried the earldom to her husband, Robert, Duke of Albany, son of King Robert II. Alexander, fourth Steward, was regent of Scotland in Alexander III.'s minority; he commanded at the battle of Largs in 1263, when the Scotch army obtained a signal victory over Haco of Norway; and invading the Isle of Man, annexed it to the Scottish crown. From his second son, Sir John Stewart, who married the heiress of Bonkyl, sprung various important branches of the family, including the Stewarts of Darnley, Lennox, and Aubigné. James, the fifth Steward, was one of the six regents of Scotland after the death of Alexander III.

Walter, the sixth Steward, occupies a conspicuous place among Bruce's companions-in-arms. When but a youth, he did considerable service as one of the principal leaders at Bannockburn, and, four years later, increased the promise of his fame by his successfull defence of Berwick against Edward II. in person. His marriage with Marjory, daughter of Robert Bruce, eventually brought the crown of Scotland to his family. He died at the age of 33, much lamented throughout Scotland. His son by Marjory Bruce, Robert, seventh High Steward, was regent from 1338 to 1341, and afterwards during the captivity of his uncle, David II., from 1346 to 1357; and in the midst of events which threatened a total overthrow to the liberties of Scotland, he exerted himself with zeal and energy in their defence, and was the main instrument in defeating the intrigues of David II. and Edward III. to place an English prince on the throne. On the death of David II. in 1371, he ascended the throne as Robert II., and died in 1390. He was twice married; first to Elizabeth, daughter of Sir William Mure of Rowallan, and afterwards to Euphemia, Countess of Moray, daughter of Hugh, Earl of Ross, and had issue by both unions. In consequence of Elizabeth Mure being related to him within the prohibited degrees, he obtained a dispensation for the marriage from Pope Clement VI. in 1347, in which those children who had already been born, as well as those to be born of that connection, were legitimated; and the succession to the crown was further regulated by parliament.

In later times, when the true history of these proceedings was lost or mystified, the descendants of Robert II.'s first marriage came to be branded with the suspicion of illegitimacy, while those of the second marriage were in the habit of boasting of their preferable claim to the throne; and the dispensation setting the question at rest was only discovered in the Vatican in 1789 by Andrew Stuart of Castlemilk. Of the children by the first marriage, the third son, Robert, Duke of Albany, and his issue are separately noticed below. The fourth son, Sir Alexander Stewart, who got the earldom of Buchan on the forfeiture of the Comyns, ruled over the northern part of Scotland with little less than regal authority, and his savage and ferocious character obtained for him the appellation of the 'Wolf of Badenoch.' He had no lawful issue, but several natural sons, one of whom stormed the castle of Kildrummy, the residence of the Countess of Mar, forcibly wedded that lady, and possessed himself of the earldom; and others were progenitors of the branches of the family known as the Athole Stewarts, of whom the principal were the Stewarts of Garth. For the subsequent history of the royal family, see articles ROBERT II. and III.; JAMES I., II., III., IV., V.; MARY, QUEEN OF SCOTS; JAMES I. (of England); CHARLES I. and II.; JAMES II.; WILLIAM AND MARY; and ANNE.

James II. (of England) was twice married, first to Lady Anne Hyde, daughter of Lord Chancellor Hyde; and secondly, to Mary Beatrice, daughter of the Duke of Modena. By the first marriage he had Mary, queen of William III., and Anne, who succeeded to the throne, neither of whom left issue; and by the second, James, Prince of Wales, born in 1688, known as the Chevalier St. George, or the elder Pretender. Prince James, who was born but a few months before his father's abdication, was commonly but ground-

lessly supposed to be a supposititious child, and was involved in his father's exclusion from the crown. In 1715, the party who supported him, known in history as the Jacobites, endeavored to procure him the throne by force of arms. In Scotland, the Earl of Mar, with about 5000 men, engaged the royal forces under the Duke of Argyll at Sheriffmuir: it was a drawn battle, but the result was a delay as fatal as a defeat. In England, the rising was headed by the Earl of Derwentwater, and ended by the unconditional surrender of the insurgents at Preston, when Lords Derwentwater and Kenmure were beheaded, and other persons of note executed and attainted. James escaped to France; and for the rest of his life resided in obscurity principally at Rome, where he died in 1766. In 1719, he married one of the wealthiest heiresses in Europe, Maria Clementina Sobieski, grand-daughter of John Sobieski, king of Poland, and by her had two sons, Charles Edward Lewis Casimir, born 1720, known as the young pretender (see STUART CHARLES EDWARD), and Henry Benedict Maria Clement, Cardinal York, born 1725.

Henry Benedict, second son of the Chevalier St. George, went to France in 1745 to head an army assembled at Dunkirk for the invasion of England, but the news of the defeat of Culloden put an end to his plan. He then returned to Rome, took orders, and was advanced to the purple by Benedict XIV. in 1747. During his brother's life, he was known as Cardinal York; but after his death he assumed the regal style as Henry IX., king of England. His various bishoprics and rich church livings enabled him for long to live in great splendor; but the expulsion of Pius VI. from Rome, and other events of the Revolution, drove him to Venice, aged and infirm, stripped of his means, and reduced to absolute poverty. His deplorable situation becoming known to the British court, George III. settled on him an annuity of £4000, which the cardinal accepted with gratitude, and enjoyed during the remainder of his life. He died in 1807, at the age of 82, the last surviving descendant of James II.

Next to the exiled Stewarts in representation of the royal house as heir-of-line came the descendants of Henrietta Maria, daughter of Charles I., who was married to Philippe, Duke of Orleans, brother of Louis XIV. of France. This princess had two daughters, of whom the elder, Mary, was queen to Charles II. of Spain, but died childless; the younger, Anna Maria, married Victor-Amadeus, Duke of Savoy and king of Sardinia, and was mother to Charles-Emmanuel III., king of Sardinia, and grandmother to Victor-Amadeus III., king of Sardinia. Victor-Amadeus had three sons who successively occupied the Sardinian throne as Charles-Emmanuel IV., Victor-Emmanuel I., and Charles-Felix, and a daughter who married Charles X. of France, and was mother of Henri, Duc de Bordeaux, present representative of the French Bourbons. Victor-Emmanuel and Charles-Felix left daughters only; and the present senior co-representative as heir-of-line of the House of Stewart, as well as that of Tudor, is Maria Teresa, wife of Prince Louis of Bavaria and only child of the younger brother of the last Duke of Modena, grandson of Victor-Emmanuel IV. The house of Savoy-Carignan, from which the king of Italy springs, does not participate in the Stewart descent.

The branch of the family which the parliamentary settlement called to the throne on the death of Anne were the descendants of the Electress Sophia of Hanover, grand-daughter of James VI. by her mother the Princess Elizabeth Stewart, Electress Palatine and queen of Bohemia. By this destination, not only were the already-mentioned descendants of Charles I.'s daughter, the Duchess of Orleans, excluded, but also the sons of the king of Bohemia and their descendants. The eldest son, Charles Lewis, Duke of Bavaria, is represented through his daughter, the Duchess of Orleans, by the Comte de Paris, grandson of Louis Philippe, late king of the French. Her Majesty Queen Victoria is sixth in descent from and representative of the Electress Sophia, the line of descent being through George I.; George II.; Frederick, Prince of Wales; George III.; and Edward, Duke of Kent.

We have now briefly to notice the most important cadets of the House of Stewart.

DUKES OF ALBANY, EARLS OF MARCH, LORDS OF ANNANDALE AND MAN.—The dukedom of Albany, forfeited on the attainder of Duke Murdoch, nephew of Robert III. (see *infra*), was conferred on Alexander, second son of King James II. of Scotland, who also obtained the earldom of March, and lordship of Anandale and Man. Albany, falling under suspicion of James III., was arrested, and escaping from custody in Edinburgh Castle to France, was attainted. He afterwards took part in a plot with the discontented barons and Edward IV. of England to place himself on the throne, and joining the English army, captured Berwick.

After making his peace with James, and being restored to his dukedom, he again rebelled, and invading Scotland with the Earl of Douglas, was routed at Lochmaben, and once more attainted. He was first married to Lady Catherine Sinclair, daughter of the Earl of Orkney and Caithness, from whom he obtained a divorce on the ground of propinquity of blood, by which his son Alexander was bastardized. By his second wife, the daughter of Bertrand, Count de la Tour d'Auvergne, he had a son John, who was restored to the dukedom, assumed the regency of Scotland in James V.'s minority, and was declared heir to the throne. By the settlement of the crown under Robert II., John, Duke of Albany, would, had he survived James V., have had a preferable claim to Mary. After a regency of eight years, during which he gave offence by his hauteur and French predilections, he returned to France, became governor of Bourbonnais, attended Francis I. in his unfortunate expedition into Italy in 1525, and died in 1536. By his wife, Anne de la Tour d'Auvergne, he left no issue.

DUKES OF ALBANY, EARLS OF FIFE AND MENTEITH.—Robert, second surviving son of Robert II. and Elizabeth Mure, obtained the earldom of Menteith by marriage with its heiress, and the earldom of Fife by indenture with his sister-in-law, the countess, and was appointed Great Chamberlain of Scotland in 1383. He practically exercised the regency during his father's declining years, and continued to wield the supreme authority after the succession of his timid and irresolute brother, Robert III., who bestowed on him the title of Duke of Albany—i. e., of all Scotland north of Forth and Clyde. His unscrupulous ambition led him to get rid of his nephew, the Duke of Rothesay, by starving him, in order to pave his way to the throne; and Prince James was sent abroad by his father, lest he should meet a similar fate. On Robert III.'s death, Albany at once became regent of Scotland, and wielded the chief power of the state during the minority and captivity of James I. By his first marriage to Margaret, Countess of Menteith, he had a son, Murdoch, who, on his father's decease in 1419, succeeded, unchallenged, to the regency. By his second wife, Muriella, daughter of Sir William Keith, the Marischal, he had, besides two younger sons of whom there was no succession, a son, John, created Earl of Buchan, on whom Charles VII. bestowed the office of Constable of France after the battle of Baugé, and who fell at Verneuil, leaving only a daughter, who married the second Lord Seton, and is represented by the Earl of Eglinton. Duke Murdoch married the eldest co-heiress of the Earl of Lennox, and had four sons.

On James I.'s restoration, his vengeance fell on Duke Murdoch, his sons Walter and Alexander, and his father-in-law, Lennox, who were all put to death, and the dukedom of Albany forfeited to the crown. Murdoch's youngest son, James, generally known as 'James the Gross,' escaped to Ireland, where he had a numerous issue by a lady of the family of the Lords of the Isles, some of whom were brought to Scotland, and raised to high honors by James II., and received letters of legitimation, which in the 15th c., conferred far more nearly than at a later date the full rights of legitimacy. The eldest, who was created Lord Avandale, enjoyed for life the estates of the earldom of Lennox, which had belonged to his grandmother, to the exclusion of the descendants of that lady's sisters; and we afterwards find the Earl of Arran, a descendant of the sixth son of James the Gross, entering a protest in the parliament of 1585 regarding the perfect legitimacy of the house of Ochiltree. From the youngest son James (not legitimated), sprung the Stuarts of Ardvorlich, Glenbuckie, and others in Balquidder.

LORDS AVANDALE, OCHILTREE, and CASTLESTUART; EARLS OF CASTLESTUART.—Andrew Stewart, eldest legitimated son of James the Gross, and grandson of Murdoch, Duke of Albany, was created Lord Avandale in 1455, and held the office of Chancellor to James III. On his death without issue in 1488, he was succeeded by his nephew, Andrew, eldest son of his also legitimated brother, Walter, who had three sons.

The eldest of these, Andrew, third Lord Avandale, exchanged his title for that of Ochiltree, and was father of Andrew second Lord Ochiltree, sometimes called the 'Good Lord Ochiltree,' an active promoter of the reformed faith, one of the Lord's of the Congregation, and an accomplice in the assassination of Riccio. One of his daughters became the second wife of John Knox; and his younger son, James, has an unenviable notoriety in history. He was the unprincipled and arrogant favorite of James VI.'s early years; held along with other offices that of Chancellor of Scotland; was created Earl of Arran on the forfeiture of the Hamilton family; and enriched himself with the spoils of the estates of Angus, Mar, Glammis, and other forfeited lords. But his downfall was as sudden as his elevation. At the Raid of Stirling, in 1585, he was stripped of his honors, offices, and spoils, the earldom of Arran being restored to the Hamiltons; and in 1596, he was assassinated by Sir James Douglas. The second Lord Ochiltree was succeeded by his grandson, Andrew, third Lord Ochiltree, who resigned the lordship of Ochiltree to his cousin, Sir James Stewart of Killeith, son of the Earl of Arran, settled in Ireland, where extensive lands were bestowed on him by James VI., and was in 1619 created Lord Stuart of Castlestuart in the peerage of Ireland.

After the death of the fifth Lord Castlestuart in 1684, the title remained dormant till claimed by Andrew, ninth lord, as heir-

male of the body of the first lord, which claim was proved to the satisfaction of the Irish House of Lords in 1774. The younger branch of the house, to whom the title of Ochiltree was transferred, had come to an end in 1673, and Lord Castlestuart claimed also the Ochiltree title; but the evidence adduced by him was held insufficient by the British House of Lords. He was, in 1793, created Viscount Castlestuart, and in 1800, Earl of Castlestuart; and the present and fifth earl is his great-grandson.

LORDS METHVEN.—Henry Stewart, second son of Andrew, second Lord Avandale, became, in 1526, third husband of the Princess Margaret of England, widow of James IV., and divorced wife of Archibald, Earl of Angus. In 1528, he was created Lord Methven He left no children by the queen-dowager, but by a second marriage had a son, who became second Lord Methven, and in the person of whose son, the third lord, the succession terminated.

LORDS DOUNE, EARLS OF MORAY, LORDS ST. COLME.—Sir James Stewart of Beath, third son of Andrew, second Lord Avandale, obtained from James V. the hereditary command of the castle of Doune, with the stewartry of Menteith. He had two sons, from the younger of whom sprang the Stewarts of Burray, in Orkney. The elder son, James, on the dissolution of the monasteries, obtained the lands of St. Colme, and was created Lord Doune in 1581. His son, the second Lord Doune, married Elizabeth, the only child of James Stuart, Earl of Moray, Regent of Scotland, natural son of James V. by Margaret, daughter of John, Lord Erskine (see MURRAY, JAMES, EARL OF), and thereupon became Earl of Moray. This nobleman is known in history as the 'Bonny Earl of Moray,' and fell a victim to his hereditary enemy, the Earl of Huntly, in 1592. His son, the third earl, is believed to have got a new investiture to heirs-male, and from him descends the present and fourteenth Earl of Moray. The ninth Earl became, in 1796, a peer of Great Britain, as Baron Stuart of Castlestuart. Henry Stuart, younger brother of the 'Bonny Earl of Moray,' was made a lord of parliament as Lord St. Colme in 1611, a title which, however, became extinct on his son's death without issue, and the estates reverted to the Earl of Moray. The family of Stuart of Duncarn sprang from a younger brother of the fifth earl.

EARLS AND MARQUISES OF BUTE, LORDS WHARNCLIFFE, LORDS STUART DE ROTHESAY.—Sir John Stuart, a natural son of Robert II., was made hereditary sheriff of Bute and Arran; and his descendant and representative, Sir James Stuart, had a baronetcy conferred on him in 1627. Sir James Stuart, grandson of the above Sir James, a privy councillor to Queen Anne, and a strenuous opponent of the Union, was raised to the peerage as Earl of Bute. The fourth earl was advanced to the Marquisate of Bute. The present peer is the third Marquis. Two grandsons of the third earl were raised to the peerage as Lord Wharncliffe, and a grandson of the same earl, Lord Stuart de Rothesay (the latter title is now extinct); and a grandson of the first marquis as Lord Stuart de Decies.

EARLS OF ANGUS.—Sir John Stewart (commonly called of Bonkyl), brother of James, fifth Steward of Scotland, was progenitor of some of the most considerable branches of the family, and direct ancestor in the male line of James VI. and the Stuart kings who followed him. He married Margaret, daughter and heiress of Sir John Bonkyl of Bonkyl, in virtue of which alliance most of his descendants added the bend or buckle of the Bonkyl coat to the fess of the Stuart escutcheon. The issue of this marriage was five sons—1. Sir Alexander Stewart of Bonkyl; 2. Sir Alan Stewart of Dreghorn; 3. Sir Walter Stewart of Dalswinton; 4. Sir John Stewart of Jedworth; 5. Sir James Stewart of Pierston; and a daughter, Isabel, who married the celebrated Thomas Randolph, Earl of Moray, nephew of Robert Bruce.

The eldest son, Sir Alexander, succeeded to Bonkyl on his maternal grandfather's death, and was father of Sir John Stewart, created Earl of Angus in 1329. The third earl, grandson of this Sir John, was the last male descendant of Sir Alexander of Bonkyl; and on his death, the earldom devolved on his sister, Margaret Stewart, Countess of Angus in her own right. This lady was married to Thomas, Earl of Mar, by whom she had no issue; but she had a natural son, George, by William, first Earl of Douglas (a connection then deemed incestuous, the earl being brother-in-law to her husband), upon whom, on her resignation, the earldom of Angus was conferred by Robert II. in 1389, and who was ancestor of the Douglases, Earls of Angus.

EARLS OF DARNLEY, EARLS AND DUKES OF LENNOX, LORDS OF AUBIGNÉ.—Sir Alan Stewart of Dreghorn, second son of Sir John of Bonkyl, who with his brothers, John and James, fell at Halidon Hill in 1333, was ancestor of this distinguished line. His domains included the extensive lands of Cruickston and Darnley, in Renfrewshire, to which his grandson, Sir Alexander Stewart, added Galston by his marriage with Janeta, daughter and heiress of Sir William Keith of Galston, and widow of Sir David Hamilton of Cadyow.

Sir John Stewart of Darnley, eldest son of this marriage, distinguished himself much in the French wars, when succors were sent from Scotland to the aid of the Dauphin, afterwards Charles VII. He was Constable of the Scots army in France, and contributed greatly to the victory of the Baugé, in recompense for which the lands and lordship of Aubigné and Concressault, in France, were conferred on him, as well as the county of Evreux, with permission for himself and his descendants to quarter the royal arms of France. In 1428, he was one of the ambassadors sent by Charles to negotiate a marriage between the Dauphin and the Princess Margaret of Scotland; and in the following year, along with a younger brother, William, fell at the siege of Orleans. His marriage with Elizabeth, one of the daughters and co-heirs of Duncan, Earl of Lennox, afterwards added the Lennox estates to the family possessions. According to arrangements made by permission of the king of France, the lordship of Aubigné was generally enjoyed by a younger member of the family; it went in succession to the third son of Sir John Stuart, and to his son, Bernard Stuart. The latter, alike distinguished for military and statesmanlike qualities, had a share in the victory of Bosworth, and supported by arms Charles VIII.'s claim to the throne of Naples. He held, among other dignities, those of Viceroy of Naples, Constable of Sicily and Jerusalem, and Duke of Terra Nova.

His grandson, Sir John Stuart, was advanced to the dignity of a lord of parliament under the title of Lord Darnley; he was also served heir to half the Lennox domains, and claimed the earldom of Lennox. His elder son, Matthew, second earl of Lennox, fell at Flodden; his younger son, Robert, got the lordship of Aubigné in 1508, on the death, without issue, of Bernard Stuart, whose daughter was his first wife. John, the third Earl of Lennox, was son of the second earl by Elizabeth, daughter of James, Lord Hamilton, and niece of James III.; he was one of the lords of the regency in James's V.'s minority, and in endeavoring to rescue the youthful king from the thraldom of the Douglases, he was taken prisoner at Linlithgow, and murdered by Sir James Hamilton of Finnart, Arran's natural son. This earl was married to Lady Anne Stewart, daughter of John, Earl of Athole, and had three sons, Matthew—who succeeded him as fourth earl—Robert, and John. The termination of the male line of Robert III. by the death of James V., along with the imperfect legitimacy of the descendants of the house of Albany, placed Matthew Earl of Lennox, in the position of heir-male of the Stewards of Scotland. He married Lady Margaret Douglas, only child of Archibald, Earl of Angus, by the queen-dowager Margaret, sister of Henry VIII., an alliance which brought his children into the position of being nearest heirs after Mary, Queen of Scots, to the crown of England. The issue were two sons, the elder of them the unhappy husband of the unhappy Queen Mary, and father of James VI.

Lennox, after spending his youth in France and in the wars in Italy, returned home in 1543, and took an active part in the negotiations for the proposed marriage of Queen Mary with Edward VI. His subsequent intrigues with England led to his banishment and attainder, but he was recalled and restored to his honors by Mary. After that queen's forced resignation, he was appointed to the regency, and when on his way to hold a parliament at Stirling in 1571, he was attacked by a party of the queen's friends and mortally wounded.

The earldom and estates of Lennox, which, on the death of the fourth earl, had devolved on James VI. by right of blood, were conveyed by him to his uncle, Charles, fifth Earl of Lennox, brother of Lord Darnley. The marriage of this earl in 1574, with a sister of the first Earl of Devonshire, gave great displeasure to Elizabeth, whose own doubtful legitimacy made her very sensitive to possible pretensions to the throne. The sole issue of that union was a daughter, Arabella, and the earldom went in succession to the fifth earl's uncle, Robert, Bishop of Caithness, and his cousin, Esme, son of John Stewart, Lord of Aubigné, youngest son of the third Earl of Lennox, who was created Duke of Lennox. The near relationship to the crown, both of England and Scotland, in which the fifth earl's daughter, the unfortunate Lady Arabella Stewart, stood, made her an object of jealousy equally to James and Elizabeth.

Elizabeth first interfered to prevent her contemplated marriage with her cousin, Esme, Duke of Lennox, and afterwards imprisoned her for listening to overtures from a son of the Earl of Northumberland. The result was, that this lady formed an illicit connection with William Seymour, afterwards Marquis of Hertford; on the discovery of which, both were summoned by James before the Privy Council, and severely reprimanded. The consequence was the reverse of what was intended. Lady Arabella privately married Seymour; which becoming known, she and her husband were committed into custody. Both effected their escape: Lady Arabella was overtaken in Calais Roads, and imprisoned in the Tower, where these undeserved oppressions drove her to a condition of lunacy, in which she died, 27th September 1615. Esme, first Duke of Lennox, had two sons, Ludovic and

Esme, successively second and third Dukes of Lennox. The former held the offices of Great Chamberlain and High Admiral of Scotland, and was created Earl of Richmond, Earl of Newcastle, and Duke of Richmond in the peerage of England. The latter, who was also Lord of Aubigné, was created Earl of March in England, and was father of James, fourth Duke of Lennox, who fell under the guardianship of James VI. as his nearest heir-male, and had the title of Duke of Richmond, which had expired at his uncle's death, revived in his favor in 1641. On the death of the sixth and last duke without issue in 1672, King Charles II., as nearest heir-male, was served heir to him in special.

LORD PITTENWEEM.—Alexander Stewart of Galston, younger brother of the first Lord Darnley, got from his brother the lands of Dreghorn and Galston. His great-grandson, Thomas Stewart of Galston, had two sons, Thomas and William. The younger son, William, became commentator of the Priory of Pittenweem, and his son was made a Lord of Parliament as Lord Pittenweem. The line of the elder son, Thomas, failed in 1650 in the person of Ludovic Stuart of Galston.

STUARTS OF CASTLEMILK.—The earliest proved ancestor of this important and well-allied branch of the Stewarts, was Sir William Stewart of Castlemilk, who in 1398 was appointed umpire for the preservation of the Western Marches, probably descended from the Stewarts of Darnley. Archibald Stewart of Castlemilk was created a baronet of Nova Scotia by Charles II. His line failed on the death of Sir John Stuart, fifth baronet, in 1797, when the succession devolved on Andrew Stuart of Torrance and Castlemilk, M.P., the author of *The Genealogical History of the Stewarts*, descended from an uncle of the first baronet, who died without issue.

STEUARTS OF ALLANTON, COLTNESS, &c.—This family, which first came into notice in the 16th c., and includes various men of eminence who would do honor to any line of ancestry, is of unascertained descent, but some traditional accounts make it a branch of Castlemilk. Sir James Steuart of Coltness and Kirkfield, younger brother of Sir Walter of Allanton, and his son, Sir Thomas, were active Covenanters; and the latter, an energetic member of King William's first parliament, and the framer of the Act of 1690 for the regulation of the Church of Scotland, was in 1698 made a baronet. His son, Sir David Steuart of Coltness, accompanied Archibald, Earl of Argyll, in his descent on Scotland, for which he was sentenced to death, but escaped, and was afterwards pardoned. His brother, Sir Robert Steuart, fourth baronet, was among the more distinguished scientific men of the beginning of the 18th c., and filled the Natural Philosophy chair in the university of Edinburgh, in which he was succeeded by his son. Sir James Steuart of Goodtrees, Lord Advocate under King William and Queen Anne, author of the Answers to *Dirleton's Doubts*, and one of the most eminent jurists of his time, was younger brother to the first baronet of Coltness. His son, Sir James Steuart of Goodtrees and Coltness, also a distinguished lawyer, and created a baronet in 1705, was father of another Sir James, who was Prince Charles's confidential agent at the Court of France, and at the same time the author of various works of merit on political economy and kindred subjects.

EARLS OF GALLOWAY.—Sir Walter Stewart of Dalswinton, third son of Sir John of Bonkyl, obtained the lands of Dalswinton from King Robert Bruce, and Garlies from his nephew, John Randolph, Earl of Moray. His grandson, Sir Walter of Dalswinton, left an only daughter, Marion, who married Sir John Stewart, son of Sir William Stewart of Jedworth, and probably a descendant of John, fourth son of Sir John of Bonkyl. Sir Alexander Stewart of Garlies, eighth in descent from Sir John and Marion Stewart, was created Lord Garlies in 1607, and Earl of Galloway in 1623. In 1796, John, seventh Earl of Galloway, was created a British peer as Baron Stewart of Garlies. Alan Plantagenet Stewart, tenth Earl of Galloway, is present representative.

LORD BLANTYRE.—This branch of the House of S. is descended from Sir Thomas Stewart of Minto, third son of Sir William of Dalswinton and Garlies, the eldest son of the heiress, Marion Stewart. Sir John Stewart of Minto, great-grandson of that Sir Thomas, had two sons. The line of the elder, Sir Matthew, became extinct in the person of Sir John Stuart, who died in the Darien expedition of 1697. The second son, Walter, was educated along with James VI. under George Buchanan, and had the priory of Blantyre bestowed on him by that monarch: he was Privy Councillor, Keeper of the Privy Seal, one of the four Commissioners of the Treasury and Exchequer, called Octavians, and afterwards High Treasurer. In 1606 he was raised to the peerage as Lord Blantyre. The present representative of this branch is Charles Stuart, twelfth Lord Blantyre.

VISCOUNTS MOUNTJOY. EARL OF BLESSINGTON.—Sir William Stewart, descended from Walter Stewart of Tonderghie, fourth son of Sir William of Dalswinton and Garlies, who was in great favor with James VI., and undertaker for the plantation of escheated lands in Ulster, was made a baronet of Ireland in 1623. His grandson, Sir William Stewart, second baronet, was in 1682 created Baron Stewart of Ramalton, and Viscount Mountjoy in the peerage of Ireland. He served in Hungary at the siege of Buda, and in 1688 undertook a mission from Lord-deputy Tyrconnel to James II., then at Paris, when he was thrown into the Bastille, and was a prisoner there for four years. He afterwards joined King William at Flanders, and was killed at the battle of Steinkirk. The second viscount, his son, married the daughter and eventually heiress of Viscount Blessington. Their son, the third Viscount Mountjoy, was advanced to the Earldom of Blessington, which title, as well as that of Mountjoy, became extinct on his decease in 1769, though the baronetcy exists.

EARLS OF ATHOLE, LORDS OF LORN AND INNERMEATH.—Sir James Stewart, fifth son of Sir John of Bonkyl, killed with his brothers Alexander and John at Halidon Hill, had a grant from Robert Bruce of the lands of Pierston and others in Ayrshire, and was father of Sir Robert Stewart of Shanbothy and Innermeath. This Sir Robert had two sons, John and Robert, who married the two co-heiresses of the princely house of De Ergadia, Lord of Lorn, who were also co-heirs of the line of Robert Bruce. The younger son, Robert of Durrisdeer, was ancestor of a line of Stewarts of Rossyth and Craigiehall, to whom Oliver Cromwell's mother is said, on no very certain grounds, to have belonged, and which probably came to an end about 1830. The elder son, Sir John, whose wife was the elder and principal co-heiress, had five sons. The eldest, Robert, became Lord of Lorn; the third, Sir James, known as the Black Knight of Lorn, was husband of James I.'s widow; and his eldest son, brother uterine of James II., was created Earl of Athole, with remainder to the heirs-male of his body. His great-grandson, John Stewart, fourth Earl of Athole, was much involved in the political events of Mary's and James VI.'s time. An adherent of the old faith, and at first a staunch supporter of the queen, he nevertheless assisted in her seizure, and took a lead in the association formed in 1567 for the defence of James VI. He headed the confederacy which took up arms against the Regent Morton, and induced James to call a parliament. In 1577, he became Chancellor of Scotland, and died suddenly under suspicion of poison from Morton. His son, the fifth Earl of Athole, had no male issue, but daughters, of whom the eldest was married to the Earl of Tullibardine; and at his death, the earldom fell to the crown, and was conferred on the elder branch of the House of Innermeath, to which we now revert.

Robert, Lord of Lorn, eldest brother of the Black Knight, had two sons. The elder of these, John, second Lord of Lorn, had three daughters, co-heiresses, who respectively married the Earl of Argyll, Campbell of Glenorchy, and Campbell of Ottar, the lordship of Lorn passing to the Argyll family; he had also a natural son, ancestor of the Stewarts of Appin. The second son of Robert, Lord of Lorn, was Walter, Lord Innermeath, whose descendant and representative, John, sixth Lord Innermeath, obtained the earldom of Athole on the death of the above-mentioned fifth earl; with a remainder to the heirs-male of his body, which came to an end on the death, in 1625, of his only son, who had succeeded him in the earldom. The earldom of Athole was then conferred by Charles I. on the Earl of Tullibardine, grandson through his mother of the fifth Earl of Athole, from whom the existing ducal House of Athole is descended. From Alexander, fourth son of Sir John Stuart of Innermeath, descend the family of Stewart of Grandtully, on whom a baronetcy was conferred in 1683.

EARLS OF BUCHAN.—The earldom of Buchan was, in 1469, bestowed on James Stewart, second son of the Black Knight of Lorn, and brother uterine of James II. By his marriage with the heiress of Auchterhouse, his family became heritable sheriffs of the county of Forfar. His legitimate line ended in the fourth generation in an heiress, Christian, Countess of Buchan, who, marrying a son of Sir Robert Douglas of Lochleven, carried the earldom of Buchan into his family.

EARLS OF TRAQUAIR.—This James Stewart, first Earl of Buchan, had, besides his lawful issue, a natural son, James, legitimated in 1489, on whom his father conferred the lands of Traquair. His descendant, Sir John Stuart, was created by Charles I. Lord Stuart of Traquair in 1628, and in 1633, Earl of Traquair. The title became extinct or dormant on the death of the eighth earl in 1861.

Various works have been written to elucidate the history of the S. family, or particular branches of it, including Symson's *General and Historical Account of the Stewarts* (Edin. 1712); Hay of Drumboote's *Essay on the Origin of the Royal Family of the Stewarts* (1722); Duncan Stewart's *Historical and Genealogical Account of the Royal Family of Scotland, and of the Surname of Stewart* (Edin. 1739); Noble's *Historical Genealogy of the Royal House of Stewart* (Lond. 1795); and Andrew Stuart of Castlemilk's *Genealogical History of the Stewarts* (Lond. 1798), a work full of laborious research, but nearly confined to the Houses of Darnley, Lennox, and Castlemilk. See also *The Genealogy of the Stewarts refuted* (Edin. 1799), and the rejoinder to it in Andrew Stuart's *Supple-*

ment to the Genealogical History of the Stewarts (1799); Chalmer's *Caledonia* (1807—1824); Crawford's *Description of the Shire of Renfrew, with Supplement* by George Robertson (Paisley, 1818); Fraser's *Red Book of Grandtully* (Edinburgh, 1868).

STEWART, DUGALD. This philosopher was born in Edinburgh, on the 22d November 1753. His father was Matthew Stewart, Professor of Mathematics in the university of Edinburgh. He entered the High School in his eighth year, and remained till his thirteenth. During the last two years of his attendance, when in the rector's classes, he was principally under Alexander Adam, afterwards well known for his classical scholarship, who then began to teach as the rector's substitute. His subsequent course at the university extended from 1765 to 1769. In the departments of study where his own career afterwards lay, he was fortunate to find professors of ability and distinction; the logic chair was filled by John Stevenson, who lectured on logic, metaphysics, rhetoric, and the history of philosophy; the Moral Philosophy chair was occupied by Adam Ferguson. While S. gave his highest promise in these subjects, he also made great attendance in mathematics and natural philosophy, and likewise in classics. In 1771, he went to study at Glasgow, partly with a view to one of the Snell scholarships at Baliol College, Oxford, and partly to attend the lectures of Dr. Reid. It was while there that he wrote an essay on Dreaming, which was his first effort in mental philosophy, and contained the germs of many of his subsequent speculations. He lived in the same house with Archibald Alison, the author of the *Essay on Taste*, and the two became intimate friends through life. He was at Glasgow only one session.

In 1772, in his 19th year, he was called upon by his father, whose health was failing, to teach the mathematical classes in the university of Edinburgh; in 1775, he was elected joint professor, and acted in that capacity till 1785. In 1778, Adam Ferguson was absent from his post on a political mission to America, and S. taught the moral philosophy class in addition to his mathematical classes. The lectures that he gave on this occasion were wholly his own, and were delivered from notes, as was his practice in after years. On the resignation of Ferguson in 1785, he was appointed Professor of Moral Philosophy, and continued in the active duties of the class for 25 years. His lectures were greatly admired and numerously attended. He went over a wide compass of subjects: Psychology, or the Science of Mind proper, Metaphysics, Logic, Ethics, Natural Theology, the Principles of Taste, Politics, and last of all, Political Economy, which, from the year 1800, he treated in a separate course. In 1792, appeared his first volume of the *Elements of the Philosophy of the Human Mind*. In 1793, he published his *Outlines*. He read before the Royal Society of Edinburgh, in 1793, his *Account of the Life and Writings of Adam Smith;* in 1796, the *Account of the Life and Writings of Principal Robertson;* and in 1802, the *Account of the Life and Writings of Dr. Reid*. In 1805, he took a prominent part in the Leslie controversy; being the author of a pamphlet setting forth the facts of the case, and also, in the General Assembly, giving vent to his indignation at the proceedings against Leslie.

In 1806, on the accession of the Whig party to power, he received a sinecure office worth £300 a year. The death of his second son, in 1809, gave a blow to his health, otherwise indifferent, and he was unable to lecture during part of the following session; Dr. Thomas Brown, at his request, acting as his substitute. The following year, Brown was appointed conjoint professor, and taught the class till his death in 1820. From 1809, S. lived in comparative retirement at Kinneil House, Linlithgowshire, which the Duke of Hamilton placed at his service. In 1810, he published his *Philosophical Essays;* in 1814, the second volume of the *Elements;* in 1815, the first part, and in 1821, the second part, of the *Dissertation on the History of Ethical Philosophy;* in 1827, the third volume of the *Elements;* and in 1828, a few weeks before his death, the *Philosophy of the Active and Moral Powers*.

On the death of Brown, S. exerted himself to secure the appointment of Sir W. Hamilton to the chair, but the influence used with the Town Council in behalf of John Wilson was overpowering; the votes stood 21 for Wilson, 9 for Hamilton. S. resigned his conjunct professorship on the 20th June 1820.

The philosophy of S. was the following up of the reaction commenced by Reid against the sceptical results that Berkeley and Hume drew from the principles of Locke. Both Reid and S. professed the Baconian method of observation and induction, as against mere ontology, but considered that these processes of investigation could establish certain ultimate truths of a higher certainty than themselves. Hence arose the principles of common sense of Reid, in which S. for the most part acquiesced. S. also followed and improved upon Reid in that systematic exposition of all the powers of the mind which rendered mental philosophy for the first time a subject of study, independent of metaphysical, logical, and ethical applications; although he also followed it out in all these directions with his usual perspicacity and felicity of exposition. His contributions to the philosophy of Taste, in the *Philosophical Essays*, are among the best parts of his writings.

On the whole, although S. was not one of the most original thinkers in his department, yet, by the force of his teaching and the compass of his writings, he did more than almost any man to diffuse an interest in the speculations connected with the human mind. His collected works have been edited by Sir W. Hamilton, in 11 vols., to which Professor Veitch has contributed his biography.

STEW'ARTON, a town of Scotland, county of Ayr, on the right bank of the Annock, five miles north-west of Kilmarnock, and a station on the Glasgow and South-Western Railway. It is a trim, well-built, and prosperous place. S. owes its prosperity to its woollen and Scotch bonnet manufactures; but it also carries on a variety of minor industries, such as carpet-weaving, Ayrshire needle-work, and the making of spindles for mills. Pop. (1881) 3130.

STEW'ARTRY, the name which was given in Scotland to a district governed by a steward, an officer appointed by the king with jurisdiction over crown-lands, and powers similar to those of a lord of regality. While the civil jurisdiction of a steward was equivalent to that of a sheriff, his criminal jurisdiction was much more extensive. The only remaining trace of this jurisdiction exists in the term stewartry, which in place of county is applied to the district of Kirkcudbright.

Galloway was in early times rather a tributary dependency of Scotland than an integral portion of the kingdom, and retained its old Celtic proprietary, and peculiar laws and usages, which were adverse to the introduction of a sheriffdom. It was for a long time ruled by a line of lords, who were among the most powerful feudatories of the Scottish crown. The Comyns, who in the course of time succeeded to the lordship, were overthrown and expatriated by Bruce; and it seems to have been on their forfeiture that Eastern and Central Galloway were erected into the present stewartry. Western Galloway being already under the jurisdiction of the sheriff of Wigton. On the abolition of heritable jurisdictions in 1747, various regalities and baronies which had existed within the district were done away with, and the emancipated stewartry was placed under a steward-depute, whose functions were in every practical point of view the same as those of a sheriff-depute. Act 1 Vict. c. 39, declares that in any existing or future statute the words sheriff, sheriff-clerk, &c. shall be held to apply to steward, steward-clerk, &c.

STEWING, in Cookery, a very economical way of preparing meat and fruits for food. It differs from boiling in this respect, that only a small quantity of water is used, and the heat applied is so gentle as only to *simmer* it. A stew-pan should be well fitted with a lid, and the more slowly the ebullition is carried on the better. As the small quantity of water is retained as gravy, nothing is lost. Meat prepared in this way is tender, and savory, but owing partly to the richness of the gravy is not very digestible.

STEY'ER, a town of Upper Austria, at the confluence of the Steyer and the Enns, 23 miles south-east of Linz. It is a great seat of the iron and steel manufactures of Austria, and also carries on important manufactures of paper, woollens, and hosiery. Pop. (1880) 17,199.

STHAVIRA (a Sanscrit word, meaning *old*) is, in Buddhist hierarchy, the name of the 'elders' or 'venerables,' who, after the death of *the* Buddha S'âkyamuni, taught the doctrine, presided at the Buddhist assemblies, &c., and, since the time of As'oka, were invested with a kind of episcopal power. In the sectarian history of Buddhism, Sthavira is the name of those Arhats who did not follow the schism of the Mahâsânghikas (q. v.), but adhered to the old doctrine. According to another account, the Sthaviras are one of the four divisions of the Vaibhâshika system of Buddhism, and claim for their founder Kâtyâyana, the disciple of S'âkyamuni.—See C. F. Koeppen, *Die Religion des Buddha* (Berlin, 1857); and W. Wassiljew, *Der Buddhismus, seine Dogmen, Geschichte und Literatur* (St. Petersburg, 1860).

STICKING-PLASTER, or COURT-PLASTER, is best prepared in the following manner: Two solutions are first made, one of an ounce of isinglass in eight ounces of hot water, and the other of two drachms of gum-benzoin in two ounces of rectified spirit. These solutions are to be strained and mixed. Several coats of this mixture, kept fluid by a gentle heat, are then to be applied with a camel's-hair brush to a piece of black silk stretched on a frame, each coat being allowed to dry before the next is applied. A layer of a solution composed of one ounce of Chian turpentine in two ounces of tincture of benzoin, is then to be applied to the other side of the silk, and allowed to dry. In place of the ordinary black sticking-plaster, some persons prefer colorless plaster, or *Gold-beater's Skin* (q. v.).

STI'CKLEBACK (*Gasterosteus*), a genus of acanthopterous fishes, referred by many naturalists to the family of Mailed Cheeks

(q. v.) (*Sclerogenidæ* or *Triglidæ*); by others, to a distinct family (*Gasterosteidæ*), in which the first dorsal fin is represented by a number of detached spines, a single strong spine occupies the place of the ventral fins, there are only three branchiostegal rays, the gill-covers are not armed, and the body is mailed by plates on the lateral line, and destitute of scales. The species are found in fresh and brackish waters, and in the sea, in cold and temperate regions; and are small fishes, very interesting from their habits and the beauty of their colors, which they change in a remarkable manner, partly according to the colors of surrounding objects, and partly through the influence of their own passions.

The THREE-SPINED S. (*G. aculeatus* or *trachurus*), having three spines instead of the first dorsal, is extremely abundant in rivers, ponds, and brackish waters in most parts of Britain and of Europe, and is sometimes also found in the sea. Sticklebacks caught in a river readily accommodate themselves to living in a salt-water aquarium. It seldom exceeds two inches and a half, or three inches in length. Cuvier and Valenciennes, Yarrell, and others

Sticklebacks and Nests.

distinguish from this several other species, some of which are also British, differing in size, the armature of the sides, and other particulars (4 to 15 spines); but some naturalists are still inclined to regard them as mere varieties. The common fresh-water species are sometimes so abundant in ponds, ditches, and the still parts of rivers, as in Lincolnshire and other flat parts of the east of England, that they are used for manure. They are seldom used as food, yet they are said to be excellent for this purpose. Oil has sometimes been expressed from them.

In the aquarium, or in their native waters, their combats are very amusing. They are excessively pugnacious, particularly at the breeding season. The larger often devour the smaller, and they destroy the fry of fishes to a prodigious extent; they feed also on aquatic larvæ, and are probably of great use in preventing the excessive multiplication of many kinds of insects. Their nest-building is particularly interesting, and in them nest-building was first observed among fishes. They collect small pieces of straw or stick, with which the bottom of the nest is laid among water-plants, and these they cement together by an exudation from their own bodies, which forms a thread through and round them in every conceivable direction. The thread is whitish, fine, and silken. The sides of the nest are made after the bottom. The nest of the Fresh-water S. is about the size of a small hazel nut. The eggs, about the size of poppy-seeds, are deposited within. The male makes the nest, into which he introduces the female for the laying of the eggs, and he afterwards watches it with great care—a care not unnecessary, as the eggs are most acceptable food to any other S. which can get at them.

STIFF-NECK (known also as WRY-NECK or TORTICOLLIS) is the term commonly applied to a condition of the neck in which lateral movement of the head causes great pain, and which is due to rheumatism of the muscles lying on the side of the neck, especially the sterno-mastoid. In the great majority of cases, only one side of the neck is affected, the head being drawn more or less obliquely towards that side; but occasionally both sides are equally attacked, in which case the head is kept stiffly erect and looking straight forwards. As long as the head is allowed to remain at rest, there is merely a feeling of discomfort; but every movement is extremely painful. This affection is usually caused either by exposure of the part affected to a current of cold air, or by wearing wet or damp clothes around the neck. In addition to the ordinary treatment of sub-acute Rheumatism (q. v.), heat may be advantageously employed, either, as suggested by Dr. Wood of Philadelphia, by placing a batch of carded tow or cotton over the part, and then applying a hot flat-iron, or by the direct application of a small heated iron hammer, as recommended by Drs. Corrigan and Day. For the method of applying this hammer, and for cases illustrative of its use, the reader is referred to the last-named physician's memoir *On the Thermic Treatment of Lumbago and other Forms of Muscular Rheumatism*.

STIGMA. See PISTIL.

STIGMARIA, the root of Sigillaria (q. v.).

STIGMATIZA'TION (Lat *stigmatizatio*, a puncturing, from Gr *stigma*, a puncture), the name applied, by the mystic writers of the Roman Catholic Church, to the supposed miraculous impression on certain individuals of the 'stigmata,' or marks of the wounds which our Lord suffered during the course of his Passion. These stigmata comprise not only the wounds of the hands and feet, and that of the side, received in the crucifixion, but also those impressed by the crown of thorns and by the scourging. The impression of the stigmata, being held to be miraculous was regarded as a mark of the signal favor of our Lord, manifested to those who were specially devoted to the contemplation of his Passion. The most remarkable example of stigmatization is that already referred to in the memoir of FRANCIS OF ASSISI (q. v.), which is said to have occurred on the mountain of Alverno, upon the 15th September 1224, two years before the death of Francis. Being absorbed, according to the account of his biographers, in profound and rapturous contemplation of the Passion of Christ, he saw, as it were, a seraph with six shining wings, blazing with fire, and having between his wings the figure of a man crucified, descend from heaven, and approach him, so as to be almost in contact. After a time, the vision disappeared, but left the soul of Francis filled with reverence and awe; and on his return to calmer thought, he became aware that his body had received externally the marks of the crucifixion.

His hands and feet seemed bored through with four wounds, and these wounds appeared to be filled with nails of hard flesh, the heads of which protruded and appeared upon the palms of his hands, and on the instep, while the points protruded upon the opposite side, and seemed as if clenched with a hammer. His side, moreover, presented a red wound, as though from the point of a lance, and this wound occasionally gave forth blood. These mysterious marks continued, and were frequently seen by St. Bonaventure and others during the two years which intervened between this date and the death of Francis; and they were seen by multitudes after his death.

It would be out of place here to enter into any discussion as to the origin, or the nature, of this strange phenomenon. But the case of Francis of Assisi is by no means a solitary one; very many others, women as well as men, are recorded as having received all or some of the stigmata. The cases of women so visited are more numerous than those of men. A very remarkable one is that of Veronica Giuliani, in 1694, who is related to have received first the marks of the crown of thorns, and afterwards those of the crucifixion; Gabriella da Piezolo of Aquila is recorded to have received the mark of the lance in 1472; Clara di Pugny, a Tertiary of the Dominican order, was similarly impressed in 1514; and Cecilia di Nobili of Nocera in 1655.

Catherine di Raconisio is alleged to have been marked with the crown of thorns in 1583, and the same is related of several others, as Maria Razzi of the island of Chio, Maria Villani, Vincenza Ferreri of Valencia, and Joanna Maria of the Cross, a nun of St. Clare, at Roveredo. In some cases, the visitation, although said to be accompanied with excruciating pain in the seat of the several wounds, was unattended by any external marks. Such was the case of St. Catherine of Siena, of Ursula Aguirre—otherwise known as Ursula of Valencia—of Mary Magdalen di Pazzi, and of Mechtildis von Stanz; while in other cases the wounds were in part visible, and in part invisible. Thus, Hieronyma Carvaglio suffered the pain of the wounded hands and feet without any external mark, while the lance-wound was not only visible in her side, but was reported to bleed upon every Friday, the day especially devoted to the commemoration of the Passion. Blanca de Gazeran experienced the sensation of pain in the seat of each one of the wounds, but the mark of the nail was visible upon the right foot only. The same variety of sensation is recorded in several other cases.

Most of the cases recorded hitherto are of females; and that examples of these are not wanting even in more recent times, the case of the well-known 'Estatica' of Caldaro, about 40 years ago, and that of Louise Lateau, discussed quite recently, sufficiently attest. But, besides that of Francis of Assisi, instances are also recorded in which men were reputed to have received the stigmata. A Capuchin named Benedict, of Reggio, is said to have received the marks of the crown of thorns in 1602. A lay-brother named Carlo di Saeta, or Sazia, was smitten in a vision with the wound in the side. Angelo del Paz, a Franciscan, is related to have borne for many years all the stigmata, as also a Premonstratensian monk named Dodo, and a Franciscan called Nicholas of Ravenna. Several cases also are mentioned of men, who, without the visible or external stigmata, experienced at regular intervals the painful sensation by which the stigmata are accompanied. Many such cases are detailed by the celebrated German mystic, Görres, in his *Christliche Mystik*, vol. ii. pp. 420—456.

STILAGINA'CEÆ, a natural order of exogenous plants, allied to *Urticeæ*, containing about twenty known species of trees and shrubs, natives of the East Indies, Mauritius, and Madagascar. None of them are of importance.

STI'LBITE. See ZEOLITE.

STILICHO, a celebrated Roman general, the mainstay of the Western Empire after the death of Theodosius (q. v.) the Great, is said to have been a Vandal, and was the son of a captain of barbarian auxiliaries in the imperial army. He rose through his military talent to high rank in the army, and Theodosius was so pleased with his rare ability, zeal, and accomplished manners, that he gave him his niece Serena in marriage. S.'s promotion was, however, viewed with great jealousy by Rufinus, the able but evil-minded and ambitious minister of Theodosius, and an inextinguishable feud arose between the two, which it required all the weight of the emperor's influence to repress. In 394, S. departed for Rome in charge of the youthful Honorius (q. v.), who had been committed to his care, placed him on the throne of the Western Empire, and administered in his name the affairs of state. On the death of Theodosius, towards the close of 394, the quarrel for supremacy between S. and Rufinus, the guardian of Arcadius (q. v.), became fully developed, and Alaric (q. v.) at the instigation of the latter, invaded Greece while S. was engaged in chastising the invaders of the Roman territories on the Rhine and in Gaul.

S., on his return, at once set out for Constantinople, and put an end to the struggle between himself and Rufinus by the destruction of his rival in 395. He then marched against Alaric, blocked him up in the Peloponnesus, but, through over-confidence, permitted him to escape across the isthmus with his captives and booty. In 398, his daughter Maria became the wife of Honorius. His old opponent, Alaric, after several inroads upon the eastern provinces of the Western Empire, now invaded Northern Italy, but was signally defeated at Pollentia (March 403) by S., who had hurriedly called in the Roman legions from Rhætia, Gaul, Germany, and even Britain. He was again defeated at Verona, upon which he retired from the empire, and S. obtained the honor of a triumph and a great increase of influence and power. S.'s ambition now led him to attempt the introduction of his own family to the imperial succession (a statement disbelieved by Gibbon, who considers it merely as an invention of the crafty Olympius; though the great historian of the Roman Empire honestly confesses to various heavy blots on the character of his hero), by the marriage of his son with the heir-presumptive Placidia, the daughter of Theodosius, and to attain this end, he made overtures of alliance to Alaric, which were gladly accepted. But the dreadful inroad of Radagaisus, in 406, at the head of more 200,000 (some say 400,000) barbarians, who ravaged the whole country as far as Florence, compelled the great general of the West to shelve for a time his ambitious schemes. With a small but chosen army of veterans, aided by a body of Huns under Uldin (father of Attila), and of Visigoths under Sarus, he so harassed the invaders, that they were forced to give him battle. They were soon routed. Radagaisus, who surrendered, was put to death, and his followers sold as slaves.

S. again resumed his pet scheme; established enmity between Rome and Byzantium by seizing on Eastern Illyricum and inducing Alaric to transfer his allegiance to Honorius. But Honorius, who had been prejudiced against S. by one of his officers, Olympius, refused to take Eastern Illyricum from the Byzantine Empire; and subsequently, by an artful harangue, he so influenced the soldiers of the army of Gaul, that they rose *en masse* against the partisans of Stilicho. S. himself was at Bologna; and on the news of the *émeute*, his most zealous friends urged immediate action against Olympius and the Pavian rebels; but for the first time in his life, vacillation seized S., and he declined. They then, for self-preservation, turned against him, and one of them, Sarus, the Goth above mentioned, drove him out of his camp, and compelled him to flee to Ravenna, where he was soon afterwards slain, 23d August, 408. Thus perished the last of the series of distinguished aliens, who, as emperors, warriors, or politicians, had propped up the Roman empire for 150 years, with a stern and resolute zeal equal to that of the early Romans themselves. After protecting the weak empire from formidable invasion by his own kinsman, administering its affairs with remarkable ability, moderation, and integrity, and restoring its old heroic glory to the imperial arms, S. received the reward which alone an effete and conceited people can be expected to bestow; and three months after his death, Alaric and his Visigoths were at the gates of Rome.

STILL is the apparatus employed for the distillation of liquids, and consists of the copper boiler or *alembic* (see DISTILLATION), in which is contained the fermented liquor whose vapors are to be distilled; of the *neck* or *head*, a pipe which conveys the vapor generated in the boiler into the worm; and of the *worm*, a coiled metal tube which is packed in a vessel called a *refrigeratory*, fitted up in such a manner that the cold water which is poured in at the top comes in contact as extensively as possible with the outside of the tube, and exercises a condensing action upon the vapor which it contains. The vapor thus condensed in its passage through the worm, makes its exit in drops, or in a small stream, into a vessel called the *recipient*, and may be redistilled or not as is required. The various forms of stills are extremely numerous, almost each species of spirit possessing its own form of still, but they all conform to the general description above given.

STILLINGFLEET, EDWARD, Bishop of Worcester was born April 17, 1635, at Cranbourne, in Dorsetshire. He received his early education at the grammar-school of his native place, and in 1648 became a student at St. John's College, Cambridge. He took his degree as Master of Arts; and in 1653 succeeded in obtaining a Fellowship. For some years after leaving college, he was occupied as a private family tutor; and in 1657 he was presented to the rectory of Sutton. In 1659, he came before the world as an author in the work entitled *Irenicum, or the Divine Right of Particular Forms of Church Government examined*. The views here maintained savored somewhat more of latitudinarianism than could be pleasant to the High Church party, and he afterwards saw reason to modify them. His next performance was the *Origines Sacræ, or Rational Account of the Christian Faith, as to the Truth and Divine Authority of the Scriptures*, a work which made his reputation, and is still had in estimation as one of the most masterly treatises extant on the subject of which it treats. In 1664, appeared his *Rational Account of the Grounds of the Protestant Religion*, a defence of the Church of England from the charge of schism in its separation from that of Rome, which was received with great favor, and led to the preferment of its author.

In 1665, the Earl of Southampton presented him to the rectory of St. Andrews, Holborn; he was also appointed preacher at the Rolls Chapel, and shortly after lecturer at the Temple, and Chaplain in Ordinary to Charles II. In 1670, he became, by favor of the king, Canon Residentiary of St. Paul's Cathedral, and in 1678, was preferred to be Dean of the same. In the Court of Ecclesiastical Commission instituted by James II., S. declined to act; and after the Revolution of 1688, he received, in final acknowledgment of his services to the Protestant cause, his appointment to the bishopric of Worcester. He died at Westminster on 27th March 1699, and was buried in Worcester Cathedral.

S.'s chief works, besides those mentioned, were the *Origines Britannicæ, or Antiquities of the British Churches*, and a bulky volume entitled *The Unreasonableness of Separation*, in reply to an attack made upon him by Howe and others. Throughout, he was besides almost constantly engaged in religious controversy, on the one hand with the adherents of the Church of Rome, and on the other with the Noncomformists. Of his numerous polemical treatises, however important in their day, it is not here necessary to treat in detail. His collected works, in 6 vols. folio, were published in 1710; and in 1735, a supplementary volume of Miscellanies was issued by his son, the Rev. James Stillingfleet, Canon of Worcester. S., though keen and unsparing in conflict, was a good and amiable man, and his unquestioned piety and honesty of intention commanded throughout the respect even of his bitterest opponents.

STILL-LIFE is the name applied to that branch of art which concerns itself with the representation of lifeless objects, such as dead animals, fruits, flowers, vases, and house-furniture.

STILTED ARCH, an arch in which the impost moulding is placed at some distance below the springing of the arch.

STI'MULANTS may be defined to be agents which produce a sudden but not a permanent augmentation in the activity of the vital functions. They give increased energy to the circulatory and cerebro-spinal nervous systems, the primary effect being probably on the nervous system, while the circulation is only secondarily affected. In their mode of action they resemble Tonics (q. v.) in some respects; thus immediately after their administration a feeling of increased power is produced, which, however, is not permanent, and is almost always followed by a corresponding depression of vital power; their effects are, however, more immediate than those of tonics. Many of these agents, as, for example, alcohol and the ethers, are closely allied to narcotics, their secondary effect, if given in sufficiently large doses, being to produce sleep, and even coma. The following are the most important of the general stimulants. 1. *Alcohol*, in the various forms of spirits and wines. As a stimulant, alcohol is employed in medicine to support the vital powers in the advanced stages of fevers, particularly those of a low or typhous character; and it is of service in flatulent colic, in some forms or indigestion, in vomiting, and in fainting. Its almost universal use in inflammatory diseases occurring in persons of broken-down constitution, has recently been advocated by a special school, of which the late Dr. Todd may be considered the representative. In cases of severe uterine hæmorrhage and in some forms of fever, it may be given in very large quantity. According to Neligan, in the fever

which proved so fatal to the British Legion in Spain in the year 1835, some of the physicians prescribed as much as 32 ounces of Brandy (a pint and a half) in 24 hours.

2. *Ammonia*, either in the form of *Solution of Ammonia*, or *Liquor Ammonia*, or as *Carbonate of Ammonia*, is a general stimulant, whose action is rapid, but temporary. It is of special use in the advanced stages of continued fever, in the eruptive fevers when the rash has receded (especially in scarlatina), and in the later stages of pneumonia. It is the best internal stimulant to employ in profound intoxication, and in cases of poisoning by sedatives; and as an external stimulant, the vapor is inhaled in cases of fainting. The solution (which must not be confounded with the *Strong Solution of Ammonia*) may be given in doses from 5 to 30 minims, diluted with two ounces of water, mucilage, or any bland fluid. The *Carbonate* (formerly known as the sesquicarbonate, which, in reality, it is) may be given in doses varying from 3 to 10 grains in pills or in cold water. The *Aromatic Spirit of Ammonia* containing both ammonia and its carbonate, is an excellent and agreeable stimulant in fainting, hysteria, flatulent colic, &c., in doses of from half a drachm to a drachm, taken in water or camphor mixture. 3. *Cajeput Oil*, in doses of from 2 to 6 drops on a lump of sugar, or rubbed up with sugar, is a powerful diffusible stimulant, admirably suited for cases of flatulent distention of the stomach and intestines.

4. *Ether* (known also as *Sulphuric Ether*) acts as a general diffusible stimulant; but its effects, which are rapidly produced, are very transient. It is chiefly employed as a stimulant in spasmodic and nervous affections unaccompanied by inflammation, as 'in cramp of the stomach, in spasmodic or flatulent colic, in nervous palpitations, in hiccough, in nervous headache, during a paroxysm of spasmodic asthma, in aphonia, &c. It is also administered frequently with good effect in the advanced stages of fever, when the twitching of the muscles, known as *subsultus tendinum*, and hiccough are present; and as an immediate stimulant in fainting and asphyxia.'—Neligan's *Medicines*, &c., 6th ed., p. 452. It is usually given in doses of about a drachm in some aromatic water. To these more important stimulants may be added camphor, ginger, horse-radish, the preparations of lavender, of the mints, &c. It must not be forgotten that electricity, galvanism, and magnetic electricity operate on the animal system either as general or local stimulants, according to the manner in which they are applied. See ELECTRICITY, MEDICAL.

STING-FISH. See WEEVER.

STING RAY (*Trygon*), a genus of cartilaginous fishes, of the order *Raiæ* (see RAY), and family *Trygonidæ*. In this family, the tail is long and slender, the eyes on the upper (dorsal) aspect, and in the genus *Trygon* the tail is armed with a strong spine notched on both sides. The tail has either no fin, or a merely

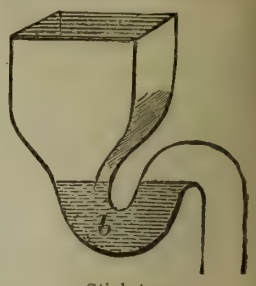
Sting Ray (*Trygon pastinaca*).

rudimental one. Only one species of S. R. occurs in the British seas (*T. pastinaca*), popularly known as the Fire Flaire. It is found in the Mediterranean, and thence to the northernmost parts of Europe. It resembles a skate in general appearance. The flesh is remarkable for its redness of color, and is not esteemed. The S. R. is dreaded from the power which it has of using its muscular and flexible tail as a weapon, twisting it round the object of attack, and inflicting severe lacerated wounds with the serrated spine. These wounds often cause great inflammation, whence a notion has been prevalent from ancient times that the sting is charged with venom; but of this there is no evidence. Other species of S. R. are plentiful in the warmer parts of the world, and they are everywhere dreaded. The spine is used by the savages of the South Sea Islands to point their spears.

STINKPOT, in Warfare, a Shell, often of earthenware, charged with combustibles, which, on bursting, emit a foul smell and a suffocating smoke. It is useful in sieges for driving the garrison from their defences; also in boarding a ship, for effecting a diversion while the assailants gain the deck. The stinkpot is a favorite weapon of the Chinese. Under the more elegant title of Asphyxiated Shell, the French and other modern nations have experimented considerably on this mode of harassing an enemy.

STINKSTONE, or SWINESTONE, a kind of marble or limestone remarkable for the fetid urinous odor which it emits when rubbed. It contains a little sulphur.

STINK-TRAPS, a name given to certain very useful forms of drain-openings, which, whilst allowing liquids to run down, prevent the escape of noxious gases. They are made of iron or earthenware, in a great variety of forms, but on one very simple principle, there being a curved or siphon pipe below the grating or grid (fig.), which always retains sufficient water, *b*, to prevent the outward passages of the gases.



Stink-trap.

STINK-WOOD (*Oreodaphne fœtida*), a tree of the natural order *Lauraceæ*, a native of the Cape of Good Hope, remarkable for the strong disagreeable smell of its wood, which, however, is hard, very durable, takes an excellent polish, and resembles walnut. It has been used in ship-building.

STINT. See SANDPIPER.

STI'PA. See FEATHER GRASS.

STIPE, in Botany, a term used to designate the stem of palms and tree-ferns.

STI'PEND, the provision for the support of the parochial clergy of the Church of Scotland. It consists of payments in money or grain, or both, made out of the teinds or tithes of their parishes. the Teinds (q. v.), originally the tenths of the produce of the lands drawn in kind, have become converted into separate estate, held under a liability for stipend. In a majority of cases, they have been purchased at a valuation by the owners of the lands to which they belong, stipends having first been 'modified' from them, and they are held under the burden of augmenting the minister's stipend to the extent of their value. Sometimes they have passed into the hands of titulars, i. e., grantees from the crown and their successors, or belong to colleges and hospitals, to all of whom payment of tithe is made by the proprietor of the lands according to a valuation or composition; and the teinds formerly held by bishops or other dignified clergy are in the hands of the crown.

In 1617, a commission was appointed by James VI. to modify stipends to the clergy from the parochial teinds. The provision was at first limited to a maximum of 10 chalders of victual or 1000 merks (£55, 11*s*. 1*d*.) *per annum*, and a minimum of five chalders or 500 merks (£27, 15*s*. 6*d*.); but the minimum was raised in 1649 to eight chalders, or three chalders and money for the other five, at a conversion not exceeding £100 Scots or beneath 100 merks for each chalder; and it has been the practice to allow a further sum to the minister to meet the expense of communion elements. The power of assigning, modifying, and localling stipends has, since the Union, been possessed by the judges of the Court of Session, sitting as a Court of Commission of Teinds. When the existing stipend of a clergyman is considered insufficient, and there remains any free teind (i. e., teind as yet unappropriated for stipend), the court have it in their power to award him out of it what augmentation they deem suitable. But by act 48 Geo. III. c. 138, no stipend can be augmented a second time till after the lapse of 20 years from a previous augmentation. The augmented stipend is modified in victual; but the minister receives it not in kind, but in value, according to the highest fiars (q. v.) prices of each year. By 50 Geo. III. c. 84, £10,000 annually was set apart from the revenue for the purpose of raising all stipends to £150, where the teinds of the parish did not provide that sum. Act 5 Geo. IV. c. 72 makes certain provisions out of the public revenue for those clergymen who have neither manse nor glebe, or who have a manse but no glebe, or a glebe but no manse, and whose stipends do not exceed £200 a year.

The terms at which stipend is payable are Whitsunday and Michaelmas. If the incumbent be admitted before Whitsunday, he is entitled to the whole year's stipend; and if his interest cease before that term, he has no claim to any part of it. If he is admitted between Whitsunday and Michaelmas, he is entitled to a half-year's stipend. If his interest cease between these terms, he or his representatives have right to a half-year's stipend; and if it cease after Michaelmas, to the whole year's stipend. No stipend is due till collation have taken place; and stipend continues due to a suspended clergyman. On the decease of a clergyman, a sum equal to a half-year's stipend is due to his executors, under the name of *ann* or *annat* (a word derived from the not altogether analogous *annatæ*, or first-fruits of the canon law), one half of which goes to the widow, and the other half to the chil-

dren or other next of kin, the whole passing to the next of kin where there is no widow. It is additional to the sum otherwise due to the incumbent; so that, if he survive Whitsunday, he will have half the year's stipend, and his executors will have the other half as *ann;* and if he survive Michaelmas, he will have the whole year's stipend, and an additional half-year's stipend will be due to the executors as *ann.* The stipend accruing during a vacancy was formerly at the disposal of the patron of the parish for pious purposes; but has been given by statutes 50 Geo. III. c. 84, and 54 Geo. III. c. 49, to the Ministers' Widows' Fund.

STIPULATION, in Roman Law, was an agreement attended with certain solemnities.—The word is used in English and Scotch Law only in a popular sense, to denote any distinct matter expressly agreed upon by the parties to an agreement or deed.

STI'PULE, in Botany, a leafy appendage at the base of the leaf-stalk in many plants. Sometimes the stipule is solitary; but frequently there are two, one on each side of the leaf-stalk. They are of very various form and character, often very dissimilar to the leaf with which they are connected. In some plants, they are large, enveloping the young leaf, but soon falling off; in many, they are deciduous; but in many they are as permanent as the leaf itself. Their presence or absence, their deciduous or persistent character, and other peculiarities which they exhibit, form distinctive characteristics not only of species and genera, but of natural orders. They are generally green, like leaves; but sometimes membranaceous. In some plants, they assume the form of spines; in *Cucurbitaceæ,* that of tendrils. Organs of the same nature with stipules appear at the base of the leaflets of some compound leaves.

STI'RLING, a market-town, river-port, and royal, parliamentary, and municipal burgh, capital of the county of the same name, stands on the south bank of the Forth, 29 miles north-east of Glasgow by railway. Like Edinburgh, to which city it bears, in its main features, a striking resemblance, it no doubt owes its origin to the strong natural fortress of its Castle Hill. From this Hill, covering the declivity which slopes north and eastward to the plain, extends the oldest part of the town, around which are numerous streets; while many villas have arisen in the environs. The Castle Hill, which rises gradually from the east and fronts the west, with a steep precipitous wall of basaltic rock, overlooks the beautiful and fertile *carse,* or flat, which lies along the banks of the Forth. Among the more prominent public buildings and institutions are the East and West Churches—the former erected by James IV. about 1494, the latter built at a later period; and 'Mar's Work,' an incomplete structure, built by the Earl of Mar, Regent of Scotland, who died in 1572, when the building was in progress. This architectural fragment is richly ornamented.

In the more ancient quarters, one or two pleasing specimens of old Scotch domestic architecture may still be seen. Of these, 'Argyle's Lodging,' with its pinnacled round towers and decorated windows, is the chief. It is now used as a military hospital. The town-house is surmounted with a spire, and has the old jail attached. It contains the jug or standard of dry measure which was given to the keeping of S. by the Scottish parliament; while Linlithgow is said to have received the firlot; Edinburgh, the ell, &c. The new jail is a handsome building. Cowan's Hospital, founded in 1639, is an object of interest. There are also an Athenæum, Corn Exchange, and numerous excellent schools. A magnificent art institute, called the Smith Institute, in honor of the founder, was opened in 1874. The importance of S. in early times was due to its situation and its defences. At the head of the navigation of the Forth, when there were no regular ferries, S. was the key to the Highlands, and the possession of its strengths and its means of communication between north and south was of the greatest importance. The town, besides, was strongly fortified both by nature and art. The ancient bridge of S., the age of which is unknown, but which was in existence in 1571, is composed of four arches, and was defended at each end by gates and towers. This bridge was until quite recent years, the only one by which wheeled carriages could cross the Forth. Vessels of 150 tons can reach the port of S.; but its commerce by river is now of less importance than before the days of railways.

S. is a central railway station, and the means of communication in every direction are ready and abundant. The rich agricultural, mining, and manufacturing districts around are to a great extent the basis of the prosperity of the town itself. Manufactures of ropes, malt, leather, soap, and mineral oils are carried on. The town unites with the the Dunfermline burghs in sending a member to the House of Commons. Pop. in 1881 of parl. burgh, 16,001; of town, 16,012.

S. (formerly *Stryvelyne,* or *Estrivelin*) is one of the most ancient and historically important towns of Scotland. It is of unknown antiquity; and there is no record from which the date of the foundation of even the castle can be determined. It must have been a frontier fortress from the earliest times. Alexander I. died in the castle in 1124. In the vicinity, the battle of Stirling was fought in 1297. See WALLACE. The town was taken by Edward I., after a siege of three months, in 1304. In the vicinity, at Bannockburn (q. v.), the famous battle of that name was fought in 1314. The castle was the birthplace of James II. and of James V. James III. built the Parliament House in the Castle, and otherwise improved and embellished the fortress.

James V. built the palace, the walls of which are profusely covered with grotesque ornamentation. In the older part of the Castle is the 'Douglas Room,' in which William, Earl of Douglas, was assassinated by James II. In 1651, after the battle of Dunbar, the castle was taken by Monk; and it withstood a siege by the Highlanders in 1745. The view from the towers of Stirling Castle is unsurpassed in beauty. Westward, the rich vale of Menteith stretches away to the Highlands, where Ben Lomond, Ben Venue, Ben A'an, and Ben Ledi close the scene. The glittering 'links' of Forth are seen in the Carse of Stirling, surrounded by fertile fields and luxuriant woods; the Abbey Craig, crowned by the Wallace Monument, rises boldly on the north; while on the east are seen the picturesque ruins of Cambuskenneth Abbey.

STI'RLINGSHIRE, a county of Scotland, forming the borderland between the Highlands and Lowlands of the country, is bounded on the N. by Perthshire and by the river and Firth of Forth. Area, 467 sq. m.; pop. in 1881, 112,443. A considerable part of S. is occupied by the carses of Stirling and Falkirk, which were formerly covered for the most part with unproductive moss. On the removal of the moss-soil, part of which was floated off into the Forth by the agency of running water, a rich clay-soil, of various depths, from a plough-furrow to 20, and even 30 feet, was reached, and is now cultivated with the most marked success. The chief elevation is Ben-Lomond (q. v.), in the northwest. The chief rivers are the Forth (q. v.), the Carron—navigable for small vessels to Carron-shore—and the Endrick. Loch Lomond (q. v.) is the only important lake in the county. S. is remarkable for its mineral stores, especially iron-stone, which is wrought on an extensive scale at Carron (q. v.).

Woollen goods, &c., are largely manufactured, especially at Alva, Bannockburn, and in the neighborhood of Stirling (q.v.). Of the area of 298,579 acres, there were in 1881, 114,191 acres under all kinds of crops, bare fallow, and grass. There were 30,922 under corn crops (2811 being under wheat); under green crops, 9998 (4658 in turnips); 23,663 under clover and grasses under rotation; 48,101 under permanent pasture and meadow. In the same year there were in the county 4778 horses, 28,897 cattle, 409,233 sheep, and 1682 swine. The valued rents in 1674 was £9042; in 1880–81, £406,573 (exclusive of canals and railways). The parliamentary constituency in the same year was 3399.

STI'RRUPS (Naval) are eyes of rope pendent from the yards, and supporting certain portions of the tackle connected with the management of the sails.

STITCH in the side is the popular and expressive name applied to the pain felt in pleurisy. It occupies a point or small spot on a level with, or just beneath the breast on the affected side; and patients state that they feel as if some sharp stabbing instrument were being driven in at that spot, whenever the act of inspiration goes beyond a certain limit. It is termed in French *Point de côté.* See PLEURISY. A simple modification of stitch is by no means uncommon, if a person take exercise shortly after partaking of a full meal. The pain in this case is seated lower in the side, and is usually removed by stooping. Hence the popular remedy for this pain is to make a cross upon the foot.

STI'TCHWORT (*Stellaria*), a genus of plants of the natural order *Caryophylleæ,* having a calyx of 5 leaves, 5 deeply-cloven petals, 10 stamens, 3 styles, and a many-seeded capsule opening

Greater Stitchwort (*Stellaria Holostea*).

with six teeth. The species are numerous, and several are very common in Britain, annual and perennial plants, with weak stems and white flowers, which in some are minute, and in others are large enough to be very ornamental to woods and hedge-banks, as in the Wood S. (*S. nemorum*) and the Greater S. (*S. Holostea*). To this genus the common Chickweed (q. v.). is now generally referred.

STI'VER, a coin of Holland, equivalent to a penny sterling, being the $\frac{1}{20}$th of a guilder or gulden. See FLORIN.

STOAT. See ERMINE.

STOCK-BROKER, or SHARE-BROKER, a person employed in buying and selling stock in the public home and foreign funds, also in stock or shares of joint-stock companies. In most of the principal towns stock exchanges are established, and the stock or share brokers are members of such exchanges, and are bound to transact business in terms of the rules and regulations of the exchange to which they belong. In London, in addition to ordinary brokers, there are what are called sworn brokers, who require a license from the city corporation, for which certain fees are exacted, before being entitled to transact business in the public funds. In the provincial exchanges, the brokers require no license, nor do they pay any fee to government or other authorities. The charge for brokerage or commissions varies from $\frac{1}{4}$ in consols to $\frac{1}{2}$ per cent. in railway stocks; the rates for shares being charged according to the amount of the share, and in accordance with a scale adopted by the stock exchanges.

STOCK, or STOCK GILLYFLOWER (*Matthiola*), a genus of plants of the natural order *Cruciferæ*, having cylindrical or compressed pods, and a stigma consisting of two upright appressed plates, the outer side of which often rises into a knob or horn. The species are herbaceous or half-shrubby, natives of the countries around the Mediterranean Sea, most of them thickly clothed with white or grayish stellate hairs; the flowers in racemes, and generally beautiful and fragrant. Some of the species have long been much cultivated, and many fine varieties have been produced by cultivation. *M. incana*, a very rare and even doubtful native of England, is probably the parent of the greater number of the cultivated kinds with hoary leaves, known as Brompton S., &c.; whilst those with smooth leaves, called Ten-week S., German S., &c., are referred to *M. annua*, *M. glabra*, and *M. fenestralis*, which, perhaps, are mere varieties of one species. The sandy shores of Wales and of Cornwall produce a species, *M. sinuata*, the large purple flowers of which are fragrant only at night—a characteristic also of several other species.

Stocks are always raised by gardeners from seed, which even the double kinds often produce, a multiplication of the petals having taken place without loss of the parts of fructification. Of the seedlings, however, some produce double, and others single flowers, so that only some gratify the cultivator. The hoary-leaved stocks are generally treated as biennials, although, in reality, they may almost be reckoned perennial; and it is not desirable that they should flower in the first year, as the plants become stronger when they remain without flowering till the second year, and produce richer racemes of flowers. The smooth-leaved stocks are treated as annuals.—The beautiful little annual called Virginian Stock does not belong to this genus, although it is of the same natural order. Its habit is indeed very different. It is *Malcolmia maritima*, and notwithstanding its popular name, is a native of the shores of the Mediterranean. It has become one of our most favorite flowers, almost rivalling mignonette, and is all the more esteemed because it grows well in the little garden-plots which are exposed to the smoke of towns.

STOCK-FISH, a commercial name of salted and dried cod and other fish of the same family, particularly the Ling, Hake, and Torsk (see these heads). The fish is cured as soon as possible after being caught. It is split up from head to tail, cleansed from all particles of blood by plentiful washings with salt water; a piece of the back-bone is cut away; and after the superfluous water has drained off, the fish are laid in long vats, covered with salt, and kept down by heavy weights. By and by, they are taken out, washed and brushed, and then exposed to sun and air on a sandy beach or upon the rocks. They are afterwards gathered into little heaps, and when they assume a fine whitish appearance, known as the *bloom*, they are considered ready for the market. Great quantities of stock-fish are thus prepared in the northern parts of the world, and are not only used in the countries which produce them, but are largely exported to more southern regions, where they are in great demand. The cod, ling, and hake fishery of Scotland is next in importance to its herring-fishery. In 1873, according to the Report of the Fishery Commissioners, the yield was 160,716½ cwts. of dried fish, besides 12,381½ barrels cured in pickle. The quantity exported was 70,101½ cwts. cured dried. The quantity of stock-fish cured on the more southern coasts of Britain is inconsiderable

STO'CKHOLM, the capital of Sweden, is situated at the eastern extremity of the Maelar Lake, in 59° 20′ N., and 18° 5′ E. long. The pop. was in 1880, 168,775. S., which is one of the most beatiful capitals of Europe, is built partly on the continent, and partly on nine holms, or islands, lying in the channel through which the Maelar Lake discharges its waters into the Baltic, about 36 miles distant. The Helge-aand, Stads, and Riddar holms, which formed the nucleus of the ancient city, founded in 1250 by Birgir Jarl, contain some of the finest public and private buildings, among which we may instance the royal palace, built in 1753, in the Italian style, and situated on a hill, commanding a view of the romantic shores of the lake. Near the palace, which possesses good antiquarian, numismatic, and other collections, a library, gallery of paintings, large gardens, &c., is the colossal statue of Gustavus III., on one of the fine quays, which skirt the chief harbor of S.; the cathedral, or St. Nicolai's; the Knight's Hall, with the adjoinging market, ornamented with the fine statue of Gustavus Vasa, the Council-house, the Riddarsholm Kirke, where all the kings of Sweden since Charles X. have been buried; &c. Among the other public buildings, the most noteworthy are the Observatory, the Church of St. James, the College of Surgery and the Opera-house, with the neighboring and corresponding palace, in the aristocratic quarter of Norrmalm, which, with the new parade-ground, its public gardens, and its fine wide and even streets, ranks as the handsomest part of the town.

The most picturesque of the nine islets of S. is the Södermalm, on whose steep sides the houses, connected more frequently by steps than roads, rise in terraced rows to the even summit, which is crowned by St. Catharine's Church. Numerous public gardens, summer palaces, and country-houses extend along the north-east shores of the lake, and on the margins of the Ladugaard's Holm, the central portions of which present a picturesque blending of rocks, wooded heights, and romantic glens. On this side of S. lies the famous Djurgaard, or Zoological Gardens, one of the finest public parks in Europe, which occupies a peninsula two miles long, and one mile wide, whose natural beauties have been judiciously aided by art. Stone and wooden bridges connect together the various islands of the town. The streets of the older quarters are narrow, crooked, and ill-paved; but in the better parts of the town there are fine straight streets and capacious squares and open places, with well-built stone houses; while in the suburbs the houses are mostly of wood. S. is the seat of the government, and of the chief courts of law and administration, the residence of the sovereign, and the place of assembly for the legislative chambers. It is the center of the literary and social activity of the country, and has numerous scientific, artistic, educational, and benevolent institutions.

In the immediate vicinity of S. are the Karlsberg Academy, for naval and military cadets; and the Ulriksdal Hospital, for invalided soldiers. No city has more picturesque environs, or more numerous public gardens and walks, than S.; while the many channels and canals connected with its large and commodious harbors facilitate traffic and intercommunication with the interior, and with foreign ports. S. is the principal emporium of Swedish commerce; iron, timber, and deal planks are its main articles of export; but it is also the center of an active trade in the various manufactures of the place—as, for instance, leather, cotton, woollen, and silk fabrics, glass and porcelain, iron and steel goods, steam-engines, &c., which it sends, together with the ordinary colonial and other imports, to all the other towns of Sweden.

STOCKING-FRAME. The machine with which stockings, singlet drawers, and other similar garments are woven, was first invented by William Lee of Woodbridge, Notinghamshire. At first, it was a very simple affair, but has now become extremely complicated, although the simple principle upon which it was first originated is retained as the essential. This can only be understood by reference to the art of knitting, which originated it. In knitting, only one thread is used, and this formed into a succession of loops on a knitting-needle; each of these loops, then, has in succession another loop passed through it by means of another

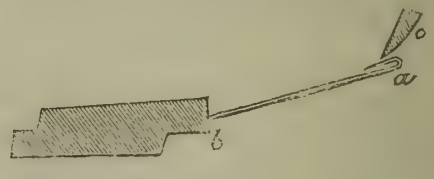


Fig. 1.

Fig. 2.

and similar needle, and this operation is carried on successively until the whole fabric is made.

In the stocking-frame, instead of one needle to hold the stationary loops while those of the moving row are being inserted, there are as many needles as there are to be loops in the breadth of the web, and these are so made as to alternately form and give off

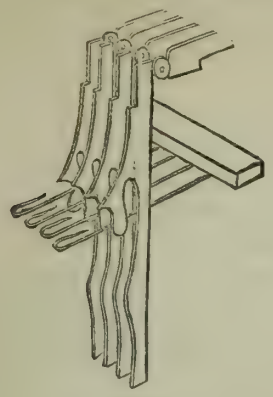

Fig. 3,

the loops. The form of this needle is shown in fig. 1, and fig. 2 shows a front view of its point, in order to exhibit a small indentation, *a*, into which the bent point of the needle *a* (fig. 1), is easily pressed. The other end of the needle is fixed into a small casting of tin, *b* (fig. 1), formed to fit into a frame, and be screwed tightly in, side by side with the rest of the needles. Between the needles are placed thin plates of lead or pewter, called *sinkers*

Fig. 4.

(fig. 3), in two rows; in one row, the sinkers move freely on an axis (fig. 3); in the other, they are all fixed to a bar, and move with it. The object of the loose ones, or *jack-sinkers*, is to make loops by pressing the thread down between the needles, as shown in fig. 4 and 5 at *a*. The other row on the bar, or *lead-sinkers*, are brought down, so as to press simultaneously on the hooks of

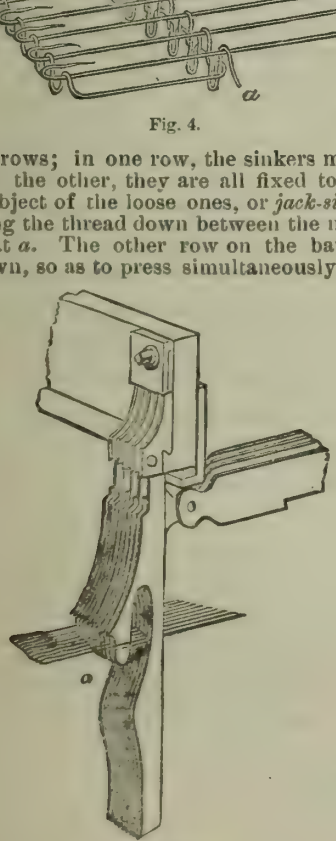

Fig. 5.

the needles, and press their points down into the little depression *a* (fig. 2), so that they will pass through the loops without catching one way, and take them up when opened and drawn in the contrary direction.

The point of the lead-sinker is seen in fig. 1, *c*. These are the essential parts of a stocking-frame, which contains so vast a number of needles and sinkers, and such nice mechanical arrangements for giving them their regular movements, that few machines have so complicated an appearance to the observer; and any attempt to extend this description, would only serve to puzzle rather than explain.

STOCKINGS. See HOSIERY.

STO'CKPORT, a town of England, in the county of Chester, on the river Mersey and 6½ miles south-east of Manchester by railway. It is of great antiquity, but its prosperity is of modern date. S. has extensive manufactures of cottons, woollens, silks, machinery, brass and iron goods, shuttles, and brushes. Pop. (1871) 53,014; (1881) 59,544. S. returns two members to parliament.

STOCKS, an apparatus of wood, much used in former times in England for the punishment of petty offenders. The culprit was placed on a bench, with his ankles fastened in holes under a movable board, and allowed to remain there for an hour or two. The period of their first introduction is uncertain, but in the second Statute of Laborers, 25 Edw. III. (1350), provision is made for applying the stocks to unruly artificers; and in 1376, the Commons prayed Edward III. that stocks should be established in every village. Each parish had in later times its stocks, usually close to the churchyard, but sometimes in a more retired spot;

Stocks.

and in some country places they are still to be seen, and not altogether disused. Combined with the stocks was often a whipping-post for the flagellation of vagrants.

STOCKS. See FUND.

STO'CKTON, a town and port of entry of California, U. S., on Stockton Channel, near San Joaquin, 130 miles east-south-east of San Francisco. It is an important commercial point, and the entrepôt of the southern gold mines. It has three newspapers, several churches, a hospital, and pop. (1870) 10,066; (1880) 20,287.

STO'CKTON-ON-TEES, a municipal borough and seaport in the county of Durham, 11 miles east-north-east of Darlington, on the left bank of the Tees. The broad and handsome High Street is nearly a mile in length, and from it several minor streets diverge at right angles. A new town, known as South Stockton, has sprung up within the last few years on the right bank of the river. The town contains two churches, a Roman Catholic chapel built by Pugin, several dissenting chapels, an athenæum, and other important edifices. The Stockton Races, of some mark in the sporting world, are held here annually. Ship-building, chiefly in iron, is carried on to a great extent; and blast-furnaces, foundries, engine-works, and extensive potteries and iron-works are in operation. Sail-cloth, ropes, linen, and diapers are manufactured; and there are breweries, corn-mills, and spinning-mills. The exports are chiefly iron and earthenware; the imports are corn, timber in deals, spars, &c., and bark. In 1880. 827 foreign and coasting vessels, of 155,632 tons, entered, and 813, of 167,143 tons, cleared the port. The town is connected with the whole railway system of England and Scotland by the North-eastern Railway Company's branches, and there are two stations here. The Stockton and Darlington Railway, the first in the United Kingdom to commence passenger traffic, was opened for the double purpose of the conveyance of passengers and goods, September 27, 1825. At S. the Tees is navigable for vessels of large tonnage; by a cut, by which a bend of the river is avoided, the town is brought 3 miles nearer the sea; the navigation of the river has been much improved, and great facilities for an extensive trade provided. Pop. of parl. borough, (1881) 55,446.

S. suffered severely from the incursions of the Scots in the early part of the 14th c., but even at that time it enjoyed considerable trade. It was taken for the Parliament in 1644, and totally destroyed by the Roundheads in 1652. At the Restoration it had become so poor a place that it contained only 120 houses, and most of these were built of clay.

STOICS, the name for the sect of ancient moralists opposed to the Epicureans in their views of human life. The Stoical system dates from the end of the 4th c. B.C.; it was derived from the system of the Cynics, whose founder, Antisthenes, was a disciple of Socrates. Indeed, the doctrines, but still more the manner of life, and most of all the death, of Socrates, were the chief foundations of the Stoical philosophy.

The founder of the system was ZENO, from Cittium in Cyprus (he lived from 340—260 B.C.), who derived his first impulse from Crates the Cynic. He opened his school in a building or porch, called the *Stoa Pœcile* ('Painted Porch') at Athens, whence the origin of the name of the sect. Zeno had for his disciple CLEANTHES, from Assos in the Troad (300—220 B.C.), whose *Hymn to Jupiter* is the only fragment of any length that has come down to us from the early S., and is a remarkable production, setting forth the unity of God, his omnipotence, and his moral government.

CHRYSIPPUS, from Soli in Cilicia (280—207 B.C.), followed Cleanthes, and, in his voluminous writings, both defended and modified the Stoical creed. These three represent the first period of the system. The second period (200—50 B.C.) embraces its general promulgation, and its introduction to the Romans. Chrysippus was succeeded by ZENO of Sidon, and DIOGENES of Babylon; then followed ANTIPATER of Tarsus, who taught PANÆTIUS of Rhodes (died 112 B.C.), who, again, taught POSIDONIUS of Apamea, in Syria. (Two philosophers are mentioned from the native province of St. Paul, besides Chrysippus—Athenodorus, from Cana in Cilicia; and Archedemus, from Tarsus, the apostle's birthplace. It is remarked by Sir A. Grant, that almost all the first S. were of Asiatic birth; and the system itself is undeniably more akin to the oriental mind than to the Greek.) Posidonius was acquainted with Marius and Pompey, and taught Cicero; but the moral treatise of Cicero, *De Officiis*, is derived from a work of Panætius. The third period of Stoicism is Roman. In this period we have Cato the Younger, who invited to his house the philosopher Athenodorus; and, under the Empire, the three Stoic philosophers whose writings have come down to us—SENECA (6 B.C.—65 A.D.), EPICTETUS (60—140 A.D.), who began life as a slave, and the Emperor MARCUS AURELIUS ANTONINUS (121—180 A.D.). Stoicism prevailed widely in the Roman world, although not to the exclusion of Epicurean views.

The leading Stoical doctrines are given in certain phrases or expressions, as 'Life according to Nature,' the ideal 'Wise Man,' 'Apathy,' or equanimity of mind, the power of the 'Will,' the worship of 'Duty,' the constant 'Advance' in virtue, &c. But perspicuity will be best gained by considering the *Moral* system under four heads—the Theology; the Psychology or theory of mind; the theory of the Good or human happiness; and the scheme of Virtue or Duty.

I. Their Theological doctrines comprehended their system of the Universe, and of man's position in it. They held that the Universe is governed by one good and wise God, together with inferior or subordinate deities. God exercises a moral government; under it the good are happy, while misfortunes happen to the wicked. According to Epictetus, God is the father of men; Antoninus exults in the beautiful arrangement of all things. They did not admit that the Deity intermeddled in the smaller minutiæ; they allowed that omens and oracles might be accepted as signs of the foreordained arrangement of God. They held this foreordination even to the length of fatalism, and made the same replies, as have been given in modern times, to the difficulty of reconciling it with Free-will, which in their system was unusually prominent.

As to the existence of evil, they offered explanations such as the following: God is the author of all things except wickedness; the very nature of good supposes its contrast evil, and the two are inseparable, like light and dark, which may be called the argument from Relativity; in the enormous extent of the Universe, some things must be neglected; when evil happens to the good; it is not as a punishment, but as connected with a different dispensation; parts of the world may be presided over by evil demons; what we call evil may not be evil.

Like most other ancient schools, the S. held God to be corporeal like man; Body is the only substance; nothing incorporeal could act on what is corporeal; the First Cause of all, God or Zeus, is the primeval fire, emanating from which is the soul of man in the form of a warm ether.

It is for human beings to recognize the Universe as governed by universal Law, and not only to raise their minds to the comprehension of it, but to enter into the views of the Creator, who must regard all interests equally; we are to be, as it were, in league with him, to merge self in the universal Order, to think only of that, and its welfare. As two is greater than one, the interests of the whole world are infinitely greater than the interests of any single being, and no one should be satisfied with a regard to anything less than the whole. By this elevation of view, we are necessarily raised far above the consideration of the petty events befalling ourselves. The grand effort of human reason is thus to rise to the abstraction or totality of entire Nature; 'no ethical subject,' says Chrysippus, 'could be righly approached except from the preconsideration of entire Nature, and the ordering of the whole.'

As to Immortality, the S. precluded themselves, by holding the theory of the *absorption* of the individual soul at death into the divine essence; but, on the other hand, their doctrine of advance and aspiration is what has in all times been the main natural argument for the immortality of the soul. For the most part, they kept themselves undecided as to this great doctrine, giving it as an alternative, reasoning as to our conduct on either supposition, and submitting to the pleasure of God in this as in all other things.

In arguing for the existence of Divine power and government, they employed what has been called the argument from Design, which is as old as Socrates. Man is conscious that he is in himself an intellectual or spiritual power, from which, by analogy, he is led to believe that a greater power pervades the universe, as intellect pervades humanity.

II. Next, as to the Constitution of the Mind. We have bodies like animals, but reason or intelligence like the gods. Animals have instinctive principles of action; man alone has a rational, intelligent soul. According to Antoninus, we come into contact with Deity by our intellectual part, and our highest life is thus the divine life.

But the most important Stoical doctrine respecting the nature of man is the recognition of Reason as a superior power or faculty that subordinates all the rest—the governing intelligence. (Very nearly the same phraseology is used by Bishop Butler in setting forth the supremacy of Conscience.) This, however, is not a mere intellectual principle, but an active force, uniting intellect and will. The bodily sensibilities are opposed to this higher Reason and Will, which, however, is strong enough to control them. Another way of expressing the same view was the power of the Mind over the Body, which was dwelt upon by Epictetus in the most exaggerated form. The introduction of so glaring a mistake, as that sickness may effect the body without enfeebling the mind, could only end in practical failures, or else in contradiction.

In order to maintain their contrast with the Epicureans, the S. said that pleasure and pain are not principles of Nature; by which they must have meant that humanity is not in fact, at least exclusively, governed by these, and that, in the regenerated man, they are not governing principles at all. Now, it is true, and a truth important for many practical purposes, that we are sometimes impelled to action without reference to our pleasures and pains; our habits often exemplify this state; it is still better shown in what are called 'fixed ideas,' as in involuntary imitation and sympathy. But these are exceptions; and any system that sets itself against the main fact, that pleasure and pain are the great moving forces of mankind, must somewhere or other contradict itself.

In Seneca, we find something very closely approaching to the Christian doctrine of the corruption of human nature. The littleness of humanity was a favorite theme of Antoninus, and naturally followed from the Stoical mode of contemplating the Universe at large.

The doctrine called the Freedom of Will may be said to have originated with the S., although with them it was chiefly a rhetorical mode of expressing the dignity of the Wise Man, and his power of rising superior to circumstances.

To prepare the way for the Stoical precepts, Epictetus distinguished between things in our power and things not in our power. The things in our power are our opinions and notions about objects, and all our affections, desires, and aversions; the things not in our power are our bodies, wealth, honor, rank, authority, &c., and their opposites. The application is this: wealth and high rank may not be in our power, but we have the power to form an *idea* of these—namely, that they are unimportant, whence the want of them will not grieve us. A still more pointed application is to death, whose force is entirely in the idea.

III. We must consider next the Stoical Theory of Happiness, or rather of the Good, which with them was not identified with happiness. They began by asserting that happiness is not necessary, and may be dispensed with, and that pain is no evil, which, however, if followed consistently, would dispense with all morality and all human endeavor. Substantially and practically, they held that pains are an evil, but, by a proper discipline, may be triumphed over. They disallowed the direct and ostensible pursuit of pleasure as an end (the point of view of Epicurus), but allured their followers partly by promising them the victory over pain, and partly by certain enjoyments of an elevated cast that grew out of their plan of life.

Pain of every kind, whether from the casualties of existence, or from the severity of the Stoical virtues, was to be met by a discipline of endurance, a hardening process, which, if persisted in, would succeed in reducing the mind to a state of Apathy or indifference. A great many reflections were suggested in aid of this

education. The influence of exercise and repetition in adapting the system to any new function, was illustrated by the Olympian combatants, and by the Lacedæmonian youth who endured scourging without complaint. Great stress was laid on the instability of pleasure, and the constant liability to accidents; whence we should always be anticipating and adapting ourselves to the worst that could happen, so as never to be in a state where anything could ruffle the mind. It was pointed out how much might still be made of the worst circumstances—poverty, banishment, public odium, sickness, old age—and every consideration was advanced that could 'arm the obdurate breast with stubborn patience, as with triple steel.'

It has often been remarked that such a discipline of endurance was peculiarly suited to the unsettled condition of the world at the time, when any man, besides the ordinary evils of life, might in a moment be sent into exile, or sold into slavery. Moreover, it is a discipline adapted to a certain class of dispositions existing in all ages—the men that prefer above all things 'equanimity' of mind, and would rather dispense with great occasional pleasures than risk their state of habitual composure.

Next to the discipline of endurance, we must rank the complacent sentiment of Pride, which the Stoic might justly feel in his conquest of himself, and in his lofty independence and superiority to the casualties of life. The pride of the Cynic, the Stoic's predecessor, was prominent and offensive, showing itself in scurrility and contempt towards everybody else; the Stoical pride was a refinement upon this, but was still a grateful sentiment of superiority, which helped to make up for the surrender of indulgencies. It was usual to bestow the most extravagant laudation on the 'Wise Man,' and every Stoic could take this home to the extent that he considered himself as approaching that great ideal.

The last and most elevated form of Stoical happiness was the satisfaction of contemplating the Universe and God. Epictetus says that we can discern the providence that rules the world, if we possess two things—the power of seeing all that happens with respect to each thing, and a grateful disposition. The work of Antoninus is full of studies of Nature in the devout spirit of 'passing from Nature to Nature's God;' he is never weary of expressing his thorough contentment with the course of natural events, and his sense of the beauties and fitness of everything. Old age has its grace, and death is the becoming termination. This high strain of exulting contemplation reconciled him to that complete submission to whatever might befall, which was the essential feature of the 'Life according to Nature.'

IV. The Stoical theory of Virtue is implicated in their ideas of the Good, now described.

The fountain of all virtue is manifestly the life according to nature, as being the life of subordination of self to more general interests—to family, country, mankind, the whole universe. If a man is prepared to consider himself absolutely nothing in comparison with the universal interest, and to regard it as the sole end of life, he has embraced an ideal of virtue of the loftiest order. Accordingly, the S. were the first to preach what is called 'Cosmopolitanism;' for although, in their reference to the good of the whole, they confounded together sentient life and inanimate objects—rocks, plants, &c., solicitude for which was misspent labor—yet they were thus enabled to reach the conception of the universal brotherhood of mankind, and could not but include in their regards the brute creation. They said: 'There is no difference between Greeks and Barbarians; the world is our city.' Seneca urges kindness to slaves, for 'are they not men like ourselves, breathing the same air, living and dying like ourselves?'

The Epicureans declined, as much as possible, interference in public affairs, but the Stoical philosophers all urged men to the duties of active citizenship. Although there had been many good and noble men among the pagans, yet positive beneficence had not been preached as a virtue before the Stoics. They adopted the four Cardinal Virtues (Wisdom, or the Knowledge of Good and Evil; Justice; Fortitude; Temperance) as part of their plan of the virtuous life, the life according to nature. Justice, as the social virtue, was placed above all the rest. But most interesting to us are the indications of the idea of Beneficence. Epictetus is earnest in his exhortations to forgiveness of injuries. Antoninus often enforces the same virtue, and suggests considerations in aid of the practice of it; he contends as strongly as Butler and Hume for the existence of a principle of pure, that is, unselfish, benevolence in the mind, in other words, that we are made to advance each other's happiness.

There is also in the Stoical system a recognition of duties to God, and of morality as based on piety. Not only are we all brethren, but also the 'children of one Father.'

The extraordinary stress put upon human nature by the full Stoic ideal of submerging self in the larger interests of being led to various compromises. The rigid following out of the ideal issued in one of the Paradoxes, namely, that all the actions of the wise man are equally perfect, and that, short of the standard of perfection, all faults and vices are equal; that, for example, the man that killed a cock without good reason was as guilty as he that killed his father. This has a meaning only when we draw a line between spirituality and morality, and treat the last as worthless in comparison of the first. The later S., however, in their exhortations to special branches of duty, gave a positive value to practical virtue, irrespective of the ideal.

The idea of Duty was of Stoical origin, fostered and developed by the Roman spirit and legislation. The early S. had two different words for the 'suitable' (*kathekon*) and the 'right' (*katorthoma*); although it is a significant circumstance that the 'suitable' is the lineal ancestor of our word 'duty' (through the Latin *officium*).

It was a great point with the Stoic to be conscious of 'advance,' or improvement. By self-examination, he kept himself constantly acquainted with his moral state, and it was both his duty and his satisfaction to be approaching to the ideal of the perfect man. When renouncing the position of 'wise,' he yet claimed to be advancing. This idea, familiar to the modern world, was unknown to the ancients before the Stoics. It is very illustrative of the unguarded points and contradictions of Stoicism, that contentment and apathy were not to permit grief even for the loss of friends. Seneca, on one occasion, admits that he was betrayed by human weakness on this point. On strict Stoical principles, we ought to treat the afflictions and the death of others with the same frigid indifference as our own; for why should a man feel for a second person *more* than he ought to feel for himself, as a mere unit in the infinitude of the Universe? This is the contradiction inseparable from any system that begins by abjuring happiness as the end of life. We may be allowed to regard our own happiness as of no importance, but if we apply the same measure to happiness in general, we are bereft of all motives to benevolence; and virtue, instead of being set on a loftier pinnacle, is left without any foundation.

The Stoical system has largely tinctured modern ages, in spite of its severity. It has always had a charm as an ideal, even when men were conscious of not realizing it. It may be still considered as a grand experiment in the Art of Living, from which valuable lessons have resulted; just as a believer in Alchemy, or in the Perpetual Motion, might make useful experimental discoveries. The limitation of wants, the practice of contentment, the striving after equanimity, the hardening of one's self against the blows of fortune, are all familiar to the moralists of later ages. A qualified form of the subordination of self to the general welfare, belongs to the modern theories of virtue.

The chief ancient authorities on the Stoics are the writings of Epictetus, Marcus Antoninus, and Seneca, themselves Stoical philosophers together with notices occurring in Cicero, Plutarch, Sextus, Empiricus, Diogenes, Laertius, and Stobæus. The completest modern account of the system occurs in Zeller's *Philosophie der Griechen*, vol. iii. See also Sir Alexander Grant in the *Oxford Essays* for 1858; and *Stoicism*, by Rev. W. W. Capes (1880).

STOKE-UPON-TRENT, a municipality, parliamentary borough, and manufacturing town of Staffordshire, 145 miles from London by the London and North-western Railway. The 'district' of S. consists of the parish of S., is familiarly named the 'Potteries,' and contains the towns of Burslem, Hanley, Lane-End (with Longton), Stoke, and Tunstal Court. The town of S. is regularly built. Its church, an edifice in modern Gothic, has a tower 112 feet high. The earthenware manufactures of the parish of S. are carried on in about 200 factories. In the vicinity are coal-mines. Pop. of municipal borough (1871) 15,144; (1881) 19.263; of parliamentary borough, including the Potteries, which sends two members to the House of Commons (1871) 130,575; (1881) 152,457.

STOKES, GEORGE GABRIEL, one of the greatest living mathematicians and natural philosophers in Europe, was born, in 1819, at Skreen, County Sligo, Ireland; educated at the school of the Rev. R. H. Wall, D.D., Dublin; afterwards at the Bristol College. He entered Pembroke College, Cambridge, in 1837; graduated in 1841, as Senior Wrangler, and First Smith's Prizeman; became Fellow of Pembroke in the same year; and was elected, in 1849, to fill, as one of the worthiest of Newton's successors, the Lucasian Chair of Mathematics in Cambridge. In 1854, he was appointed Secretary to the Royal Society.

He is best known, popularly, by his beautiful discovery of Fluorescence (see PHOSPHORESCENCE). His paper *On the Change of the Refrangibility of Light*, is printed in the *Philosophical Transactions* for 1852—1853. His recent important physiological application of optical methods to the study of the oxidation of the blood, is noticed under SPECTRUM. But to mathematicians and natural philosophers, S. is known by a number of admirable papers in the *Cambridge Philosophical Transactions*, the *Cambridge and Dublin Mathematical Journal*, and the *Philosophical Magazine*. In them he has greatly extended and improved the mathematical treatment of questions connected with the distortion of elastic solids, the motion of waves in water, the undulatory theory of light, the summation of series, the internal friction of fluids, &c. Another

excellent work by S. is his *Report on Double Refraction*, in the British Association Reports for 1862. Lectures on Solar Physics were published in *Nature* in 1881. He was president of the British Association in 1869; and in 1871 the University of Edinburgh gave him the degree of LL.D.

STOLBERG, CHRISTIAN, COUNT VON, a German poet, born at Hamburg, October 15, 1748. He belonged to one of the oldest German families, originally of Thuringia, and which is mentioned in authentic documents of the 11th century. S. studied at Göttingen from 1769 to 1774, where he was one of a distinguished literary circle in North Germany, embracing Boje, Bürger, Miller, Voss, Hölty, and Leisewitz. In 1777, he married Luise, Countess of Reventlow, whom he had previously celebrated in his verses; and after 1800, lived apart from public life on his estate of Windebye, near Eckernförde in Slesvig, where he died January 18, 1821. As a poet, he was inferior in genius to his younger brother, but his pictures of family life are very fine. His principal works are *Gedichte* (Leip. 1779); *Gedichte aus dem Griechischen* (Hamb. 1782); *Schauspiele mit Chören* (Leip. 1787); and *Vaterländische Gedichte* (along with his brother; Hamb. 1815).

STOLBERG, FRIEDRICH-LEOPOLD, COUNT VON, younger brother of the preceding, was born at Bramstedt, November 7, 1750, studied at Halle and Göttingen, and after a visit to Switzerland and Italy, in the course of which he made the acquaintance of Goethe at Frankfurt, and of Lavater at Zürich, he became, in 1777, minister-plenipotentiary of the episcopal Prince of Lübeck at the court of Denmark. S. filled various other official situations in the course of his public life; but becoming a convert to Roman Catholicism, he resigned all his employments, and henceforth lived mainly in the society of his co-religionists. The causes that led him to take a step which lost him many old and dear friends, were partly the theological strifes between the Rationalists and orthodox Lutherans in Holstein—the country where he mostly resided, and partly his study of the controversial works of the Catholic writers during a second visit to Italy in 1790—1791. He died at Sondermühlen, near Osnabrück, December 5, 1819. S. is a superior poet to his elder brother. There is greater boldness in his ideas and imagery, and he displayed a wonderful facility in versification. We have from him specimens of all sorts of poetry, songs, odes, elegies, metrical romances, satires, descriptive verse, and dramas, which are contained in the *Werke der Brüder Stolberg* (22 vols., Hamb. 1821—1826). See *Friedr.-Leopold, Graf zu Stolberg*, by Nicolovius (Mainz, 1846). A very good account of S.'s change of faith, and of that literary circle of North Germany in which he moved until his conversion, will be found in a book called *Entiner Skizzen* (Sketches of Entin), by Wilhelm von Bippen (Weimar, 1862).

STOLE (Gr. *stolé*, Lat. *stola*, a robe) is the name of one of the sacred vestments used in the Latin Church, and with some modification in the Greek Church also. It originated in a wide and flowing robe of linen, called also *orarium*, which hung from the shoulder, and which had a narrow embroidered border of a different color, as we learn from St. Ambrose's sermon on the death of Satyrus (n. 43), and from Jerome's letter to Nepotianus (Ep. 52). The present stole seems to be the traditionary representative of the embroidered border of the orarium in the Roman Catholic Church, and consists of a narrow band of silk or precious stuff, edged and fringed with gold or embroidery. It is worn over the shoulders by priest and deacons, but in a different fashion —the former wearing it over it both shoulders, with the ends hanging in front, or crossed upon the breast; the latter carrying it only from the left shoulder to the right side, where the pendent ends are fastened. In the Eastern Church the stole is worn pendent, over both shoulders by priests, over the left shoulder only by deacons. The stole is worn at mass, and in the administration of sacraments, in certain blessings, and in more solemn forms of preaching. It is also used, in some cases, as a symbol of jurisdiction, in which sense it is constantly worn by the pope, even when not officiating; and there is a very remarkable usage in Italy and other Catholic countries, illustrative of the same principle as to jurisdiction, of the parish priest, after he has administered extreme unction to a sick person, *leaving the stole upon the foot of the bed, not to be withdrawn until the death or recovery of the invalid*. Like the other sacerdotal vestments, the stole must be blessed by a bishop, or a priest delegated by a bishop. In the English Church the stole is now generally used by the clergy, and is worn with the same difference by priests and deacons. In the case of dignitaries, doctors, and chaplains of noblemen or bishops, it is worn in the form of a scarf. The use of the stole in the English Church appears to rest only upon ancient custom, as it is not specified in any rubric or canon. It is usually of black silk, fringed at the ends, with sometimes crosses embroidered.

STOLEN GOODS, in point of Law, stand in this situation in England: a *bonâ fide* purchaser of such goods, who has not bought them in market overt, is bound to restore them to the true owner; but if the goods are sold in market overt, the purchaser is entitled to keep them, unless the owner has duly prosecuted and convicted the thief. Market overt means the open market in towns and places where a legal market is held, and the old doctrine was, that as all sales were conducted by exposure of goods in an open place, the owner of the lost goods was likely to find them easily by going to the nearest market—a doctrine which is now quite inapplicable to modern habits. In the City of London every shop is held to be a market overt within the above rule, but this only applies to the City proper, and not the suburbs and western parts of the metropolis. The above rule, as to stolen goods, does not apply to valuable securities which are stolen, if the security has been paid or discharged *bonâ fide* by the person liable, or if the security is a negotiable instrument, and it have been *bonâ fide* transferred or delivered for a just and valuable consideration, without any notice, and without any reasonable cause to suspect that the same had been obtained by felony or misdemeanor. The law is obviously harsh as regards owners, for a man who has had the misfortune to have his goods stolen, must go to the further loss and expense of prosecuting the thief before he can recover them.—In the law of Scotland, it is otherwise. The owner has not only an action against the thief, but against third parties, whether they have bought them or taken them in pledge *bonâ fide* or not. But as to bank-notes, and bills payable to bearer, or blank indorsed, the property in these passes with the possession, and the real owner cannot vindicate them against one who has *bonâ fide* acquired them in the course of trade. As to giving reward for recovery of stolen goods, see REWARD, also RESTITUTION.

STOLP, a garrisoned town of Prussia, chief town of a circle in the province of Pommern, is situated on the river Stolp, about 15 miles from its mouth, and 40 north-east of Köslin. S., which is composed of an old and new town, with four suburbs, has a castle, 4 churches (one of which, the *Marienkirche*, built in 1311, has a tower nearly 190 feet high), a hospital for invalids, amber and other manufactures, and an active general trade. Pop. (1880) 21,591.—At the mouth of the river, lies Stolpmünde (pop. 1118), the port of S., which carries on some shipbuilding and commerce.

STOMACH. The Anatomy and Physiology of this organ are treated of in the article DIGESTION (q. v.).

STOMACH, DISEASES OF. In the discussion of the diseases of any organ, it is customary to begin with the consideration of its inflammation. In the stomach, however, acute *gastritis*, or inflammation of the mucous membrane of that organ, is so rare a disease, except as a result of the administration of an irritant poison, that it might almost pass unnoticed. Thus Louis states that during six years' experience at La Charité (one of the leading Parisian hospitals), in which he made notes of 6000 cases of disease, and 500 dissections, he did not meet with a single case of fatal idiopathic (or spontaneous) gastritis. The simple fact, however, that this disease is almost always the result of poison, gives it a special interest, and renders it especially necessary that the physician should be so thoroughly acquainted with its symptoms, as to be able with certainty to detect it, and thus to be led to investigate its cause.

The symptoms which indicate that an irritant poison has been received into the stomach, are a gradually increasing sensation of uneasiness or heat, which shortly assumes an acute burning character in the epigastric region. This pain is accompanied with vomiting, which becomes increasingly frequent as the pain augments, and often with hiccup. There is usually extreme tenderness on pressure, and the patient bends his body forward to relax the muscular tension. During the accession of these symptoms, there is a marked degree of excitement, as indicated by the acceleration of the pulse and breathing, and the heat of the skin. This condition is, however, soon exchanged for one of prostration. The skin becomes cold and clammy, the pulse thready and feeble, and the breathing catching and intermittent; until finally, after a variable period of exhaustion, the patient sinks, usually retaining his mental faculties to the last. Although the above-described symptoms are always more or less present, each irritant poison occasions some special symptom, and some characteristic lesion; and the period at which death ensues varies for different poisons. Hence, quite apart from the results of analysis, a fair conjecture can usually be made as to the individual poison which has been administered.

Sub-acute gastritis is by no means a rare affection, and it occurs in two distinct forms—'one in which the malady is caused by a constitutional state, the effects of which are shown in a variety of other organs, as well as in the stomach; another in which it is due to causes connected chiefly or exclusively with this organ, which is submitted to an irritative process somewhat analogous to that typified by the gastritis of irritant poisoning.'—Brinton, *On Diseases of the Stomach*, 1859, p. 101. The first of these forms is well illustrated in certain cases of scarlatina, in which, if death takes place between the third and seventh day of the disease, distinct marks of inflammation are seen in the stomach,

The other variety, which is often of a chronic form, is best seen in cases of delirium tremens; the affection being sub-acute or chronic, according as it has been produced by a single prolonged debauch, or by a protracted habit of drinking spirits; the patient's final malady being induced by a deficiency of food, or the want of the ordinary stimulant. Purely chronic inflammation may be induced by various causes, of which the most common are the abuse of alcoholic drinks, habitual excess in eating, the eating of indigestible food, and the excessive use of irritating medicines.

The treatment of gastritis varies so much with each individual case, that we shall only lay down a few general principles. The first point is the removal of the cause; to be attempted in cases of irritant poisoning, either by the removal of the poison (by the stomach-pump or emetics, as, for example, sulphate of zinc), or by its neutralization by means of an antidote. In very severe cases, leeches may be applied to the epigastrium; but counter-irritants, such as turpentine on a hot moist flannel, or mustard-poultices, are generally of more service. Continuous fomentation with water, as hot as can be borne, often gives great relief; while at the same time iced water, or small lumps of ice swallowed whole, usually relieve the thirst and mitigate the pain. Enemata of purgative materials, if the bowels are constipated, or of a soothing character (as thirty drops of laudanum in a little starch or gruel), if the bowels are irritable, may be prescribed with advantage. When the stomach begins to be able to retain food, it must be given in the form of a bland liquid, in small doses, at distant intervals. Chronic gastritis must be treated in much the same manner as Indigestion (q. v.). The most essential point of treatment is the due regulation of the diet.

Ulcer of the stomach is the most important of the idiopathic diseases of that organ, both from its frequency, from the facility with which it may be detected during life, from the fact that at any period of its protracted course it may prove suddenly fatal, and from its being usually curable. The first and most characteristic symptom of this disease is pain, which commences as a mere dull feeling of weight or tightness, then gradually augments into a burning sensation, and at last assumes a gnawing character, and occasions a kind of sickening depression. This pain comes on in from two to ten minutes after the ingestion of food, and lasts for an hour or two; vomiting often ensues, after which the pain ceases. The place of its most common appearance and greatest intensity is the center of the epigastric region, or slightly below the free end of the ensiform cartilage of the sternum; and the painful spot is usually of a circular form, with a diameter varying from one to two inches. The pain in this region is succeeded, in the course of a few weeks, by a gnawing pain in the back, ranging in position from the eighth dorsal to the second lumbar vertebra, and most commonly lying between the two shoulder-blades. The pain in both the epigastric and the dorsal region is almost always much increased by pressure; it is also specially affected by certain kinds of food and drink, being increased by the ingestion of hard and indigestible substances, and lessened by a bland and pulpy diet. As a general rule, the pain is aggravated by tea, beer, and hot food; although exceptions occasionally occur.

The next symptom in this disease is vomiting or regurgitation, expelling the food previously taken or a glairy alkaline fluid. The vomiting usually occurs when the pain is most intense, and is a dangerous symptom, since it tends to starve the patient, and to increase the fatigue of an already weakened frame. At this stage, the disease is sometimes terminated by the occurrence of perforation, ending in rapidly fatal peritonitis; and if this accident does not occur, the dyspeptic symptoms become complicated by hæmorrhage from the stomach, sometimes so rapid that it distends the stomach and adjacent small intestine with a single gush, and causes fainting and almost immediate death; but more commonly occurring as a slow and intermittent drain of blood, giving rise to anæmia. If death from the above causes (inanition, perforation, or hæmorrhage) does not terminate the disease, the symptoms frequently subside in something like the inverse order in which they occurred, and recovery, often after many years' suffering, ensues. With regard to frequency of ulcer of the stomach, Dr. Brinton, who has carefully studied this disease, states that this lesion may be detected in (on an average) 5 per cent. of persons dying from all causes; that it occurs twice as frequently in females as in males, and that it is specially a disease of middle and advancing life—27 being the average age in females, and 42 in males. Nothing is known with certainty regarding the causes of this disease, except that advancing age, privation, mental anxiety, and intemperance so frequently coincide with it, that they may be regarded in some degree as producing it.

In relation to treatment, strict attention to diet is of the first importance. When the symptoms are urgent, the patient should maintain the recumbent position, and should be fed on lukewarm milk, thickened with biscuit-powder, given in doses of one, or at most, two table-spoonfuls every two hours. The pain is often relieved by the application of a mustard-poultice to the painful spot; and benefit is frequently derived from the internal administration of bismuth (in doses of ten grains), either given alone or combined with the compound kino powder (in five-grain doses). When there is hæmorrhage, small lumps of ice may be swallowed; and if all food is rejected by vomiting, beef-tea injections must be thrown into the lower bowel. Aperients are sometimes required, but they must be given with caution; and if castor-oil can be taken without increasing the pain or vomiting, it is the most harmless remedy of its class.

Cancer of the Stomach is a disease of much interest, from its being obscure in its symptoms and difficult of detection in its early stage, frequent in its occurrence, and always fatal in its termination. The typical course of this disease is graphically sketched by Dr. Brinton in the following paragraph: 'An elderly person perhaps hitherto free from dyspepsia, begins to suffer from a capricious, and soon a diminished appetite; which is by and by associated with occasional nausea, or even vomiting, and with a sense of uneasiness or distention of the stomach. His complexion, already pale and unwholesome, next acquires a muddy, yellowish, or faint greenish hue. His gastric symptoms now increase; often by a sudden and marked augmentation, which corresponds to what is, in other cases, their first appearance. Vomiting, if already present, becomes more frequent and urgent; local uneasiness deepens into pain; and both these symptoms are excited or increased by taking food.

'At a somewhat later period, hæmorrhage generally occurs, usually but scanty in amount, and therefore depending to a great extent on casual circumstances for its detection. About this time, a tumor often becomes perceptible near the middle of the epigastric region of the belly. As the local symptoms increase, the cachexia of the patient also augments; and is evidenced not only by the color already mentioned, but also by debility and emaciation; and at last by prostration, which ends in anasarca, delirium, and death.'—*Op. cit.*, p. 225. From the records of 600 cases, Dr. Brinton finds that most deaths from this disease occur between the ages of 50 and 60 years. The form of cancer which most frequently attacks the stomach is the scirrhus or hard cancer. Out of 180 cases, scirrhus occurred in 130 (or nearly three-fourths of the whole), medullary or encephaloid cancer in 32, colloid in 17, melanotic deposit in 3, and villous cancer in 1. In the treatment of this formidable disease, more good is done by careful attention to the diet than by any medicine. Good milk or strong beef-tea thickened with biscuit-powder, may be given in the same manner as recommended in ulcer; and milk mixed with a little old Jamaica rum will sometimes stay on the stomach when everything else is vomited. If there be pain, opiates must be given, and they may be prescribed either in the ordinary way, or as enemata, the latter having the advantage of not inducing constipation.

Hæmatemesis, or *Vomiting of Blood*, must be looked upon rather as a symptom than a disease. Thus, it may occur by the ulcerative destruction of the walls of a comparatively large blood-vessel, as in gastric ulcer and in cancer; but it generally is of the kind termed capillary. The latter kind of hæmorrhage happens under various circumstances, of which the following are the principal: 1. The bleeding may be idiopathic, or unaccompanied by any structural change. This variety is extremely rare. 2. It may take the place of some habitual hæmorrhage, or, in other words, be vicarious. Thus it frequently takes the place of the menstrual discharge. 3. It is often a consequence of disease or injury of the stomach; for example, it frequently occurs after the ingestion of strongly irritant poisons, or even an immoderate dose of alcohol into the stomach. 4. It may be a consequence of disease in adjacent viscera, occasioning an overloading of the veins of the stomach; thus it is frequently caused by enlargement of the spleen, and occurs in those states of the liver in which there is obstruction of the portal circulation; and under this category we must place the gastric hæmorrhage which not unfrequently occurs in the advanced periods of pregnancy, in consequence of the pressure exerted by the enlarged uterus on the venous circulation of the abdomen. 5. It may result from changes in the composition of the blood, such as occur in scurvy, purpura, and yellow fever. The treatment must be directed against the disease on which the hæmorrhage depends, rather than against the mere symptom; but from whatever cause it arises, if it is proceeding to a dangerous extent, the patient should be kept perfectly quiet in bed, and should swallow small pieces of ice.

Hot applications may also be applied to the extremities, with the view of directing the blood to those parts. The medicines most likely to be of service are acetate of lead, gallic acid, dilute sulphuric acid, and oil of turpentine; but they should only be given on medical authority.

Some of the other affections of the stomach are discussed in special articles. See CARDIALGIA, INDIGESTION, SARCINA, &c.

STOMA'PODA (Gr. mouth-footed), an order of malacostracous crustaceans, to which *Squillidæ*, Glass-crabs, &c. belong. All of them are marine. They are most abundant in tropical seas, but some are found in those of temperate parts of the world. They

have seven or eight pair of legs, mostly near the mouth. The gills are external, adhering to the appendages beneath the abdomen, which is elongated, and terminates in an extended tail-fin. The rings which bear the eyes and the antennæ are not confounded with the rest of the head, as in the *Decapoda*, but are more distinct. The carapace often leaves the latter rings of the thorax exposed. The heart is very different from that of the *Decapoda*, assuming the form of a long cylindrical vessel, which extends throughout the length of the abdomen.—The S. inhabit deep parts of the sea, many of them living at the bottom, whilst some, as Glass-crabs, are found floating at the surface.

STO'MATA (Gr. mouths) are minute openings in the epidermis of leaves and other green parts of plants exposed to the air, communicating with intercellular spaces. Their existence was first noticed by Grew, who described them in his *Anatomy of Plants* in 1682. They are generally formed by two semilunar cells, which are as lips to the orifice, and are filled with green matter; but sometimes the cells arranged around them are more numerous. They are generally of an elliptical form, but sometimes circular, and sometimes quadrangular. These differences are very characteristic of particular species, genera, or orders of plants. In a moist state of the atmosphere they are open; but when it becomes dry, they are closed, or nearly so. It appears that they are organs of transpiration, and that their opening and closing according to the moisture or dryness of the atmosphere regulates it in a manner suitable to the requirements of the plant. They do not occur in any part of the plant covered by the soil, nor in submerged leaves, nor on the lower side of floating leaves. Succulent plants have very few of them; so that these plants retain for a long time the moisture which they have imbibed, and are thus adapted for living in a dry atmosphere. S. are generally most abundant on the under side of leaves; but in leaves which grow vertically, they are often almost equally numerous on both sides. In general, they are irregularly placed; but in grasses and many other endogenous plants with parallel-veined leaves, they are in regular rows; and in some other plants they occur in little groups. The number in a square inch varies from 200 in the mistletoe, to almost 450,000 in the under side of the leaves of *Salanum sanctum*.—S. are not found in mosses, lichens, algæ, and fungi; but they exist in some of the *Hepaticæ*, as in *Marchantia*, in which their structure is more complex than in the higher plants; each of them consisting of a kind of shaft, composed of four or five rings placed one upon the other, every ring made up of four or five cells, and the lowest ring apparently regulating the aperture by the contraction or expansion of the cells which form it.

STONE, a market-town of Stafford, stands 7 miles north-north-west of the town of that name, on the left bank of the Trent. Shoemaking, tanning, malting, and brickmaking, are the chief branches of industry. Near the church are some remains of an Augustinian monastery. Pop. (1871) 3732; (1881) 5669.

STONE, a weight in use throughout the north-west and central countries of Europe, but varying much in different countries. It is chiefly employed on the continent for weighing wool, hemp, flax, and feathers, the flax-stone containing twice as many pounds as the one used for wool and feathers. In all the principal commercial states of Germany, the stone (of flax) is the $\frac{1}{4}$th of a cwt. (centner = 100 or 112 lbs.), i. e., 20 lbs., in Prussia and the Zollverein, Hamburg, Lübeck, and Bremen; 22 lbs. in Austria, &c.; in Britain, it is the $\frac{1}{8}$th of a cwt., or 14 lbs.; while in Sweden it is equivalent to 32 lbs. In Great Britain, though the stone of 14 lbs. is the only legal imperial weight of the kind, stones of other values are in regular use, as a stone of 24 lbs. for wool, and one of 8 lbs. for butcher-meat.

STONE. See CALCULUS and LITHOTOMY.

STONE is used for a great variety of purposes—for building, paving, millstones, grindstones, honestones, ornamental purposes, &c. Besides what is said under special headings (see BUILDING STONE, QUARRY, MILL, GRINDSTONES, HONES, MARBLE, GRANITE, SLATE, &c.), the following general remarks may be added here. The desirable properties in a building-stone are, that it should be compact, insoluble in water, not easily altered by the atmosphere, and not liable to take on a vegetable coating. These qualities depend upon its chemical composition and on its mechanical structure.

Building stones may be divided into three classes—siliceous, calcareous, and composite. Siliceous stones (including granite, porphyry, gneiss, greenstone, basalt, sandstone, slate, serpentine, &c., and containing from 45 to 99 per cent. of silica), are, as a general rule, the most durable for building. Their durability is affected by certain of their ingredients, as by the felspar in granite, and salts of iron in sandstone. Calcareous stones (simple limestone, travertin, marble, &c.) are slightly soluble in pure water, and more so in carbonic acid water; they are liable to splinter by water freezing in their pores, are acted on by acid gases (e. g., the sulphurous acid gas produced by the combustion of most kinds of coal), and are somewhat liable to be stained by minute plants. Still, some of them are lasting enough in a country atmosphere. The failure of the magnesian limestone selected for the British Houses of Parliament is a good instance of a stone lasting for centuries in a country church, and yet quite unable to withstand the wasting action of the atmosphere of a great city. Composite stones, in which neither the silica nor the lime greatly predominates, are unimportant.

The most exhaustive account of the building stones of the British Islands is given in the parliamentary Blue Book embodying the Report of the Commissioners appointed to select a stone for the Houses of Parliament, published in 1839. Much scientific information regarding all kinds of stone will be found in the catalogue of the Rock Specimens of the Museum of Practical Geology, London.

STONE, ARTIFICIAL. Artificial stone, properly speaking, would include burned clay wares used for building purposes, as bricks, Terra Cotta (q. v.), &c., as well as the various cements. We shall confine ourselves here to a description of the siliceous artificial stone produced by the cementing properties of soluble alkaline silicates on sand, which has excited a great deal of attention within the last thirty years. So far back as 1825, Professor J. N. von Fuchs of Munich published a paper on various applications of these silicates, and so laid the foundation of a new industry. To M. Kuhlmann of Lille, however, is mainly due the merit of working out the practical application of the soluble silicate of potash or soda to the manufacture of hydraulic lime, cement, and especially to artificial stones. Mr. Frederick Ransome of Ipswich has also done great service by his successful exertions in producing an artificial stone from the same substances. The process, as at first practised by Mr. Ransome, consisted in mixing the gelatinous silicate of soda with sand and a little powdered glass and clay, in the proportions of sand, 10 parts; glass, 1 part; clay, 1 part; and silicate of soda, 1 part. These ingredients were thoroughly incorporated in a pug-mill, and brought to the consistency of putty. The plastic nature of the substance at this stage allows it to be moulded with ease into an endless variety of forms, even of an elaborately ornamental kind. After leaving the moulds, the objects are dried in close ovens, and then removed to kilns, where they are fired at a gradually increasing temperature, which finally reaches a red heat. In the kiln, the goods are bedded up in dry sand, to prevent any of the twisting or loss of shape which so commonly disfigures large objects in baked clay. When the firing is completed, the material is in the state of a semi-vitrified mass, with the appearance, properties, and composition of a fine sandstone.

A later patent of Mr. Ransome's consists in producing a hard and durable material altogether without baking, by effecting a double decomposition with the silicate of soda and the chloride of calcium. Such materials as sand, chalk, or other minerals are intimately mixed with a proper quantity of a solution of silicate of soda, this being secured, as before, by the operations of a pug-mill. In this plastic condition, they are moulded into any required form, after which they are saturated with a solution of chloride of calcium. The silica combining with the calcium forms at once an insoluble silicate of lime, which cements into a firm mass all the particles of sand, lime, &c., used in the composition. The chlorine, on the other hand, combines with the soda to form common salt (chloride of sodium), which can be readily removed by washing.

In order to avoid the difficulty experienced in removing all traces of chloride of calcium from artificial stone made by this last process, Mr. Ransome in 1872 succeeded in making a very compact stone by mixing lime and a natural soluble silica found in a rock forming a stratum of the lower chalk in Surrey with sand and silicate of soda. In point of strength this material excels Portland stone, not breaking so readily by a given transverse strain.

The objects into which artificial stone is manufactured are very miscellaneous; whatever, in fact, is made of real stone can also be formed in the artificial. Among the more prominent applications of it, we may notice grindstones, millstones, tombstones, monuments, chimney-pieces, balustrades, fountains, vases, and statuary.

STONE CHAT (*Saxicola rubicola*; see CHAT), one of the most common of the British *Sylviadæ*, a pretty little bird, rather smaller than the redbreast, black on the upper parts and throat in summer; the breast of a dark reddish color; some white on the sides of the neck, the wings, and the tail. It makes its nest on the ground, or on a low branch. Some stone-chats spend the winter in Britain, but the greater number migrate to more southern regions.

STONECROP. See SEDUM.

STONE-CUTTING AND DRESSING MACHINES. Stone is a substance which in none of its varieties is easily operated on

by machinery, owing chiefly to its brittleness, its unequal hardness, and the natural cracks which so frequently impair its solidity. Accordingly, though many ingenious machines have been invented for working stone, it is as yet only in some of the plainer kinds of work that they can be said to have entirely superseded hand operations.

Some stones and slates are soft enough to be cut with ordinary toothed saws much in the same way as wood is cut. More generally, however, the sand-saw is employed, which we shall presently describe in noticing marble-cutting. For the cutting of common kinds of stone, which are not to receive a fine polish, a machine, which promises to be very efficient, has been recently patented by Mr. George Hunter of Maentwrog, Caernarvon, and is now in operation at various large quarries, both of stone and slate. The cutting portion consists (fig. 1) of a circular disc, A, A (two of

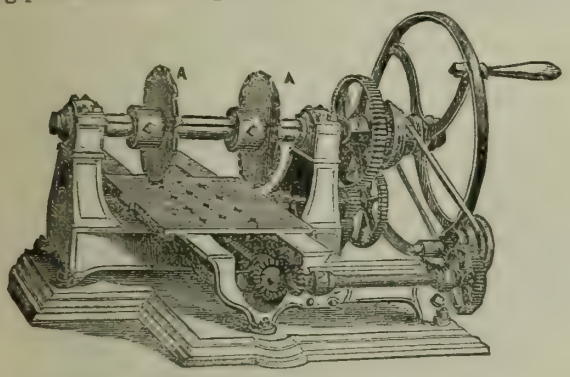

Fig. 1.

these are shown in the figure, but the number varies), round the circumference of which a number of pointed steel tools are fixed into sockets, thus giving it the appearance of a large toothed saw. This machine will cut sandstone at the rate of 5 to 6 inches, slate at 3 inches, and soft limestone at 3 inches per minute, supposing these to be in blocks each 2 feet thick.

So far as the sawing or slicing of stones is concerned, the tendency of late years is to rely on the use of the diamond—the dull black variety which is of no use as a gem. Some American stone-cutting machines have saws with teeth set with these diamonds, and are said to cut ordinary sandstone at the rate of 75 square feet per second for each saw. Machines for dressing the face of stones by means of a series of chisels in imitation of the hand-work of the mason have recently been tried and have given fair results.

It is considerably more than a century since machinery for sawing and polishing marble was first established at Ashford, near Bakewell, in Derbyshire, that county being still the seat of the principal marble manufacture of England. Marble is cut into slabs by means of a series of thin plates of soft iron used like saws, but having no teeth. The saw-blades are fixed into a rectangular frame, to which a reciprocating horizontal motion is given. The block of marble to be cut rests on a carriage below the frame, and a small rill of mixed sand and water is constantly falling into the saw-cuts.

After the marble has been sawn into slabs, it is cut up into narrow pieces, when so required, by means of small circular saws with smooth edges, sand and water being employed as above.

The sawn slabs are next submitted to the grinding process. This, for pieces of moderate size, is usually done upon a large circular cast-iron plate, called a *sanding-bed* or *grinding-bed*, mounted upon an upright spindle, and supplied with sand and water. The workman places the piece of marble with its face downwards upon the grinding-bed, and exerts the proper amount of pressure. The marble is held in its place by means of guide-rods stretched across the plate. Slabs too large to be manipulated in this way are ground with plates of iron operating upon their surface.

The marble, when properly ground, is polished on a polishing bed or table, with an arrangement for securely fixing it while the rubbing is being proceeded with. The polishing rubbers are sometimes blocks of wood faced with felt, and sometimes bunches of hemp compressed between two side-plates. They are attached to a swing-frame with a pendulum-like motion, which draws them backwards and forwards over the surface of the marble. Flour emery is used to charge the rubbers in the first instance, and putty-powder (oxide of tin) for the finishing polish. Instead of emery, sometimes the fine-grained stone known as Water of Ayr stone is used to prepare the marble for the putty-powder.

Cylindrical objects, such as columns or vases, are first formed roughly into shape with a hammer and chisel, and then turned, with a pointed steel tool, upon a lathe, to which a slow motion is given. When thus brought to an accurate form, a rapid motion is given to the lathe, and the tool-marks ground away by the use of coarse, and then fine, and still finer sandstones—the polishing being completed with emery and putty powder while the object is still upon the lathe.

Machinery is also applied to the production of flat objects with curved and moulded outlines. Fig. 2 represents the essential parts of a machine for this purpose. It operates by the use of a rotatory cutter, which is guided in its action by a template formed accurately to the intended shape of the article. The cutter, *a*, is of steel or stone, and is attached to the lower end of a spindle driven by bevelled wheels. There is a flange at *b*, which allows the cutter to penetrate the marble till it reaches the template, *c*, and no further. In the process of cutting, the marble, which we will suppose is to receive the shape shown at S (fig. 3), but only

Fig. 2.

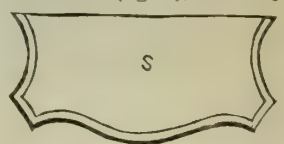

Fig. 3.

seen on edge at *d*, in fig. 2, is constantly drawn up against the cutting-tool by two weights, the one pulling the table, *h*, in one direction, the other the carriage on which *h* rests, in a direction at right angles to the former, thus compelling the cutter to follow the outline of the template. The shape of the cutting-tool is, of course, exactly the reverse of the moulding to be formed.

In the cutting and polishing of granite, the machinery and processes are so nearly the same as those employed for marble, that it is unnecessary to describe them separately. Suffice it to say, that all objects to which the sawing apparatus cannot be applied, require to be worked to shape with great care by means of steel chisels and iron mallets, which only remove small portions at a time. Owing to the great hardness of the material, any defect in the chiselling greatly increases the labor of polishing. So slow, indeed, are the operations with granite, that a saw-blade will not cut through an inch in depth during a whole day, and a good-sized sawn slab will take a week to polish.

STONE-FLY (*Perla*), a genus of Neuropterous insects, of the tribe or family *Planipennes*. The hind wings are broader than the fore-wings, and folded at the inner edge. The body is elongate, narrow, and flattened; the wings close horizontally on the body; the abdomen is generally terminated by two bristles (*setæ*). The larvæ are aquatic, and much resemble the perfect insect, except in the want of wings. A number of species are common in Britain, and are well known to anglers as an attractive lure for fishes.

STONE-FRUITS, in Popular Language, are those fruits which are botanically designated *drupes*, and in which the rind is fleshy, and the putamen bony. Many of the finest dessert fruits are of this description. Those best known in temperate climates generally belong to the natural order *Rosaceæ*, sub-order *Amygdaleæ*, the order *Drupaceæ* of Lindley, as the peach and nectarine, plum, cherry, apricot, &c. In tropical countries, many stone-fruits occur, belonging to *Chrysobalanaceæ* and other natural orders.

STONEHA'VEN, a seaport town of Scotland, capital of the county of Kincardine, and a station on the railway from Dundee to Aberdeen, is situated on a rocky bay at the mouth of Carron Water. It is divided into an Old and New Town, on different sides of the river, and connected by a bridge. The harbor can admit only small vessels. S. has very considerable haddock and herring fisheries, and some slight manufactures. Pop. (1881) 3957. Two miles south, on a projecting rock, stands the famous castle of Dunnottar, once the residence of the Earls Marischal.

STO'NEHENGE (Sax. *Stanhengist*, hanging or uplifted stones), a very remarkable structure, composed of large artificially raised monoliths, situated on Salisbury Plain, two miles from the town of Amesbury, in Wiltshire. Its neighborhood abounds in sepulchral tumuli, in many of which ancient British remains have been found. The fabric of S., which was comparatively entire in the early part of the present century, has been so much defaced in recent times as to be at first view little more than a confused pile of moss-grown stones; but a minute inspection will still enable one to trace its original form. When entire, it consisted of two concentric circles of upright stones, enclosing two ellipses, the whole surrounded by a double mound and ditch circular in form. Outside the boundary was a single upright stone, and the approach was by an avenue from the north-east, bounded on each side by a mound or ditch. The outer circle consisted of 30 blocks of sandstone, fixed upright at intervals of 3½ feet, and connected at the top by a continuous series of imposts, 16 feet from the ground. The blocks were all squared and rough-hewn, and the horizontal imposts dove-tailed to each

other, and fitted by mortise-holes in their under sides to knobs in the uprights.

About 9 feet within this peristyle was the inner circle, composed of 30 unhewn granite pillars, from 5 to 6 feet in height. The grandest part of S. was the ellipse inside the circle, formed of 10 or 12 blocks of sandstone, from 16 to 22 feet in height, arranged in pairs, each pair separate, and furnished with an impost, so as

Stonehenge.

to form 5 or 6 trilithons. Within these trilithons was the inner ellipse, composed of 19 uprights of granite similar in size to those of the inner circle; and in the cell thus formed was the so-called altar, a large slab of blue marble.

There has been much speculation regarding the origin and purpose of S., which are still involved in much obscurity. A curious legend, first found in the *British Chronicle* of the 10th c., and repeated by Geoffrey of Monmouth and Giraldus Cambrensis, ascribes it to Emrys or Ambrosius, the last British king, who, in the 5th c., aided by the incantations of the magician Merlin, is said to have erected it in memory of 460 Britons, who were murdered by Hengist the Saxon. In modern times, the most prevalent opinion has been that, in common with other similar structures elsewhere, it was a temple for Druidical worship; but this belief has been somewhat shaken by the discovery of the sepulchral character of many other monuments, which had been also presumed to be Druidical. The circular form has suggested the idea of a connection with the worship of the sun; and S. may possibly have been used for the religious rites of various successive races and creeds; and also as a court of justice or battle-ring for judicial combats. The outer circle is evidently of a much later date than the rest, and seems to belong to a period when iron tools were in use. See STANDING STONES.

STO'NEHOUSE, EAST, a parish of Devonshire, included within the limits of the parliamentary borough of Devonport (q. v.), and forming in effect a portion of Plymouth (q. v.). Among other government establishments, it contains the Royal William Victualling Yard, naval hospital, and marine barracks capable of accommodating 1000 men. Pop. of parish, (1881) 15,041.

STONE PERIOD. See BRONZE, AGE OF.

STONE-POCK, an old name for a variety of modified smallpox, in which the vesicles dried up into hard tubercles instead of proceeding onwards to maturation.

STONE, PRESERVATION OF. The mechanical preservation of stone can be effected to a great extent by coating the surface with boiled linseed oil, or with oil-paint; but these methods are not much in favor, as they destroy the crystalline appearance which constitutes the beauty of most natural stones. As promising a better result, many experiments have been tried, especially of late, with certain chemical solutions that are not likely to mar the inherent beauty of a stone. The substances which have been most used are those soluble silicates which we have referred to under ARTIFICIAL STONE. The earlier process of Kuhlmann consisted in coating the surface with a soluble silicate of soda or potash, which is also known by the names of soluble glass, water-glass, and flint liquor. This was applied with a brush, and silification was produced by the silica of the solution entering into combination with the lime of the stone; but this took a considerable time, so that, on an exposed front, it was liable to be washed out before the proper hardening took place. The later process of Ransome consists in cleaning the surface of the stone from extraneous matter, and then applying alternate solutions of the above alkaline silicate and chloride of calcium, which forms an insoluble silicate of lime in the pores of the stone. This plan has been tried with a portion of the new Houses of Parliament many years ago, and is now extensively used in London, Edinburgh, Glasgow, and elsewhere. Ransome's process is indeed practically the only one in use. But the preservation of the Houses of Parliament has been the subject of inquiry since this invention was applied to them; and the committee which sat did not succeed in discovering any preserving agent which they felt justified in proposing. The chemists engaged in this inquiry selected, from a vast number of proposals then made, the following processes, as claiming a careful investigation: 1. Application of silicates of the alkalies, in various states of concentration; 2. Application of silicates, in conjunction with various saline compounds, intended to produce double decomposition; 3. Application of hydrofluoric or hydrosilicic acid, or their saline compounds; 4. Application of phosphoric acid and acid phosphates; 5. Applications of solutions of the alkaline earths, or their bicarbonates, in water.

STONE-WARE. See POTTERY.

STO'NINGTON, a town and port of entry of Connecticut, U. S., at the eastern extremity of Long Island Sound, 63 miles east of New Haven, and at the junction of one of the railway and steamer routes between New York and Boston. It has a fine harbor, with 17,000 tons of shipping, engaged in coasting trade and fisheries, and numerous manufactories. S. was settled in 1649. Pop. (1880) 7355.

STO'NY POINT, a small rocky promontory on the right bank of the Hudson River, at the entrance of the Highlands, 42 miles north of the city of New York. This and the opposite Verplancks Point were fortified in the war of the Revolution, and were the scene of several contests.

STONYHURST COLLEGE, 7 miles north-east of Blackburn, Lancashire, a Roman Catholic institution, founded in 1794, was affiliated to London University in 1863, and prepares candidates for matriculation at the universities, and for the civil and military services. It has a staff of about 20 professors and masters.

STOOL OF REPENTANCE, the name ordinarily given in Scotland to a low stool conspicuously placed in front of the pulpit in churches, on which persons who had become subject to ecclesiastical discipline for immoral conduct were required to sit during public worship, in profession of their penitence, or on which they stood at the close of the service to be 'rebuked' by the minister. It was also familiarly called the *cutty* stool, a term applied to small stools of similar form, common in houses, but which came to be often employed in conversation and in humorous verses with special reference to that which stood in the church. The Stool of Repentance, although used in some places within the present century, has now fallen into complete disuse; whilst the practice of formal public rebuke has also generally been laid aside.

STOP, or REGISTER, a name given to the different ranges of pipes in an organ. Each stop consists of a series of pipes, of the same quality of tone, extending throughout the whole or a large part of the compass of the instrument, and furnished by a draw-stop or knob, on drawing which out, the air is admitted to the particular stop, so that the keys will play on pipes of that character. Some of the stops do not give the note which corresponds in pitch with the key struck, but a note an octave or two octaves lower, or one of the harmonics higher in pitch. Compound or mixture stops consist of more than one row of pipes to each key, corresponding to the different harmonics of the ground tone. The stops of different organs vary much in number and kind; a very large number are to be found in many of the organs in Germany and Italy. See ORGAN.

STO'PPAGE IN TRA'NSITU is a valuable right or privilege of a vendor of goods to resume possession, after he has parted with them under a contract of sale, and before the goods have reached the vendee. It occurs when goods are consigned entirely or partly on credit from one person to another, and the consignee becomes bankrupt before the goods arrive. In this event, the consigner has a right to direct the captain of the ship or other carrier to deliver the goods to himself or his agent instead of the consignee, who has thus become unable to pay for them. This right was first allowed as equitable by the Court of Chancery, and the courts of common law followed the example. There are certain circumstances, however, in which the right to stop *in transitú* may be defeated, as where the consignee of the goods indorses the bill of lading to a *bonâ fide* indorsee. When the vendee has appointed the carrier who is to receive the goods, their delivery to the carrier is treated for many purposes as delivery to the vendee himself; yet it is not too late for the vendor to stop the goods so long as they have not come into the actual possession of the vendee. The right to stop *in transitú* is not allowed to a vendor unless in case of the bankruptcy of the vendee or his stoppage of payment.—The same rule extends to Scotland.

STOPPAGES, MILITARY AND NAVAL, are certain deductions made from the pay of officers and men, in consideration of supplies made to them, or in aid of certain institutions. These stoppages were formerly more numerous than now. Thus, every officer and man had to pay towards Chelsea and Greenwich hospitals, and a soldier had to pay for his kit by a stoppage from the bounty. These stoppages have been remitted. Those now remaining are, under ordinary circumstances, limited in the navy to payment for slops (i. e., clothing) issued to men, or for wilful damage: in the army, for forage, 8½*d.* each ration by cavalry officers, and 6*d.* for artillery officers (though their horses eat the same); for messing on board ship; for diet in hospital, if sick

through the man's own fault; for cost while in prison; for damages to barracks; and as a fine for drunkenness.

STO'RAX, a fragrant resinous substance, the *styrax* of the ancients, obtained from the Storax-tree (*Styrax officinalis*), a native of the countries around the Mediterranean Sea, and belonging to the natural order of *Styracaceæ*, an order of exogenous plants, containing more than 100 known species. The species of this order are found in the tropical and subtropical parts of Asia, extending also into Europe and Africa, and the warm parts of America. *Styrax officinalis*, which produces S., is a tree of 15—20 feet high, a native of the Levant. S. is obtained by wounding the bark, when it exudes and hardens in the air. It appears in the form of reddish-yellow tears about the size of a pea, opaque, soft, and adhesive; or in dry brittle masses, wrapped in the leaves of a kind of reed, when it is called *S. calamita*. S. has a fragrant odor and an aromatic taste, and is stimulating and expectorant it was formerly much more in use in medicine than now. Benzoin (q. v.) is the produce of a species of *Styrax*. The *Liquid S.* of the shops is doubtfully regarded either as produced by *Styrax officinale*, or by a species of *Liquidambar* (q. v.). It seems probable that there are two kinds.

STORK (*Ciconia*), a genus of birds of the same family (*Ardeidæ*) with herons and bitterns; large birds; with long legs, four-toed, the three front toes webbed to the first joint; the tail short; the wings large; the bill longer than the head, straight, strong, pointed, and without any groove, the nostrils pierced longitudinally in the horny substance; the eyes surrounded by naked skin. In some storks the whole face and throat are destitute of feathers. The species are not numerous (about a dozen), but they are of very wide geographic distribution. The COMMON S., or WHITE S. (*C. alba*), is a native of the greater part of the Old World, a migratory bird, its range extending even to the northern parts of Scandinavia. It is common in most parts of Europe, but is especially familiar in Holland and North Germany. The storks arrive annually in February and March, and in autumn return to Africa in large flocks, flying mostly by night. It is about three feet and a half in length. The head, neck, and whole body are pure white; the wings partly black; the bill and legs red. The neck is long, and generally carried in an arched form; the feathers of the breast are long and pendulous, and the bird often has its bill half hidden among them. The flight is very powerful and high in the air; the gait slow and measured. In flight the head is thrown back, and the legs extended. The S. sleeps standing on one leg, with the neck folded, and the head turned backward on the shoulder. It frequents marshy places, feeding on eels and other fishes, frogs, lizards, snakes, slugs, young birds, small mammals, and insects. It makes a rude nest of sticks, reeds, &c., on the tops of tall trees, or of ruins, spires, or houses. There are four or five eggs; white

Storks and nests.

tinged with buff; and the old nest is re-occupied next year. In many parts of Europe, especially in Holland, it is a very common practice to place boxes for storks, and it is considered a fortunate thing for a household that the box on the roof is occupied.

Storks are protected by law in some countries, on account of their good services not only in destroying reptiles and other troublesome animals, but in the removal of offal from the streets of towns, in which they stalk about with perfect confidence, even in the midst of throngs of people. They have been celebrated from ancient times for the affection which they display towards their young; and have also had the reputation—not so well founded—of showing great regard to their aged parents. Before they take their departure from their summer haunts, they congregate in large flocks, which make a great noise by the clattering of their mandibles, and are popularly regarded as holding consultation. The S. has no voice. It is a very rare bird in Britain, and was so even when the fens of England were undrained. The flesh of the S. is rank, and not fit for food.—Another species, the BLACK S. (*C. nigra*), rather smaller, the plumage of the upper parts glossy black, the under parts white, is also common in many parts of Europe, Asia, and Africa.—The AMERICAN S. (*C. maguari*) is very similar to the Common Stork; it is common in South America, particularly Brazil.

STORMS are violent commotions of the atmosphere, occurring in all climates, particularly in the tropics, and differing from other atmospheric disturbances in the extent over which they spread themselves, their destructive power, and the sudden changes which take place in the direction of the wind. There is, perhaps, no question in science in which there has been so large an admixture of speculation with fact, as in the attempts made to reduce the phenomena attendant on storms under general laws; the reason being, that meteorological observatories were too few in number, and too wide apart, to enable any one to give the barometer pressure, the general course of the winds, and the rainfall, without drawing largely on conjecture. Now, however, owing to the growing popularity of meteorology, and the countenance happily given to it by most civilized nations, sufficient data may be obtained for a fuller and more satisfactory statement of the facts.

On the next page are two charts of Europe, showing, from actual observations made at upwards of 100 localities scattered over that continent, the barometric pressure, and direction and force of the wind, at 8 A.M. of the 1st and 2d of November 1863, during part of the course of two storms which passed over Europe at that time. The isobarometric lines, or lines showing where, at the above hours, the height of the barometer was the same, are given for every two-tenths in the difference of the pressure. Hence, where these lines approach near each other, or crowd together, the difference of pressure, or the atmospheric disturbance, was the greatest; and the least where they are most apart—a distinction of the utmost importance in determining where the storm may be expected to rage in greatest fury. The arrows show the direction of the wind, being represented flying with it. The force of the wind is shown (1) by plain arrows, ⟶, which represent light and moderate winds; (2) by arrows feathered on one side only, ⟶, which represent high winds; (3) by arrows feathered on both sides, ⟶, which represent strong gales, storms, or hurricanes.

The mean atmospheric pressure, at the level of the sea, may be stated to be 29·9 inches. When, therefore, the barometer falls below 29·9, the equilibrium of the atmosphere is more or less destroyed according to the amount of the fall, and it is within this *area of low barometer* that a storm may be expected to occur. Hence, while we trace these low pressures, as they advance over the earth's surface from day to day, we trace at the same time the progress of the storms.

Form and Extent of Storm Areas.—The circular isobarometric lines on the charts represent very accurately the general shape storms assume. The area of almost every storm is either circular or slightly elliptical, and when elliptical, the major axis of the ellipse seldom exceeds twice the length of the minor axis. Rarely in Europe, but in America less rarely, the form of storms is much more elongated. The outline is occasionally very irregular, but in all such cases the storm will be found to have parted into two or more distinct storms, which remain separate for some time and then re-unite. This circular form of storms, which an examination of some hundreds, especially in Europe, has shown to be their general characteristic, is a most important feature, whether as determining the practical rules for the guidance of sailors in storms, or for the forecasting of storms at particular seaports, in respect of the direction from which they may be expected to come, and the veerings of the winds during their continuance. The extent over which storms spread themselves is very variable, being seldom less than 600 miles in diameter, but often two or three times that amount, or even more. Almost the whole of Europe is sometimes overspread by a single storm at one time. The area of storms is by no means constant from day to day, but varies in size, sometimes expanding and sometimes contracting. And it is worthy of remark, that when a storm contracts its area, the central depression gives signs of filling up, and the storm of dying out. On the other hand, when it increases in extent, the central depression becomes deeper, the storm increases in violence, and

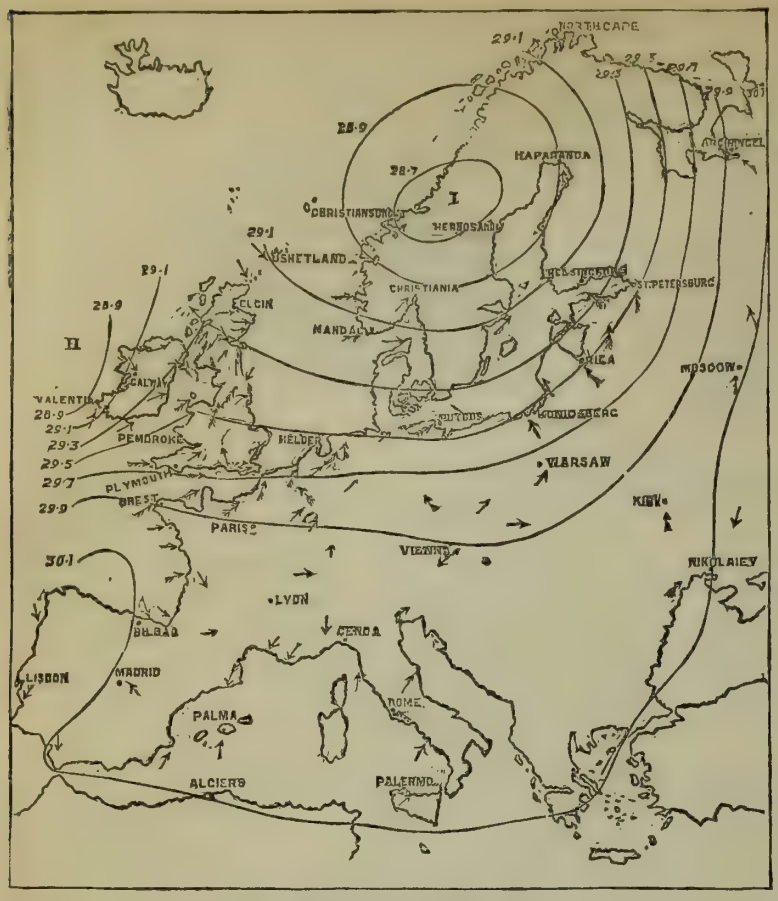

Fig. 1.—At 8 A.M., November 1, 1863.

occasionally is broken up into two, or even three depressions, which become separate storms, with the wind circling round each.

Direction in which Storms advance.—It may be premised that by the direction of a storm is meant, not the direction of the wind, but the path followed by the center of disturbance. The direction in which their progressive motion takes place differs in different parts of the world—being probably determined by the prevailing winds. See WINDS. Thus, about half the storms of middle and northern Europe travel from the south-west toward the north-east, and 19 out of every 20, at least, travel toward some point in the quadrant from the north-east to the south-east. Storms are thus rarely found traveling towards a westerly point; in some of the few instances which have been noted, this western course has been arrested at Norway, or Denmark, and they have retreated eastwards. Storms do not always proceed in the same uniform direction from day to day, and though the change which occurs in the direction of their progressive motion is generally small yet occasionally it is very great. Thus, of the many interesting features peculiar to the storm which passed over Europe in the beginning of December 1863, none were more remarkable than the sudden changes of its progressive motion. It was first observed on the west of Ireland, from which it advanced east to Liverpool, then turned south through Worcester and Oxford to Cherbourg in France; it thence retreated north through Oxford to Shields, from which it proceeded east to Copenhagen. By the time it arrived at Copenhagen its extent was only a fourth of what it had been the previous day, and the central depression half an inch less.

Twelve hours later, the atmospheric equilibrium was restored, the storm having died out on reaching the Baltic Sea. The storms of the Mediterranean follow a different course. Many of them proceed from the north to the south, influenced probably by the heated air rising from the Sahara; a considerable number proceed from the east, and pass to the westward over Greece and Italy to the Alps; while very few are observed to travel in an easterly direction. By far the greater number of the storms of North America take their rise in the vast plain which lies immediately to the east of the Rocky Mountains, and thence advance in an eastern direction over the United States; some of them, crossing the Atlantic, burst on the western shores of Europe. But the relation of the American to the European storms is not yet well established, nor will be till observation has collected more facts, and discussion has sifted their significance. If once the connection be fully established, the system of forecasting storms to European ports will become much more certain and complete than it is at present. The storms of the West Indies generally take their rise from near the region of calms, and tracing out a parabolic course, proceed first towards the north-west, and then turn to the north-east about 30° N. lat., many of them traversing the east coasts of North America as far as Nova Scotia. South of the equator they follow an opposite course. Thus, in the South Atlantic and Indian Ocean, they first proceed toward the south-west, and then gradually curve round to the south-east. The hurricanes of Hindustan usually pursue a parabolic path, first traversing the eastern coast towards Calcutta, and then turning to the north-west up the valley of the Ganges. The typhoons of the Chinese Seas resemble, in the course they take, the hurricanes of the West Indies. Observations are wanting from other parts of the world to determine the course of storms.

Probably the course tracked out by storms is determined by the general system of winds which prevail, modified by the unequal distribution of land and water on the surface of the globe. Facts seem at present to point to this general conclusion, viz., *Storms follow the course of the atmospheric current in which the condensation of the vapor into the rain which accompanies them takes place.*

Rate at which Storms travel.—If the position of the center of Storm I. on the 2d November be compared with its position on the 1st on the charts, it will be found to have traveled 420 miles in 24 hours, or at the rate of 17½ miles an hour. Similarly Storm II. will be found to have traveled in the same time 400 miles, or at the rate of 16⅔ miles an hour. This is not far from the average rate of the progressive movement of European storms. It is to be noted that storms travel with

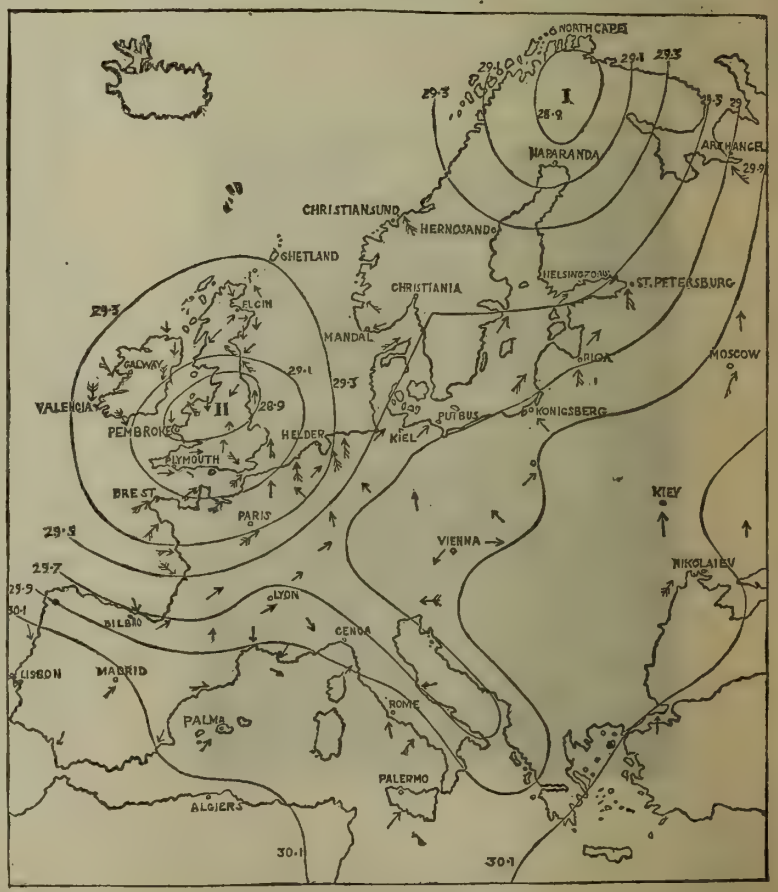

Fig. 2.—At 8 A.M., November. 2, 1863.

a less velocity over the ocean than over land. Within the tropics, the onward motion of storms sometimes rises to 40 miles an hour; whilst at other times the rate of motion is so slow as to be almost stationary.

Relations of Temperature, Rain, and Cloud to Storms.—The temperature increases a few degrees at places toward which and over which the front part of the storm is advancing, and falls at those places over which the front part of the storm has already passed. In other words, the temperature rises as the barometer falls, and falls as the barometer rises. When the barometer has been falling for some time, clouds begin to overspread the sky, and rain to fall at intervals; as the central depression approaches, the rain becomes more general, heavy, and continuous, and corresponding to the atmospheric depression at the place where it falls. After the center of the storm has passed, or when the barometer has begun to rise, the rain becomes less heavy, falling more in showers than continuously; the clouds break up, and fine weather ushered in with cold breezes ultimately prevails. It should be here remarked, that if the temperature begins to rise soon and markedly after the storm has passed, a second storm may be expected shortly.

Observations of the Wind.—First as to the direction of the wind. If the winds in Storm II. on the 2d November be attentively examined, they will be observed whirling round the area of low barometer in a circular manner, and in a direction contrary to the motion of the hands of a watch, with—and be this particularly noted—a constant tendency to turn inwards towards the center of lowest barometer. The wind in storms neither blows round the center of lowest pressure in circles, nor does it blow directly towards that center, but takes a direction nearly intermediate, approaching, however, nearer to the direction and course of the circular curves than of the radii to the center. The greater the force of the wind is at any place, it will be observed to approach the more nearly the direction here indicated. And where the direction of the wind differs to any material degree from this general law, it is light, and consequently more under local influences, which turn it from its course. Thus, the center of the storm being near Liverpool, the direction of the wind is south-west at Paris, south at Yarmouth, north-east at Silloth, north at Dublin, and north-west at Cork—instead of south at Paris, south-east at Yarmouth, north at Silloth, north-west at Dublin, and west at Cork, if it had blown directly to the area of lowest pressure; and west at Paris, south-west at Yarmouth, east at Silloth, north-east at Dublin, and north at Cork, if it had circulated in the direction of the isobarometric curves. Hence in this storm the winds circulate round the center of least pressure, or, to speak more accurately, the whole atmospheric system flows in upon the center in a spiral course. This rotatory peculiarity is common to all storms in the northern hemisphere that have yet been examined. In the southern hemisphere, a rotatory motion is also observed round the center of storms, but it takes place in a contrary direction, or in the direction of the motion of the hands of a watch, instead of contrary to that direction, as obtains north of the equator.

Professor Taylor has the merit of having first applied Dové's law of rotation to explain the direction of the rotation of storms round their center. This may be explained by referring to Storm II. on the 2d November. On that morning, the pressure over England being much less than in surrounding countries, if the earth had been at rest, air-currents would have flowed from all directions to England, to fill up the deficiency, in straight lines. The earth, however, is not at rest, but revolves from west to east; and as the velocity of rotation diminishes as the latitude increases, it is evident that the current which set out, say from Lyon to the north, would, on account of its greater initial velocity when it arrived at Paris, blow no longer directly to the north, but to a point a little to the east of north; in other words, it would no longer be a south, but a south-west wind. Again, since the current from the north of Scotland had a less velocity than those parts of the earth's surface on which it advanced, it lagged behind, and consequently, by the time it arrived at Silloth in the north of England, had changed from a north to a north-east wind. Similarly the north-west current changed to a north, the south-west to a west, &c. The west and east currents, since they continued in the same latitude, would have blown in the same direction, if they had not been disturbed by contiguous currents. Hence in a storm the whole system of winds rotates round the center. As a further confirmation of the truth of this theory, it is observed that when a high barometric pressure covers a limited space, the wind is always observed gently *whirling out of this area of high barometer*, but in exactly opposite directions in both hemispheres from those assumed when it blows round and in upon an area of low pressure. It follows in the northern hemisphere that as storms advance, the general veering of the wind at places lying north of the path of their center is from north-east by north to west; and at places south of their center, from north-east by east and south to north-west, and conversely in the southern hemisphere.

Next, as to the force of the wind: The rule is simple, and without exception—viz., the wind blows from a high to a low barometer, and with a force proportioned to the difference of the barometric pressures. Hence, where the isobarometric lines crowd together, the violence of the storm is most felt, and where they are far asunder, the winds are moderate and light. We thus see the importance of observations from a distance in forecasting the weather. To take an illustration: the importance of observations from Norway and Sweden to all seaports on the east coast of Britain cannot be overestimated. For if the pressure be high in Norway and low in the south of Great Britain, violent easterly gales will sweep down on Scotland, and unless foreseen and provided against, strew the coast with wrecks; whereas, if the pressures be nearly equal, little danger need be apprehended, even though the barometer be low in Britain. As the wind nears the center of the storm it gradually abates, till on reaching the center a lull or calm follows. Calms and light winds also prevail along the ridge of highest barometer, or the region where the pressure is greatest, and on receding from which the pressure diminishes on each side. It may not inaptly be compared to the watershed in physical geography, since from it the wind flows away towards the places where the pressure is less.

We have stated that the progressive motion of storms varies from 15 to 40 miles per hour, which measures the time taken in passing from one place to another, but it gives no indication of the violence of the storm. This is determined by the rotatory velocity of the wind round the center of the storm, which in Europe and America frequently amounts to 60 or 80 miles an hour continuously for some time. In intermittent gusts, a speed of 120 miles an hour has been several times observed in this country—a velocity which is perhaps sometimes surpassed by storms within the tropics.

Of the different theories hitherto proposed, we need only refer to the rotatory and the centripetal theories. The rotatory, or, as it is commonly called, the cyclonic theory, was first proposed by Piddington, and has since been elaborated by Redfield, Reid, Dové, and others. By this theory storms are considered as revolving round an axis either upright or inclined to the horizon, while at the same time the body of the storm has a progressive motion over the surface of the globe; the barometric depression, as caused by the centrifugal force, driving the air from the center to the circumference of the storm. Dové, certainly the ablest advocate of this theory, holds that cyclones are formed when two atmospheric currents, the equatorial and polar, flow side by side, they being, as it were, the eddies formed at the line of junction. To this theory several objections may be urged. Observations from the numerous observatories recently established in Europe and America, in no case exhibit a true cyclonic movement of the winds round the center of the storm; that is, they do not rotate in circles returning on themselves, even when the barometric depression is deepening and the storm expanding, but invariably exhibit, along with the rotatory motion, a constant tendency to blow in upon the center of the lowest pressure. Hence it is clear that the barometric depression is not caused by the centrifugal force of the storm. The same may be shown from theory; for though the wind were to blow round a circle 400 miles in diameter, at the rate of 70 miles an hour, the centrifugal force would depress the barometer at the center only $\frac{1}{200}$th of an inch; whereas half an inch, or even a whole inch of depression often occurs. Again, if cyclones arose from the flowing of the polar and equatorial currents side by side, the rotatory motion would not always be in one direction, but would be determined by the relative position and strength of the two currents. The whole facts of the rotation of the wind are explained when it is considered as caused by air currents flowing towards a low barometer along the globular surface of the earth rotating eastwards.

The rotatory character of storms has been denied by Espy, who maintains that the wind blows from every quarter towards the center of the storm, and that the central depression is caused by the development of heat, which occurs whenever the vapor of the atmosphere is condensed into cloud or rain; the heat thus developed rarefying the surrounding air, and causing an upward current. The most valuable part of this theory lies in directing the attention of meteorologists to the heat of condensation, which must play an important part in the movements of the atmosphere. It is, however, insufficient, since it leaves some important points unexplained. Thus, more heat being set free when vapor is converted into snow than rain, a greater depression ought to follow a fall of snow than of rain, which is not found to be the case; it also leaves unexplained the appearance of high pressures, sometimes suddenly appearing on the scene, and seeming to divert the storm from its course, or drive it before them. But the weak point of this theory is the centripetal direction of the winds. Espy worked from imperfect data, and never being able to lay down the isobar lines, he could only guess at the true center of the storm. Further, he was misled by a peculiarity of American storms; as these are generally in the

form of elongated ellipses moving *eastward*, many of the winds blow directly to the center, or nearly so.

It will be seen that much yet requires to be done before a complete and satisfactory theory of storms can be propounded. The most important desideratum is a large addition to existing meteorological observatories over the globe, by which, the weather being as it were photographed from day to day, storms with their attendant phenomena may be traced from the beginning to the end of their career; and then, the whole facts being known, the explanation or theory will doubtless soon follow.

STO'RNOWAY. See LEWIS-WITH-HARRIS.

STO'RTHING (from *stor*, great, and *thing*, court), the Legislative Assembly of Norway (q. v.). Its members are elected by certain deputies, who, in their turn, are chosen by a constituency comprising every native Norwegian of 25 years of age, who is a burgess of any town, or possesses property in land to the value of £33, the qualification for being elected, if 30 years of age, being the same. When the storthing is in session, every member is paid an allowance equivalent to about 13*s*. 4*d*. per day. When elected, the storthing meets of its own authority, without any writ from the king, and divides itself into two chambers, the *Lagthing* and the *Odelsthing*, the former composed of one-fourth, the latter of the remaining three-fourths of the members. Since 1869, the sittings have been held annually.

STORY, JOSEPH, an American jurist and judge, was born at Marblehead, Massachusetts, September 18, 1779, was educated at Harvard College, and though admitted to the bar in 1801, gave his attention chiefly to general literature and poetry. Having published a volume in 1804, *The Power of Solitude*, and other poems, which met with no success, he bade farewell to the muses, and devoted himself to law and politics. Elected to the state legislature in 1805, he became a leader of the republican, or, as it was afterwards called, the democratic party, and defended the measures of Jefferson. In 1808, he was elected to congress, where he gave a moderate support to the war measures of Mr. Madison, who, however, in 1811, appointed him associate justice of the Supreme Court of the United States, a place he filled with great credit for 34 years.

In 1820, as a member of the Massachusetts constitutional convention, he advocated a property basis for the senate. In 1829, he became law professor at Harvard. His later politics were of the Federalist school of Washington and Hamilton, and these tincture his *Commentary on the Constitution of the United States*. His *Conflict of Laws*, and other legal treatises, have passed through many editions. His legal writings and decisions are among those oftenest quoted in the higher courts of law. He died September 10, 1845.—In 1854 appeared S.'s *Miscellaneous Writings*; and in 1851 a life of him by his son, WILLIAM WETMORE STORY (born 1819), also educated as a lawyer, but better known as a sculptor and poet. *Roba di Roma* (1862) is the most successful prose work of the latter; the *Tragedy of Nero* (1875) his most notable poem.

STOTHARD, THOMAS, R.A., an eminent designer and painter, was the son of a London publican, who kept the *Black Horse* in Long Acre, and was born there in 1755. He received a respectable education in different boarding-schools, and on his father's death, having shown a predilection for the use of the pencil, was bound apprentice to a pattern-drawer in the city, but was released from his engagement before the term of expiry, and betook himself to more artistic work. His first notable effort was a series of designs for the *Town and Country Magazine*, which was followed by his imaginative composition for Bell's *British Poets*, and the *Novelist's Magazine*. The popularity of these was so great, that for many years his services were constantly in request by the leading publishers in London. His earliest pictures exhibited at the Royal Academy were 'The Holy Family,' and 'Ajax defending the Body of Patroclus.' In 1791 he was chosen an associate, in 1794 a member, and in 1813 librarian of the academy. He died 27th April 1834.

S. was really an admirable and facile illustrator. Not less than 3000 of his designs are known; but his paintings, although gracefully enough 'composed' and finely colored, are destitute of the originality that comes from a study of nature, and painfully resemble enlarged 'illustrations' for books. Perhaps the best known and the most agreeable of the set is his 'Canterbury Pilgrims,' engraved in 1817; others are the 'Flitch of Bacon,' the Fête Champêtre,' and the paintings executed for the staircase at Burleigh, the seat of the Marquis of Exeter. See Mrs. Bray's *Life of Thomas Stothard, R.A., with numerous illustrations from his Works* (1851).—His son, CHARLES ALFRED STOTHARD (born 1786, died 1821), acquired a great reputation as an antiquarian draughtsman.

STOU'RBRIDGE, a market-town in the county of Worcester, and 20 miles north-north-east of the town of that name, on the left bank of the Stour. It contains iron-works and glass, earthenware, and fire-brick factories. 'Stourbridge clay,' upon which the action of fire has less effect than upon most varieties of clay, is an article of export. Glass-house pots, crucibles, &c., are made of it. Pop. (1871) 9376; (1881) 9756.

STOU'THRIEFF, in the law of Scotland, means robbery committed in a dwelling-house.

STOVE, a fireplace in which the fire is generally quite shut in. The term is also applied to a room or closet heated for the purpose of drying and other operations, and to hothouses, in which the artificial heat is constantly maintained at a high temperature. Stoves for domestic purposes will be noticed under the head of WARMING AND VENTILATION. Particular kinds of hothouse stoves are already noticed in the articles BARK-STOVE and DRY STOVE. Stoves are also used for *forcing* fruits, so as to procure them in winter or spring. In the management of stoves, the general rule is that the temperature must never be allowed to fall below 60° F. The free access of air is, of course, desirable, but the windows are not opened unless the temperature reaches 70° F., and care must be taken that cold blasts do not enter, which are often very injurious.

STOW, or STOKE (A.-S., *stoc*, a stockaded place), a component element of many names of places, as Bristow, or Bristol, Stockholm.

STOW, JOHN, one of the earliest and most diligent collectors of English antiquities, was born in London in the year 1525. He was brought up to his father's trade of a tailor in Cornhill, but ultimately abandoned it for antiquarian pursuits. Writing in 1575, he says: 'It is now ten years since I, seeing the confused order of our late English chronicles, and the ignorant handling of ancient affairs, leaving mine own peculiar gains, consecrated myself to the search of our famous antiquities.' A patriotic sacrifice, which ought to have insured to the devoted antiquary from his king and country an old age of ease and honor, but which only brought him to want and beggary! In his 79th year, S. obtained letters patent from James I. authorizing him to become a mendicant, or, as it is expressed in the state document, 'to collect amongst our loving subjects their voluntary contributions and kind gratuities.' He died April 5, 1605, and was buried in the parish church of St. Andrew Undershaft, in Aldgate Ward, where his monument of terra-cotta, erected at the expense of his widow, may still be seen. The principal works of S. are his *Summary of English Chronicles*, first published in 1561, and subsequently reprinted every two or three years, with a continuation to the date of each new publication; *Annals of England*, 1580, and reprinted in 1592, to which year the annals are brought down; and *A Survey of London*, the most important of his writings, published in 1598. Besides these original works, S. assisted in the continuation of Holinshed's Chronicle, Speght's edition of Chaucer, Leland's *Collectanea*, &c. He had collected or transcribed a vast number of MSS., and much valuable information which might otherwise have perished; and in the use of his stores he was liberal to others, while as an original historian he was faithful and impartial.

STOWE, HARRIET ELIZABETH BEECHER, American authoress, daughter of the Rev. Dr. Lyman Beecher, and wife of Rev. Professor Calvin Ellis Stowe, was born at Litchfield, Connecticut, June 15, 1812. At the age of 15, she was engaged with her elder sister, Catherine, as teacher in a girls' school in Hartford. She was married to Professor Stowe in 1836, and became a frequent contributor to periodicals, published some stories in a volume entitled *The May-flower*, and other spirited juvenile stories for the Sunday-school libraries. The ability of Mrs. S. as a delineator of character, and especially of New England character, was known to many; but her full power was scarcely suspected, until, in 1851, she commenced in *The National Era*, an anti-slavery paper at Washington, a serial tale, entitled *Uncle Tom's Cabin*. When completed in 1852, it was published at Boston, and its popularity was so immense, that it soon sold in four stereotype editions to the extent of 400,000 copies The English reprints are estimated to have circulated 500,000, and it was rapidly translated into all European and some Asiatic languages, and was extensively dramatized and illustrated. In 1853, she published a *Key to Uncle Tom's Cabin*, and made a visit to Europe, where she was received with distinguished consideration. The events and impressions of this triumphant tour are recorded in her *Sunny Memories of Foreign Lands* (2 vols. Bost. 1854). In 1856, she published *Dred, a Tale of the Dismal Swamp*, another anti-slavery story, which had a wide circulation. This was followed in 1859 by *The Minister's Wooing*, a story of New England life in the 18th c.; &c. In 1869, Mrs. S. contributed to *Macmillan's Magazine* an article entitled *The True Story of Lady Byron's Life*, some statements in which, reflecting on the character of Lord Byron, gave rise to much stormy criticism, and occasioned her writing (1870) *Lady Byron Vindicated*, in which she replied to her critics. Mrs. S. was in 1868–70 joint-editor of *Hearth and Home*, and contributes to the *Independent* and other journals. Among her more recent works are *Little Foxes* (1865);

The Chimney Corner (1868); *Men of Our Times* (1868); *Pink and White Tyranny* (1871); *My Wife and I* (1872); *Poganuc People* (1878); *Queer Little People* (1881).

STOWELL, WILLIAM SCOTT, LORD, the eldest brother of Lord Eldon (q. v.), was born at Heworth, Durham, October 17, 1745. He was educated at Newcastle; went to Oxford in 1761, and became a college tutor. In 1779, he took the degree of D.C.L., removed to London, was called to the bar (1780), and admitted to the Faculty of Advocates at Doctors' Commons. Dr. Johnson introduced him to the Literary Club, and he became well known in the most intellectual society of London. As an advocate, he at once obtained a large practice, and his promotion was rapid. In 1788, he was appointed judge in the Consistory Court, knighted, and nominated a privy councillor. In 1798, he became judge of the Court of Admiralty, the highest dignity to which he could attain in his own branch of the profession. Both as an ecclesiastical and admiralty judge he won high distinction. He wrote no systematic treatise or text-book, but his judgments were admirably reported, and supply the best evidence of his extensive legal learning, his sagacity, and his great literary ability. He is the highest English authority on ecclesiastical law and the law of nations, and his judgments—those, especially, relating to the rights of belligerents and neutrals—have been described as the most valuable contribution made by an English judge to general jurisprudence since the time of Lord Mansfield. As a politician, Sir William Scott was not remarkable. He represented Oxford in the House of Commons for 20 years, but he took no part in the business of parliament, although, like his brother, he was a zealous supporter of the Conservative party and the established church. At the coronation of George IV. he was raised to the peerage under the title of Baron Stowell of Stowell Park. In 1828, he retired from the bench, and in 1836 he died. Lord S. was twice married, but only one child, Lady Sidmouth, survived him.

STOW'MARKET, a small market-town of Suffolk, on the Gipping, 12 miles north-west of Ipswich. Iron, leather, paper, and gun-cotton are manufactured. The Gipping is navigable to S. Pop. (1871) 4097; (1881) 4052.

STRABA'NE, a market-town of the county of Tyrone, Ireland, on the river Mourne, 130 miles north-north-west from Dublin, with which it communicates by railway. It communicates with Londonderry, and thus with the sea, by canal and river. The chief industry is connected with the linen trade, and there is also a valuable fishery. S. has four churches—one Protestant episcopal, two Presbyterian, and one Roman Catholic—besides two Methodist meeting-houses. The population in 1881 was 4196.

STRABI'SMUS. See SQUINTING.

STRA'BO, an ancient geographer, born at Amasea in Pontus, about the middle of the 1st c. B.C. By the mother's side he was of Greek descent, and also closely connected with the Mithridatidæ; of his father or his father's family nothing is known. How the name Strabo ('squint-eyed') must have originated, is obvious, but whether any of the family were so called before him is uncertain. S. was well educated under the grammarians, Tyrannio of Amisus in Pontus, and Aristodemus of Nysa in Caria, and the philosopher Xenarchus of Seleucia in Cilicia. He does not appear to have followed any professional calling, but to have spent his life in travel and study, from which it may safely be inferred that he was possessed of wealth, or at least of considerable means. He died sometime after 21 A.D., but how long, we have no evidence to show. S.'s *Geography* is a work of great value in those parts especially which record the results of his own extensive observation. 'Westwards,' he says in a passage in the 2d Book, 'I have travelled from Armenia to the parts of Tyrrhenia adjacent to Sardina; towards the south, from the Euxine to the borders of Ethiopia. And perhaps there is not one among those who have written geographies who has visited more places than I have between these limits.' Yet it must not be supposed that he describes with equal accuracy or fulness all the countries of whose geography he treats.

Some he seems to have visited hurriedly, or in passing elsewhither; others he knows like a native. For example, his accounts of Greece, particularly the Peloponnesus, are meager in the extreme, and of many of the obscurer regions he writes chiefly from hearsay. He makes copious use of his predecessors, Eratosthenes, Artemidorus, Polybius, Posidonius, Aristotle, Theopompus, Thucydides, Aristobulus, and many other writers now lost to us, but he strangely depreciates the authority of Herodotus, and quotes few Roman writers except Fabius Pictor and Julius Cæsar. The *Geography* comprises 17 books, of which the first two are introductory, the next eight are devoted to Europe, the six following to Asia, and the last to Africa. The style is pure and simple. The *editio princeps* of S. appeared at Venice in 1516; the latest and best is that by Gustaf Kramer (Ber. 1844, *et seq.*).

STRADELLA, ALESSANDRO, a Neapolitan musical composer born about 1645; he is famous both in respect of his influence on the music of that age, and of the tragical history of his life and death. His works, which consist of numerous airs, duets, cantatas, madrigals, an oratorio, and an opera, contributed largely to form the taste of the succeeding composers, particularly Purcell, Clari, Steffani, and Alessandro Scarlatti. S. was renowned for his exquisite voice and polished manner; and when engaged in Venice, instructing a young lady of rank, who lived in a criminal intimacy with a noble Venetian, the musician and his pupil became mutually enamoured, fled to Rome, and were married there. They were traced thither by two bravos in the employ of the Venetian, who discovered them in the church of San Giovanni Laterano, where S. was assisting at the performance of an oratorio of his own; and both assassins, it is said, were so captivated with his voice and strains, that they at once abandoned their object, and betrayed to him the plot in which they had been engaged. Pursued by other bravos to Turin, S. was stabbed, but not mortally, when lodged in the palace and under the protection of the Duchess of Savoy. Some years afterwards, however (about 1687), he went to Genoa, in pursuance of an engagement to compose an opera, and the day after his arrival, both he and his wife were mortally stabbed in their bedchamber by the emissaries of their unrelenting persecutor.

STRADE'LLA, a city of Northern Italy, 10 miles south-east of Pavia, with 7193 inhabitants. It is situated on the slope of a hill. S. was formerly a fortified city, depending on the bishops of Pavia.

STRAFFORD, THOMAS WENTWORTH, EARL OF, eldest son of Sir W. Wentworth of Wentworth, Woodhouse, Yorkshire, was born April 13, 1593. In 1611, he married Lady Margaret Clifford, eldest daughter of the Earl of Cumberland. Subsequently, he was chosen member of parliament for the county of York. In 1615, he was appointed *Custos Rotulorum* for the West Riding of the same county. Being again returned to parliament for Yorkshire in 1621, shortly after his election he took up his residence in London. Slighted by the Duke of Buckingham, who then ruled the court and cabinet of Charles I., Wentworth signalized himself as an opposer of the administration. In 1626, he was made sheriff of his county, with the view of preventing him from attending parliament. So resolutely did he oppose the arbitrary royal loan, exacted in the following year, that the government deemed it advisable to put him in prison. But Buckingham was little aware of the energy of his opponent. S., having obtained his release, came to the following parliament, resolved to make his power felt both by king and minister. He spoke eloquently on the question of grievances, and was conspicuous in obtaining the royal assent to the Petition of Right. He was obviously a man worth gaining; and his patriotism, if it had any genuine element, was, unhappily, not strong enough to withstand the temptation now held out to his personal ambition. With his elevation to the peerage, as Baron Wentworth, in 1628, he seems not only to have lost all solicitude for popular liberty, but openly to have become its most determined enemy.

As President of the 'Council of the North,' he seems to have abused his powers not only for political purposes but often simply to gratify his own pride. The legality of the jurisdiction exercised by the council, created by Henry VIII., was altogether very doubtful; and interdicts against it were at various times applied for from the Courts at Westminster. S. declared openly that he would 'lay by the heels' any judge presuming to interdict the council from the exercise of such powers as he chose to hold that it possessed. Nevertheless, this was done by Judge Vernon. In 1631, S. was made Deputy of Ireland, and in 1639, Earl of Strafford and Lord Lieutenant of Ireland. According to his views, that country belonged to the crown by right of conquest, and neither the natives, nor the descendants of the conquerors themselves, had any rights which could interfere with its sovereignty. His government was of despotic violence, but the administration of justice, in ordinary cases, was prompt and vigorous. Outrage was suppressed, and commerce flourished under his strong hand. Understanding fully the feelings, policy, and resources of the party to which he had originally belonged, S. had matured a vast political scheme, to which, in his confidential correspondence, he gave the expressive name of 'Thorough.' His object was to do in England what Richelieu was doing in France—to make Charles as absolute as any continental monarch; to put the estates and personal liberty of the whole people at the disposal of the crown; to deprive the courts of law of all independent authority; and to punish with merciless severity all who murmured against the government, or who applied to any tribunal for relief from its despotism. Happily, the people of England were too strong for him.

On his entering the House of Peers, on the meeting of the Long Parliament in 1640, the message from the House of Commons was called in, and Mr. Pym, in the name of the Commons of England

impeached 'Thomas, Earl of Strafford,' of high treason. This course was afterwards abandoned, and the Commons proceeded by bill of attainder. It passed the House on April 21, 1641. Immediately after, it passed in the House of Lords, and received the royal assent. S. certainly merited his fate, but nothing can excuse the cowardice of the king. The earl was executed on May 12, 1641. The attainder was reversed in the reign of Charles II., and his son succeeded to the honors.—See Hallam's *Constitutional History;* Macaulay's *History of England*, with authorities cited in these works.

STRAIN, the name given to any one of the periods into which a musical composition is divided by double bars, the strain being further subdivided into periods, sections, phrases, and feet.

STRAITS SETTLEMENTS are the British settlements in the Straits of Malacca, comprising Singapore (q. v.), Malacca (q. v.), and the Prince of Wales Island (q. v.), or Penang, including the province of Wellesley. Each of these settlements is described in its own place, and its area and population given. The S. S. were transferred from the control of the Indian government to the colonial secretary in 1867. The seat of government is at Singapore. Area, 1350 sq. m. Pop. (1881) 390,000.

STRA'LSUND, a fortified town and seaport of Prussia, province of Pommern, is situated on a narrow strait called the Strela Sunde, which divides the mainland from the island of Rügen. It forms an island, partly surrounded by the sea, and partly by large pools of salt water, and is connected with the mainland by three bridges. The natural strength of the place is greatly increased by formidable fortications. Right in front of the harbor lies the fortified island of Dänholm. S. has narrow but pretty regular streets, and many of the houses are finely gabled, which gives the town a quaint and ancient look. S. carries on a large export-trade, especially in malt and corn, and has manufactures of leather, sugar, starch, mirrors, and cards. In 1872, 242 ships entered the port. Pop. (1881) 29,481. S. was founded in 1209 by Prince Jaromar of Rügen, became a member of the Hansa, and rapidly rose into importance. During the Thirty Years' War, it was unsuccessfully besieged (1628) by Wallenstein; and after being, with some alternations of fortune, in the possession of Sweden for about 200 years, it finally passed to Prussia in 1815, but still retains much of its ancient municipal independence.

STRANGE, Sir Robert, eminent as an engraver, was born in Pomona, one of the Orkney Islands, July 14, 1721. After some little abortive study of law at Edinburgh, he was apprenticed to an engraver there of the name of Cooper, under whom he made rapid progress. In 1745, he deserted art for arms, joining the army of Charles Edward, not so much from enthusiasm in his cause, as to find favor with a Miss Isabella Lumisden, who would only consent to be gracious to him on that romantic condition. The only exploit recorded of him in this relation is not one of glorious battle. After the final collapse of the adventure, he was in hiding in the house where Miss Lumisden resided; and on occasion of its being searched by the soldiery, he shrouded himself under the folds of her ample petticoat, and thus cleverly evaded detection. It is extremely satisfactory to know that very soon after the lady requited his heroism by marrying him. He now went abroad with his wife, and at Paris he prosecuted his art under the tutelage of the celebrated Le Bas, and afterwards of Descamps. In 1751, he returned to Britain, and settling himself in London, speedily attained the very highest rank in his profession. On again going abroad in 1760 to execute plates of the most famous pictures of the old masters, his eminence was recognized by the academies of Paris, Rome, Florence, Bologna, and Parma, all of which conferred on him the honor of membership; and subsequently in 1787, the distinction of knighthood testified to the high favor he found in his own country. After a life of honorable and successful industry, he died on 5th July 1792, leaving a handsome fortune to his family. To this day, S. is ranked at the very head of British engravers, and his reproductions of the nobler specimens of the old masters are much prized by the connoisseur. In the very amusing work entitled *Memoirs of Sir Robert Strange, Knight, Engraver, and of his Brother-in-law, Andrew Lumisden, Private Secretary to the Stuart Princes* (2 vols. 1855), by James Dennistoun of Dennistoun, a full account will be found of him, with an intelligent criticism of his chief works.

STRANGLES is a contagious eruptive disorder peculiar to young horses. It is ushered in by sore throat and cough, a muco-purulent nasal discharge, and the eruption of a swelling in the space between the branches of the lower jaw. In about ten days this swelling comes to a head, bursts, and in favorable cases the patient is soon well again. From exposure to cold, poverty, or other causes, the swelling, however, occasionally appears in less favorable situations, as about the glands lying within the shoulder, in those of the groin, or even in those of the mesentery. Such irregular cases are apt to be protracted, accompanied by much weakness, and sometimes prove fatal. Bleeding, physic, and irritant dressings are injurious. Good food and nursing, with fomentations to the throat, and steaming of the head, favor the healthier maturation of the swelling. When there is debility, coax the animal to eat by offering him at short intervals small quantities of scalded oats, malt, bran, or green food, and allow him several times daily a pint of sound ale.

STRANGULATION may be defined to be 'an act of violence in which constriction is applied directly to the neck, either around it, or in the fore part, so as to prevent the passage of air, and thereby suddenly suspending respiration and life.'—Taylor's *Principles and Practice of Medical Jurisprudence*, 1865, p. 673. This definition, as Dr. Taylor observes, obviously includes Hanging (q. v.). *Hanging* has been already briefly noticed in a special article, but the medico-legal relations of this and the other varieties of strangulation have still to be considered. The primary cause of death from hanging has been considered in the article just referred to, but it is necessary to add that if a person who has hanged himself has been cut down sufficiently soon to allow of the respiratory process being restored, he is by no means safe: death often taking place from secondary effects at various periods after the accident. The most prominent morbid appearance in these instances was extreme congestion of the brain.

When the suspension of the body has not continued for much more than five minutes, and the parts about the neck have not suffered violence, there is a probability that resuscitation may be established; although many cases are recorded, when after only a few minutes' suspension, it has been found impossible to restore life. It is believed that death takes place very rapidly, and without causing any suffering; the violent convulsions that are so often observed being similar to those which occur in epilepsy. A man named Hornshaw, who was on three occasions resuscitated from hanging—a feat which he performed in London for the amusement of the public—stated that he lost his senses almost at once; and other persons who have been restored state that the only symptoms of which they were conscious were a ringing in the ears, a flash of light before the eyes, then darkness and oblivion. The treatment to be adopted after the patient has been cut down may be briefly summed up as follows: Exposure to a free current of air, cold affusion if the skin is warm, the application of ammonia to the nostrils, of mustard poultices to the chest and legs, and of hot water to the feet, and the subsequent abstraction of blood if there should be much cerebral congestion; artificial respiration should also be tried if the above means fail to re-establish the respiratory process. From the post-mortem appearances, together with circumstantial evidence, the medical practitioner is not unfrequently called upon to decide such questions as these: Was death caused by hanging, or was the body suspended after death? Was the hanging the result of accident, homicide, or suicide? For the full discussion of these questions, the reader is referred to chapter 53 of Dr. Taylor's volume. In case of strangulation from other causes than that of hanging, the post-mortem symptoms are similar, but the injury done to the parts about the neck is commonly greater. In manual strangulation, the external marks of injury will be in front of the neck, about and below the larynx; and if death has been caused by a ligature, the mark round the neck will be circular, whereas in hanging it is usually oblique. The internal appearances are much the same as in the case of hanging.

STRA'NGURY (Gr. *strangx*, that which oozes out, *oureo*, I micturate) is perhaps to be regarded as a symptom rather than a disease. It shows itself in a frequent and irresistible desire to pass water, which is discharged, however, in very small quantity, and whose passage from the bladder is accompanied with scalding and cutting pains along the course of the urethra. The pain often extends to the bladder and even to the kidneys, and is sometimes so severe as to implicate the lower bowel (the rectum), and to produce the straining condition known as *Tenesmus*. It is usually caused by irritating substances in the urine, especially by *cantharides* or Spanish flies (whose irritant principle is liable to find its way into the renal secretion, whether the above-named drug is taken internally or merely applied to the skin as a blistering agent), and by oil of turpentine, when administered internally in small doses, and is generally present in cases of gravel. Severe as the affection is, it is very transitory, and yields readily to treatment. After the removal of the cause, if it can be recognized and the removal is possible, a drachm of laudanum in a wine-glassful of starch mucilage should be thrown into the lower bowel, and mild mucilaginous draughts (of barley-water, for example) should be freely given in order to render the urine less irritating. The warm bath is also useful, and if it cannot readily be obtained, hot local fomentations often tend to relieve the pain and allow the urine to pass more freely.

STRANRAE'R, a royal and parliamentary burgh, seaport, and market-town, of Wigtownshire, at the head of Loch Ryan, 6 m. N.-E. of Portpatrick. There are no manufactures, the town de-

pending almost wholly on the agricultural interest. The oyster fishery in Loch Ryan was at one time very productive, but has latterly fallen off greatly. A mail-steamer runs daily between S. and Larne, in Ireland. Upwards of 1200 vessels annually enter and clear the port. Agricultural produceand cattle, leather, and shoes are exported. Pop. of royal burgh (1871) 3615, of parl. borough, 5941; of parl. borough (1881) 6342. S. is one of four Wigtown burghs which unite to send a member to parliament.

STRAP, in Carpentry, an iron band fixed round two or more timbers, sometimes with branches along each, to hold them all firmly together.

STRA'SBOURG (Ger. *Strassburg*), a fortified town, formerly the capital of the French department of the Bas-Rhin, but, since 1871, capital of the new German Province of Alsace-Lorraine, stands at the confluence of the Ill and the Brusche, and not far from the left bank of the Rhine, 89 miles north of Basel, and 312 miles east of Paris by rail. The citadel, originally built by Vauban, 1684, was demolished by the Germans during the bombardment of 1870, but in 1873 they began to rebuild it, and this in conjunction with a system of 12 detached forts, being erected at several miles' distance from the walls, will make the position one of great strength. The most celebrated building is the minster, or cathedral, founded in 1015, which is one of the most sublime specimens of Gothic architecture. Of the two western towers one, that at the south corner, has not been completed. The other, finished in 1399, rises, according to Baedeker, to a height of 495 feet above the pavement—14 feet higher than the original top of the Pyramid of Cheops, while the towers of Cologne Cathedral rise to a height of 512 feet. The minster has a remarkable astronomical clock representing the planetary system. Other notable structures are the Protestant church of St. Thomas, with the tomb of Marshal Saxe, and various monuments to distinguished S. scholars; the *Temple Neuf*, or New Temple, the synagogue of the Jews, the Town-house, the Palace of Justice, the arsenal, the episcopal palace, and the theater. The university of S. was the only complete university in France—i. e., the only one which has the full complement of faculties—besides that of Paris. It was founded in 1621, became specially famous in the branches of medicine and philology, went to the ground during the great Revolution, and had its place supplied by an *Ecole Centrale*.

In 1803, a Protestant academy was established with 10 chairs, for teaching theology, philology, philosophy, and history. Five years later, Napoleon founded an imperial academy, with faculties of law, medicine, physical science, and philosophy; and in 1819, a partial fusion of these academies took place, greatly to the benefit of both. The university was reopened in 1872, after the war, as the Kaiser Wilhelm University. In 1882 it had 104 professors and 825 students (of whom 216 were from Alsace-Lorraine). The famous library of S., consisting of nearly 200,000 volumes, and rich in *Incunabula* (q. v.), was entirely destroyed by fire during the bombardment in 1870, but was replaced by a new collection that has now swelled to over 525,000 volumes. The trade of S., especially its transit-trade, is very extensive, and it has a great variety of manufactures—beer, ham, sausages, fat-liver pies, watches and clocks, leather, cottons, woollens, silks, cutlery, musical and mathematical instruments, jewelry, brandy, potash, tobacco, &c. The Basel and Baden railways, the railway to Paris, and the communication with Rotterdam and London by means of the Rhine steamers, as well as with the Danube and all the great rivers of France by means of canals, have greatly added to its facilities for conducting commerce. The country round about S. is fertile and carefully cultivated, with beautiful gardens, mansions, and villages. Pop. (1871) 85,529; (1880) 104,471, of whom about one-half are Catholics.

S., the *Argentoratum* of the Romans, was extant before the time of Cæsar, but is first mentioned by Ptolemy. The Romans had a manufactory of arms here. In the 5th c., it appears to have received the name of *Strata-Burgum* or *Strata-Burgus*, perhaps from the invading Franks, whence the modern German Strassburg and the French Strasbourg. It became a free town of the German Empire, and in 1681 passed with the rest of Alsace into the hands of the French, under whom its population and prosperity greatly increased. On Sept. 28, 1870, after a bombardment of seven weeks, S. surrendered to the Germans, and in 1871 was annexed to Germany.

STRA'TEGY is defined by military writers to be the science of manœuvring an army out of fire of the enemy, as *tactics* is the art of managing it in a battle, or under fire. Strategy is the greater science, as including all those vast combinations which lead to the subsequent available displays of tactics. A good strategist has to attend to the establishing of his bases and dépôts, although some brilliant generals have dared to act without these last aids—notably, Sherman in America in 1864, and Wellington in 1813, advancing from Portugal through Spain into France. The strategist must know how to diffuse the influence of his arms over a broad area, while yet holding his force well in hand to strike crushing blows. Such was Wellington's Salamanca campaign; in which, though retreating himself to his former base, he compelled the French to evacuate Valentia.

Strategy must not be confounded with stratagem, although there is relationship between the two. Stratagem is any device for deceiving the enemy as to the point or strength of an attack. Such are ambuscades, feints, bugle-calls to imaginary troops, concealment of infantry by clouds of cavalry, and many other efforts.

STRA'TFORD, a thriving town of Essex, on the Lea, 3 miles east of London. It is the seat of various and extensive manufactures. There are flour-mills, distilleries, and chemical works. In the town and its suburbs, many London merchants have built residences. The prosperity of the town has been much increased by its connection with the Eastern Counties Railway. Pop. (1851) 10,586; (1871) 23,286; (1881) 38,489. On the opposite side of the Lea is the parish of Stratford-le-Bow, or Bow, with (1871) 26,055 inhabitants.

STRATFORD-UPON-AVON, a municipal borough and township of England in the county of Warwick, and 8 miles southwest of the town of that name, is situated on the right bank of the Avon. Pop. (1871) 3863; (1881) 8053. The town is neatly built, and has quite a modern look, most of the old houses having disappeared. Some trade is carried on in corn and malt. S. is the birthplace of Shakspeare. The house in which he was born is still preserved, and there is a Memorial Theater, with library and picture-gallery, in honor of the poet. The great poet is buried in the parish church.

STRATFORD-DE-REDCLIFFE. STRATFORD CANNING, VISCOUNT, English diplomatist, was the son of a London merchant, and cousin of the celebrated George Canning. He was born 1788, educated at Eton, and entered himself of King's College, Cambridge, in 1806, but left in 1807, on receiving an appointment as précis writer in the Foreign Office. He was appointed secretary of embassy at Constantinople in 1809. He returned to Cambridge in 1812 for the purpose of resuming his studies, and took the degree of M.A. He was sent as envoy to Switzerland in 1814. About this time he published an ode full of spirit and power, entitled *Buonaparte*. It is called by Lord Byron a 'noble poem.' In 1820, he went as plenipotentiary to the United States, and remained at Washington three years. In 1824, he was sent on special missions to St. Petersburg and Vienna. In 1825, his introduction to Eastern diplomacy commenced with his appointment by Mr. Canning, then foreign secretary, as ambassador extraordinary to the Sublime Porte. Here his good offices were warmly exerted on behalf of the Greeks. In 1831, he was accredited with a special mission to Turkey, to fix the boundaries of the new kingdom of Greece, and to settle the treaty in virtue of which Otho ascended the Greek throne. He went to Madrid and Lisbon on a special mission in 1832. He had previously sat in the House of Commons for Old Sarum and Stockbridge during a brief interval in his diplomatic career. In 1834, he was elected for King's Lynn, which he represented until 1841, when, having twice refused the governor-generalship of Canada, he was appointed by the government of Sir Robert Peel ambassador at Constantinople. Here his influence was strenuously exerted in the cause of civilization and progress.

In 1852, the Derby administration recommended the crown to confer upon him the title and dignity of Viscount. When the long-standing quarrel between the Greek and Latin monks in Palestine involved the powers of Europe in the struggle, S. remembered how the Emperor Nicholas of Russia had, from 1829 to 1853, sought to establish a predominant influence, excluding all others, over the Porte, with the view of settling the future destinies of Turkey, to the profit of Russia when the propitious juncture arrived. At the time when Prince Menchikoff was sent to Constantinople upon a mission from the czar, S. was absent in England on leave. He returned to Constantinople in April 1853, and prepared to resist M.'s demands. The keenly contested diplomatic struggle between S. and the Russian ambassador extraordinary is narrated with dramatic power by Mr. Kinglake in his *Invasion of the Crimea*, who calls S. the 'Great Eltchi.' S.'s influence with the Porte prevailed, for, to adopt the words of Mr. Kinglake, 'as though yielding to fate itself, the Turkish mind used to bend and fall down before him;' and he placed on England the responsibility of a defensive alliance with the sultan against the czar. As Russia would not withdraw her troops from the principalities, the sultan declared war against Russia, and France and England came to the aid of the Porte. S. retired from the Turkish embassy in 1858 upon a pension. He afterwards took a frequent part in the debates of the Upper House on questions of foreign policy. S. was created a Knight of the Garter in 1869; he died Aug. 14, 1880. In 1873 he published *Why am I a Christian?* and in 1876 a play, *Alfred the Great in Athelney*.

STRATH, a Gaelic word signifying a broad valley, is often prefixed in the north of Scotland to the names of rivers, as

Strathearn, Strathallan, Strathmairn, Strathspey, in each of which cases it signifies the open valley through which the river flows. In such cases, however, as Strathmore (great valley), it simply signifies a valley-like depression. In the south of Scotland, the word is not used, the Northumbrian word *dale* being used instead, as Clydesdale, Annandale, Teviotdale, Tweeddale.

STRATHA'VEN, a town of Scotland, in Lanarkshire about a mile W. of Avon Water, and 14 miles S. E. of Glasgow. On the north side is the picturesque ruin of Avondale Castle, and from 5 to 7 miles south-west are the battle-fields of Drumclog and Loudoun Hill. The more recently built part of the town is neat and spacious. Pop. (1881) 3812, chiefly engaged in weaving and trading in cheese and cattle.

STRATHCLY'DE. In the 8th c., the ancient confederacy of the Britons was broken up into the separate divisions of Wales and English and Scottish Cumbria. Scottish Cumbria, otherwise called S., thenceforth formed a little kingdom, comprising the country between Clyde and Solway, governed by princes of its own, and having the fortress-town of Alclyde or Dumbarton for its capital. Becoming gradually more and more dependent on Scotland, it was annexed to the Scottish crown at the death of Malcolm I., on failure of the line of native sovereigns. Edgar bequeathed S. to his youngest brother David, again separating it from the crown of Scotland, which went to his intermediate brother, Alexander I. David held it throughout Alexander's reign in spite of that king's opposition, and on Alexander's death without issue in 1124, it was permanently reunited to the Scottish kingdom under David I.

STRATHMO'RE (the Great Valley), the most extensive plain in Scotland, is a low-lying tract extending across the country from Dumbartonshire north-east to Stonehaven in Kincardineshire, is bounded on the north by the great mountain-rampart of the Highlands, and on the south by the Lenox, the Ochil, and the Sidlaw Hills, and is 100 miles long and from 5 to 10 miles broad. S. proper, however, extends only from Perth to near Brechin in Forfar (about 40 miles).

STRATHPEFFER, a valley and watering-place in Ross-shire, 4¼ m. west of Dingwall by rail. There are two chief wells, and a pump-room.

STRATHSPEY', a kind of Scottish national dance slower than the reel, which is said to derive its name from having been first practised in the district called Strathspey.

STRATIO'TÉS, a genus of plants of the natural order *Hydrocharideæ*. *S. aloides*, popularly WATER SOLDIER, is common in lakes and ditches in the east of England. It is a singular plant with numerous leaves, which are strap-shaped and spring from

Water Soldier (*Stratiotes aloides*).

the root, from which also springs the two-edged flower-stem, bearing the spathe with beautiful and delicate white flowers. In autumn the whole plant disappears, the root alone remaining at the bottom of the water; from which a number of young plants arise in spring, filling up ditches, so that nothing else can grow in them. It is a very ornamental aquatic plant.

STRA'TUM, pl. *strata* (Lat. strewn or spread out), the term applied by geologists to the layers into which most of the rocks that form the crust of the earth are divided. It implies that the layers have been spread out over the surface, and that they were formed in this way we may infer from the deposits that are now taking place in lakes and seas into which rivers laden with muddy sediment empty themselves.

All the aqueous rocks, which cover so large a proportion of the earth's surface, are stratified. They were formed from the abraded materials of older rocks (aqueous or igneous), which have been washed down and rearranged. The kind of rock produced depended upon the material to which the carrying agent had access. Fine mud would produce shales, sand sandstones, and calcareous matter limestones. In a section, these different kinds of rocks are frequently found to interchange within a short space. This is produced either by the water obtaining different materials, or changing its velocity. Thus the fine sediment which has fallen from slowly flowing water may be covered by a layer of sand brought down by a flood, and this again may have spread over it a covering of shells and corals, and such changes may go on alternately for an indefinite period. Each of the different beds composed of the same kind of material is called a stratum. Thus, in the series mentioned, there would be a 'stratum' of clay, one of sand, and then one of calcareous matter. An assemblage of strata having a common age is called a 'formation,' and this term is also extended to rocks which agree in their composition or origin. Thus we speak of stratified and unstratified, aqueous and igneous, freshwater and marine, primary and secondary, metalliferous and non-metalliferous formations. As a formation is composed of many different beds, so a stratum is frequently made up of several 'laminæ' or 'layers.' The laminæ have a more or less firm cohesion, but the strata easily separate from each other. Sometimes the cohesion of the laminæ is so great, that it is as easy to split the rock against as with the grain. In such compact rocks the lamination is obscure, or altogether imperceptible in fresh specimens, but whenever they are exposed to the influence of the weather, it becomes obvious. The laminæ have been produced by short interruptions in the deposition, similar to what might be the result of tidal or other intermittent action. The degree of cohesion may be the result of rapid succession in the acts of deposition, but it is frequently produced by metamorphic action subsequent to deposition. The planes of stratification want the complete coalescence characteristic of lamination; when the contiguous layers are closely united, it is the result of the adhesion of two bodies, and not of their coalescence into one.

STRAU'BING, a town of Lower Bavaria, on the right bank of the Danube, 25 miles south-east of Ratisbon, lies in a very fertile valley, and carries on a river-trade in corn, cattle, and horses. In a little chapel here there is a monument to Agnes Bernauer (q. v.). Pop. (1880) 12,625.

STRAUSS, DAVID FRIEDRICH, author of the famous *Leben Jesu*, was born on the 27th January 1808, at Ludwigsburg, in Würtemberg. His education was begun in his native town, and completed in the theological seminaries of Blaubeuren and Tübingen. In 1830, his head filled with Hegel's philosophy and Schleiermacher's theology, he entered on the simple life of a country pastor, but already in the following year he was in Maulbronn acting as professor in the seminary, and went thence to Berlin for six months to continue his Hegelian studies, and hear the lectures of Schleiermacher. Returning to Tübingen in 1832, he became *repetent* in the theological seminary, and in the next years held also philosophical lectures in the university as a disciple of Hegel. Known as yet only to a narrow circle, he became all at once a man of mark by the publication, in 1835, of his *Life of Jesus critically treated* (2 vols. Tüb.; 4th ed. 1840; translated into English, 1846). In this work, written from the point of view of a Hegelian philosopher, and designed only for the learned, he attempted to prove the received gospel history to be a collection of myths gradually formed in the early Christian communities, and sought, by an analytical dissection of each separate narrative, to detect, where it existed, a nucleus of historical truth free from every trace of supernaturalism. The book made a real epoch in theological literature, and produced a violent excitement in and out of Germany, calling forth numberless replies from opponents, frightening many by its bold disregard of consequences back into the ranks of orthodoxy, and stirring up others to similar investigations.

The first consequence to the author was his dismissal from his academical position in Tübingen, and transference to the Lyceum of Ludwigsburg. He resigned the new post, however, very soon in 1836, and retired into private life at Stuttgart, to have leisure to defend himself. In 1837, he published his *Streitschriften* against his opponents; and in 1838, *Zwei friedliche Blätter*, a more conciliatory exposition of his views. Early in 1839, he was called by the Board of Education in Zürich to be Professor of Dogmatics and Church History in the university; but the step raised such a storm of opposition amongst the public, that the proposition had to be dropped, and even the government itself had to resign in the same year. Thrown back on his literary labors, S., who had published during the year his *Charakteristiken und Kritiken*, sent forth shortly afterwards his second great work, *Die Christliche Glaubenslehre*, a review of Christian dogma 'in its historical development and its struggle with modern science' (Tüb. 1840—1841). This formed a natural sequel to the purely critical investigation of the origins of Christianity in the first work. When S., after a long

period of silence, next appeared on the literary field, it was no longer as a professed theologian. In 1847, he drew attention by a work entitled, *Der Romantiker auf dem Throne der Cäsaren, oder Julian der Abtrünnige*, full of direct allusions to the political situation of the day. His fellow-townsmen put him forward as a candidate for the German revolutionary parliament of 1848, but he was unable to stand against the clerical influence brought to bear upon the country-people of the district. His speeches on this occasion were published under the title of *Six Theologico-political Popular Addresses*, and his native place compensated the defeat by sending him as its representative to the Würtemberg Diet. From this position, however, when he unexpectedly displayed conservative leanings, and incurred a vote of censure from his constituents, he retired before the end of the year.

A life of the Swabian poet Schubart (1849), and another biographical work, *Christian Märklin, a Picture of Life and Character from the Present* (1851), giving an insight into his own mental development, were his next literary efforts, before another period of silence. His third period of activity was opened in 1858 by a remarkable life of the Reformer, Ulrich von Hutten (Eng. trans. 1874), followed up by the publication of Hutten's *Dialogues* in 1860. These books, though primarily of strictly historical interest, were nevertheless calculated for the present state of religious affairs in Germany, and contained fiercely contemptuous denunciations of the tactics of the reactionary party in the church. A collection of miscellaneous *Minor Writings* appeared in 1862, and a new *Life of Jesus, composed for the German People*, in 1864 (Eng. translation, 1865). The title of the work indicates its popular cast, the peculiar features of it being a long critical statement of the labors of others in the same field down to the present day, and an attempt to construct a life out of all the positive results that have been gained. The mythical hypothesis is retained, but applied differently. Still later publications, which appeared in 1865, are *Der Christus des Glaubens u. der Jesus der Geschichte* (Berlin), a criticism of the newly published lectures of Schleiermacher on the life of Jesus, and a brochure, *Die Halben u. die Ganzen*, directed against Schenkel and Hengstenberg. The polemic against Schenkel, Professor of Theology in Heidelberg, a leader of the liberal party in the church of Baden, and author of the *Charakterbild Jesu* (1864), arose out of an earlier notice of this book by S. In 1872, he published his last work, *Der alte und der neue Glaube*, in which he endeavors to prove that Christianity as a system of religious belief is practically dead, and that a new faith must be built up out of a scientific knowledge of nature. S. died in 1874. An edition of his collated works (*Gesammelte Schriften*) began to be published in 1876. The literary, critical, and polemical powers of S. must be pronounced to be of the highest order. No more effective German prose than his has been written since Lessing.—See *Life of S.* by E. Zeller (Eng. trans. 1874).

STRA'WBERRY (*Fragaria*), a genus of plants of the natural order *Rosaceæ*, suborder *Roseæ*, tribe *Potentillidæ*, remarkable for the manner in which the receptacle increases and becomes succulent, so as to form what is popularly called the fruit; the proper fruit (botanically) being the small *achenia* which it bears upon its surface. The genus differs from *Potentilla* (q. v.) chiefly in having the receptacle succulent. The calyx is 10-cleft, the segments alternately smaller; the petals are five; the style springs from near the base of the carpel. All the species are perennial herbaceous plants, throwing out runners to form new plants; and the leaves are generally on long stalks, with three leaflets, deeply toothed. One South American species has simple leaves. Only one species, the WOOD S. (*F. vesca*), is truly a native of Britain. It is common in woods and thickets. Its fruit is small, but of delicious flavor. Another species, the HAUTBOIS S. (*F. elatior*), is not unfrequently to be seen in woods and hedges, but has probably escaped from gardens. It is really a native of North America. The many kinds cultivated in gardens are regarded as varieties of these species, and of the CAROLINA S. (*F. caroliniana*), the PINE S. (*F. grandiflora*, or *F. ananas*), and the CHILI S. (*F. chilensis*), American species, the leaves and fruit of which are larger than those of the Wood Strawberry. In no genus, however, are the species more uncertain to which the cultivated kinds are to be referred. Some of these are remarkable for the large size of the fruit. New varieties are continually coming into notice, and the utmost care is necessary to keep the larger and finer varieties from degenerating. The cultivation of the S. is most extensively carried on in Britain and in Belgium. New kinds are produced from seed; but plantations of strawberries are generally formed of the young plants, which are abundantly produced by runners. The rows are from eighteen inches to two feet apart, according to the kind. The finest fruit is said to be produced when the plants are kept distinct from each other in rows, but this is not generally done.

Tiles are sometimes placed around the plants and under the fruit; and it is an old English practice to lay straw between the rows, to preserve the fruit from rotting on the wet ground, from which the name S. has been supposed to be derived; although more probably it is from the wandering habit of the plant, *straw* being a corruption of the Anglo-Saxon *strae*, from which we have the English verb *stray*. S. beds require to be renewed after a few years. Strawberries are often forced in hothouses, in order to produce the fruit at a very early season. The uses of the S. as a dessert fruit and for preserves are well known. There is no more wholesome fruit.

The ALPINE S. (*F. collina*), a native of Switzerland and Germany, differs considerably from the other kinds in its taller stems and more erect manner of growth. The fruit, which is either red or white, is not very large, but is produced in great abundance, and, unlike other strawberries, parts from its calyx almost on being touched. The Alpine S. continues to produce fruit long after the other kinds.

The INDIAN S. (*F. indica*), a native of the Himalaya, requires only a little protection in Britain from severe frost, and with this care grows luxuriantly and produces fruit in abundance. The flowers are yellow, not white, as in other strawberries, and are not produced upon common flower-stalks, rising from the center of the plant as in the other species, but upon single-flowered stalks, which spring from the axils of the leaves upon the runners. The fruit is very beautiful, growing with its apex upwards. It is not, however, of good quality.

STRAW-MANUFACTURES. The industrial applications of the straw of wheat are of great commercial importance, especially that of plaiting, which is one of the oldest arts practised by mankind, many specimens having been found in the tombs of the ancient Egyptians, and mention being made of plaiting by Herodotus and other early writers. The earliest notice we have of its systematic use in Europe as an article of clothing is in the records of the reign of Mary, Queen of Scots, who, we are told, observed that the peasants of Lorraine wore hats made of straw plait, and that this manufacture was beneficial to them, and she consequently conceived the idea of introducing it into Scotland, which was done about the year 1562, but without much success. Her son, James I., however, carried it into England, where it soon throve, and has been from that time a permanent branch of industry. It was first regularly established in Bedfordshire, which has ever since been the chief seat of the trade.

At first, the plait was what is called *whole straw;* that is, the straw was cut into suitable lengths without knots, and merely pressed flat during the operation of plaiting, and so it continued until the reign of George I., when it was in great demand for ladies' hats, and some plait was made of split straw. Since that time, this kind has been chiefly used, and a much improved method has been substituted for the clumsy one of using a common knife for splitting it. The instrument now employed (fig. 1) is made of steel, and consists of a number of little square blades set in a circular manner around the stem, which at one end terminates in the point *a*, and at the other is bent and fixed into the handle *b*. The point, *a*, being inserted into the hollow of the straw, is pressed forward, and cuts it into as many strips as there are blades in the cutting-tool; these vary in number according to the fineness of the work to be produced.

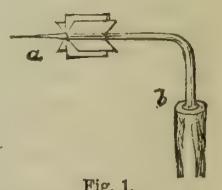

Fig. 1.

It is found that the fine straw-plaiting, which is now produced better in England than in any other country except Italy, can only be made from one or two varieties of wheat, that called the White Chittim being generally preferred, and next to it the Red Lammas, which only succeed as a straw-crop upon the light rich soils of the more southern of the midland counties. The harvesting is a matter of great anxiety, as the straw is liable to many injuries from wet and other causes. The value of this crop can be best understood by the fact that an acre will yield from 25 to 40 bushels of wheat, and from 15 cwts. to a ton of straw, which, when in good condition, is worth £7 or £8.

The crop is bought up by straw-factors, who employ people to draw the straw, and remove the ears, which are all cut off by hand for thrashing. The straws are afterwards cut into lengths, and

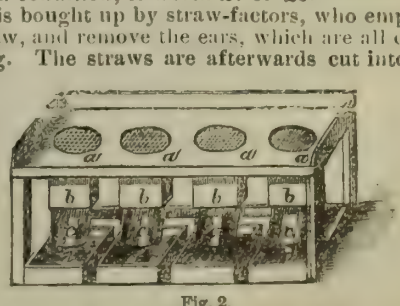

Fig. 2.

cleared of the outer sheath or leaf; they are then sorted into various thicknesses by an apparatus consisting of a series of sieves about eight inches in diameter, arranged as in fig. 2. *a, a, a, a;*

the boys who usually do this work hold a handful on end over the first sieve, which has the narrowest spaces, and the thinnest straws only fall through it; they are next placed on the second, and so on to the last. As they fall through each successive sieve, they pass down the hollow shafts *b*, *b*, *b*, *b*, by the shoots of tin or sheet-zinc *c*, *c*, *c*, *c*, into the boxes *d*, *d*, *d*, *d*, from which they are removed and tied into bundles ready for the splitters, who next take them in hand and reduce them to strips of the sizes required.

The plaits are made by women and children in their own cottages, and are collected by the dealers and sold in the Luton and Dunstable markets, in which the chief part of this business is transacted. They are very various in pattern, and are sold by the *score* of 20 yards, the prices ranging from 2*d*. to 3*s*. per score for the ordinary kinds, but very fine plaits have been known to fetch as high as £3 to £4 per score.

It is computed that 70,000 persons are employed in this trade, of whom nearly 60,000 are females and boys, and that they produce annually about 12,000,000 scores, or 240,000,000 yards of plait. The plait is made up into bonnets and hats chiefly at Luton and Dunstable, and sent up to the London warehouses for sale, whence they are sent to all parts of the world. A large trade is also done in the fine plaits of Tuscany; the Leghorn plaits are very fine, and fetch high prices.

Besides its value for plaiting, straw is now much used in the manufacture of Paper (q. v.).

STRELITZ, more properly *Streltzi* (arque-bussiers), the ancient Russian militia-guard, first raised by Ivan Vassilevitch the Terrible, in the second half of the 16th century. At that time, and for long afterwards, they were the only standing army in Russia, and at times amounted to between 40,000 and 50,000 men. They were located at Moscow in time of peace, in a quarter of the capital which was set apart for them, and being the bravest and most trustworthy troops in the army, were made objects of special favor and distinctions. But like all such petted corps, the Roman Prætorians, the Turkish Janizaries, and the Egyptian Memluks, their general turbulence, frequent revolts against the government (notably during the Demetrian insurrections), and incessant conspiracies rendered them more formidable to the Russian government than to external enemies. The S. having, at the instigation of the Grand Duchess Sophia and the chiefs of the Old Muscovite party, revolted against Peter the Great, that iron-handed ruler caused them to be decimated (1698) in the great square of Moscow, and the remainder to be banished to Astrakhan. The feeble remnant still manifesting their characteristic turbulence and disloyalty, Peter exterminated them almost completely in 1705. Few Russian families at present can claim kindred with the old Streltzi, but to this the family of Orloff (q. v.) forms a prominent exception, being descended from a Strelitz who was pardoned by Peter the Great while the axe was being raised over him.

STRENGTH OF MATERIALS. The strength of materials depends upon their physical constitution—viz., their form, texture, hardness, elasticity, and ductility.

The resistance of materials in engineering works is tested in reference to various strains; such are—1. Extension or tension; 2. Compression or crushing; 3. Transverse or cross strain; 4. Shearing strain; 5. Torsion or twisting strain.

1. *Extension.*—When a rod is suspended vertically, and a weight attached to its end tending to tear it asunder, all its fibres act equally, and its strength evidently depends on the strength of the individual fibres and their number, that is, the area of cross-section of the rod. The following table gives the resistance to *rupture* of some of the most common materials:

	Per Square Inch.	
Fine sandstone	200	lbs.
Brick	300	"
Common lime	50	"
Portland cement	240	"
Deal (timber)	5	tons.
Cast iron (ordinary)	6½	"
" Stirling's (toughened)	12½	"
Wrought iron, boiler-plate	20 to 24	"
" bars	25	"
Cast steel	60	"

Ropes (hemp), four-fifths ton per pound-weight per fathom.

With regard to the elongation of materials under tensional strain, it has been observed that up to a certain limit, which is different for different substances, the elongation is proportional to the extending force, a physical truth the promulgation of which is due to Hooke (q. v.); up to this limit also the body nearly recovers its original form on the removal of the force: this limit is called the limit of elasticity. When this limit is passed, the permanent elongation or destruction rapidly increases until rupture takes place.

The extension of wrought iron is about $\frac{1}{10,000}$th of its length per ton of strain per square inch, and that of cast iron $\frac{1}{5000}$th. The limit of elasticity of wrought iron is attained under a strain of 12 tons per square inch; and in the case of American pine 1½ ton per square inch.

2. *Compression or Crushing Strain.*—The strength of pieces of stone, wood or iron, whose height is small in proportion to their area, and which absolutely crush under the strain, is proportional to the area of their horizontal section. The following table gives the resistance to crushing of some of the more common materials:

Cast iron	50	tons per	square inch.
Wrought iron	16	"	" "
Brickwork	30	tons per	square foot.
Sandstone	200	"	" "
Limestone	490	"	" "
Deal	450	"	" "
Oak	650	"	" "

Up to a certain strain, which is called the limit of elasticity, the diminutions in length of the body are proportional to the compressing force; and are practically the same in amount as the elongations in the case of tensional forces. In the case of wrought iron, the limit is 12 tons per square inch; after that strain its shape and proportions become permanently altered; and where these are of consequence, as in most practical cases, we come to the limit of its utility, which is reached when the load is about 16 tons per square inch. It then oozes away beneath additional strain, as a lump of lead would do in a vice.

The mode of ultimate failure of cast iron is quite distinct from that of wrought iron. It crushes suddenly by the sliding off of the corners in wedge-shaped fragments, being a crystalline mass, without sufficient ductility to allow of its bulging horizontally; the angle of rupture at which these wedges slide off being tolerably constant and varying from 48° to 58°. The limit of elasticity is attained in cubes of deal under a compression of 100 tons per square foot; and in those of oak 150 tons per square foot.

Pillars, round or square, may be divided into three classes—1. Those whose height is not more than 5 times their diameter; 2. Those whose height is between 5 and 25 times their diameter; 3. Those whose height is at least 25 times their diameter. The first follow the same laws as cubes or pieces of small height above discussed, and are absolutely crushed; their strength being proportional to their cross section. The second are broken across, partly by crushing and partly by bending. The third give way purely from bending as with a transverse strain, and their strength is found by experiment to be directly proportional to the fourth power of their diameter, and inversely proportional to the square of their length. Thus, in the case of two long pillars of equal length, but of which one has its diameter double that of the other, the strength of the former will be 16 times that of the latter; from which will be apparent the advantage of the tubular form for pillars, as it gives a large diameter, combined with lightness.

In the case of long columns whose length is 25 or more times their diameter, if we represent the strength of a long cast-iron column of any dimensions by 1000, the strength of a wrought-iron column of the same dimensions will be 1750; of cast steel, 2500; of Danzig oak, 110; of red deal, 80.

3. *Transverse or Cross Strain.*—When a beam fixed at one end is loaded with a weight at the other, it is bent from its original form, and takes a curved shape. The fibers on the upper or convex side of the beam are extended, and those on the under or concave compressed; while at the middle of the beam, there are fibers which are neither extended nor compressed, where the compression ends and the extension begins: this surface of fibers is called the neutral surface. As long as the beam is not strained beyond the limit of its elasticity, the extensions and compressions for a given strain are nearly equal, and therefore the neutral surface passes through the center of gravity of the cross section of the beam.

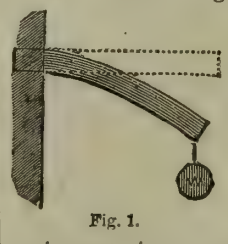

Fig. 1.

If we strain the beam beyond this limit, and approach the breaking strain, the extensions and compressions are no longer equal, and therefore the position of the neutral surface is not readily determined. For example, in the cases of stone and cast iron, the amount of compression is much less than that of the extension, and in the case of timber, greater. Also the extensions and compressions are no longer proportional to the strains. From these causes the position of the neutral axis, and the amount of strain on the different parts of the cross section at the moment of rupture, cannot be determined by theory.

Different theories have been proposed to determine the relative strength of similar beams, while their absolute strength is left to experiment. That of Galileo consists in supposing the beam in-

compressible, and that it gives way by extension turning round the lower edge, each point of the section giving an equal resistance before rupture. That of Mariotte and Leibnitz supposes the beam in like manner to turn round its lower edge, but considers that the resistance given out by each point of the section is proportional to its distance from that edge.

The theory now generally adopted consists in supposing the extensions and compressions to continue up to the point of rupture proportional to the strains, as is actually the case up to the limit of elasticity, and therefore, that the beam turns round a neutral axis, passing through the center of gravity of the cross section, the force given out by each point being proportional to its distance from the neutral axis. This last theory is found to give the best results in the case of timber and wrought iron, especially wrought iron arranged in the forms usual in girders. The second represents nearly the method of failure of stone, and the first that of cast iron.

Though none of these theories give accurate results, they yet give us means of determining, from particular experiments, the strength of any other beam whatever. For example, these theories agree in giving the strength of a rectangular beam to be proportional to the area of cross section multiplied by the depth, and inversely proportional to the length of the beam, since the strain increases directly as the length. This, when expressed mathematically, is

$$W = C\frac{bd^2}{l} \qquad (I.)$$

Where w = breaking weight in tons.
b = breadth of beam in inches.
d = depth of beam in inches.
l = length of beam in inches.
C = a constant number for beams of the same material, to be determined by experiment.

This result is borne out by experiment—that is to say, the constant C being determined by experiment on one beam, the strength of any other is found by multiplying its breadth by the square of its depth and by the constant C, and then dividing by its length. In the case of a beam supported at each end and loaded by a weight in the middle, as in fig. 2, the strength is also given by the formula,

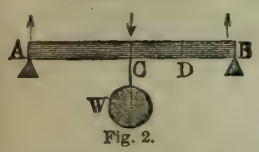

Fig. 2.

$$W = c\frac{bd^2}{l} \qquad (II.);$$

but c, in this case, is 4 times the value of C in the formula for a beam loaded at one end. The truth of this may be seen from the consideration that the beam ACB, fig. 2, may be treated as if it were two beams, each fixed at the point C at one end, and pressed upwards by the reaction of the supports at A and B, their other ends. This reaction is evidently equal to $\frac{W}{2}$; so that the breaking weight of the whole beam ACB, supported at both ends, resolves itself into that of the beam CB or AC of length $\frac{l}{2}$, acted on by the weight at one end $\frac{W}{2}$; this by formula (I.) is,

$$\frac{W}{2} = C\frac{bd^2}{\frac{l}{2}}$$

$$\text{or, } W = 4C\frac{bd^2}{l} = c\frac{bd^2}{l};$$

$$\text{therefore, } c = 4C \text{ or } C = \tfrac{1}{4}c.$$

Experiments on the transverse strength of beams are generally made in the manner of fig. 2. The following table, from experiments by Mr. Barlow, gives the value of c for beams supported at each end and loaded in the middle:

	Tons.
Cast iron	13½
Wrought iron	12
English oak	2½
Red pine	2⅘

These numbers when substituted in the formula give the breaking weight, ¼d of this will be the safe load in practice. The transverse strength of cast iron is considered so good a test of its value, that in specifications of iron-work, it is generally required to be of such a quality that a bar of it, of certain dimensions, will bear a specified weight at the center; for example, 'that a bar of it, 42 inches long, 2 inches deep, and 1 inch wide, set on bearings 36 inches apart, shall bear, without breaking, 30 cwt. suspended in the middle.' If a beam be loaded uniformly over its length, as in fig. 3, it will bear twice as much as if the load be condensed at the center, as in fig. 2. Also, if the load be placed some distance from the center, as at D, fig. 2, the load it will bear is to the load borne at the center, C, inversely as the rectangle of the segments into which the beam is divided by the point of application of the load are to one another, that is, as AC × CB or $\frac{l^2}{4}$ is to AD × DB, from which it follows that it will bear less weight at the center than at any other point.

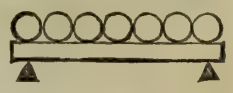

Fig. 3.

Since the strength of a rectangular beam is proportional to the square of the depth, multiplied by the breadth, it is evident that by increasing the depth and diminishing the breadth we shall, up to a certain limit, increase the strength of a beam without increasing its weight; for example, let A and B, fig. 4, be the sections of two beams, of which A is 2 inches broad and 2 deep, and

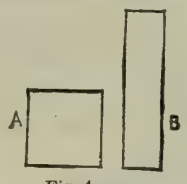

Fig. 4.

Fig. 5.

B 4 inches deep and 1 inch broad, they are of the same sectional area—viz., 4 square inches, but the strength of B is to the strength of A as $4^2 \times 1$ is to $2^2 \times 2$, or as 16 to 8, that is, 2 to 1, that is to say, B is twice the strength of A. Hence arises the advantage of the double T forms so generally used in iron girders, fig. 5, the strength of which forms are proportional to the area of the top or bottom plates multiplied by the depth. For a beam of the form in fig. 5, loaded as in fig. 2, the following formula will give the breaking weight:

$$W = C\frac{ad}{l}$$

Where a = the area of the top or bottom flange in square inches.
C = 4 times the destroying load per square inch of the material, under direct tension or compression in tons.
d = depth of the beam in feet.
l = length between supports in feet.
W = breaking weight at the center in tons.

For cast-iron beams, when the area of the bottom flange is made 6 times that of the top, which has been found by experiment to be the best arrangement, and the strength is measured by the tensional strain, supported by the bottom flange, that is, 6½ tons per square inch,

$$C = 6\tfrac{1}{2} \times 4 = 26 \text{ tons.}$$

For wrought-iron beams,

$$C = 4 \times 20 = 80 \text{ tons for the lower flange}$$
$$\text{and } C = 4 \times 16 = 64 \text{ tons for the upper flange.}$$

Another way of throwing the great body of the material at a distance from the neutral axis is, to make it into the shape of a tube or hollow cylinder. Let B be the section of a hollow cylinder, the thickness of whose walls is represented by the shaded ring; and A be the section of a solid cylinder of the same material. If the area of A is equal to that of the ring in B, the two cylinders will contain the same quantity of matter, but B. will be stronger than A, nearly in proportion as cg is longer than dg.

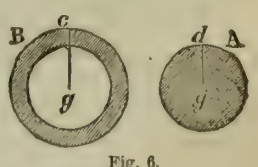

Fig. 6.

The principle of hollow structure prevails both in nature and art, wherever strength and lightness have to be combined. It is seen in the stems of plants, especially of the grasses; the bones of animals are also hollow, and those of birds, where great lightness is required, are most so. A feather, with its hollow stem, is perhaps the best instance of the union of strength and lightness that could be given. In art, again, we have hollow metal pillars; and sheet-iron for roofing and other purposes is *corrugated*, or bent into ridges and furrows, to give it depth. Each ridge or furrow is, as it were, half a tube, and resists bending with twice or thrice the energy it would if flat.

The most striking application of the principle of hollow structure is seen in tubular bridges. Fig. 7 represents a section of the tube of the Conway Bridge. The object being to resist a vertical strain, the form is made rectangular, and the chief mass of the material is thrown into the top and bottom. The tube may, in fact, be considered as an immense beam or girder constructed on the principle of fig. 5, the top and bottom being the two flanges, and the two sides serving to connect them, instead of the one rib in the middle. As it is constructed of plate-iron, the top requires more metal than the bottom, in order to resist the compression; but instead of putting the metal into one thick plate, or into several plates laid the one on the other, it is made to form a set of minor tubes or cells, which give additional stiffness and strength to the whole tube. The floor, in like manner, contains cells. Each of the tubes over the Conway is 24 feet high, 14 feet wide (outside), and 420 feet long, and weighs 1300 tons; yet these enormous hollow beams sustain not only their own weight, but the heaviest railway-trains without sensible deflection.

Fig. 7.

Fig. 8 represents an ingenious contrivance for strengthening the wooden beams supporting a bridge. An iron rod, fixed to the beam AB at the two ends, is kept at a distance by struts *c*, *c'*. The beam cannot now be bent downwards without stretching the rod; which thus has to bear the tensive strain, while the beam itself sustains only the compressive strain.

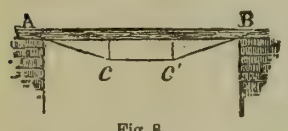

Fig. 8.

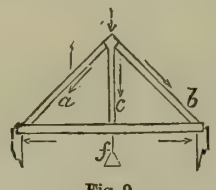

Fig. 9.

Another way of removing part of the strain from a girder, is to fix a king-post, *c*, and two oblique pieces on its upper side, as in fig. 9. The whole is now one composite girder; and when any weight, *f*, bears upon it, the whole of the compressive strain is thrown upon the pieces *a*, *b*, and only the tensive strain is left for the beam to sustain.

When a beam AB is fixed at one end, and loaded at the other, the strain is greatest at B, and is less at other points, as *c*, *c'*, in proportion as Ac, Ac', the levers at which it acts, are less than AB. The beam may therefore be made to taper off towards the end, and we may determine the exact form the beam should have, in order to be equally strong at every point. For supposing the breadth uniform, the strength increases as the squares of the depths *c'd'*, *cd*, while the strain increases as the levers Ac' Ac; and thus, if Ac: Ac' : : cd^2 to $c'd'^2$, the strengths are equal at those points. This proportion will always hold good, if the curve of the beam is that of a parabola; and, accordingly, this is the shape given to the beams of steam engines.

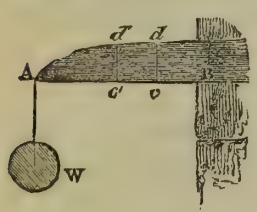

Fig. 10.

In beams supported at both ends, the strain is greatest in the middle; girders are therefore made strongest in the middle, and taper towards the ends.

4. *Shearing Strain.*—This force is called into play when a plate is cut by shears, or when a riveted or bolted joint is torn asunder, in which case the rivets are sheared across. The effect of it is to cause the particles in one plane to slide over those in another; this is resisted by their mutual coherence, and the magnitude of the resistance depends on the number of the particles, that is, on the area of cross section of the body sheared. The following laws are the result of experiment—1. The ultimate resistance to shearing is proportional to the area of section of the bar sheared. 2. The ultimate resistance of any bar to a shearing strain is nearly the same as the ultimate resistance of the same bar to a direct longitudinal strain.

5. *Torsion.*—If one end of the axle or shaft of a wheel is immovably fixed, and a power acts at the circumference of the wheel (or at the end of a lever or winch), the power may be so increased as to twist the shaft asunder at its weakest point. If a shaft A has twice the diameter of another shaft B, there will be four times as many fibers in the section of fracture of A, to resist the twist, as in that of B. But as the separation takes place by the one end of the fracture turning round upon the axis of the shaft, making the ends of the separating fibers describe circles, those fibers that are furthest from the center will have the greatest power of resistance, and the sum of their moments, or their united effect, will be in proportion to their mean distance from the center. This mean distance in A is twice that in B; therefore, the resistance in A is 2×4, or 8 times the resistance in B. Generally, *the strength of shafts to resist torsion is as the cubes of their diameters.* The torsive strengths of shafts 1 inch diameter, and with weights acting at 1 foot leverage, being found by experiment for different materials; the strength of shafts of other dimensions is found from these 'constants' by multiplying by the cube of the diameter, and dividing by the length of the lever. It is evident that the torsive strength of a hollow shaft will be greater than that of a solid one of the same quantity of material, on the same principle that its transverse strength is greater. The rule used by Boulton and Watt for calculating the diameters of their wrought-iron shafts was as follows:

$$\text{Diameter of shaft in inch.} = \sqrt[3]{\frac{120 \times \text{horse-power}}{\text{Revolu. per minute.}}}$$

This is found to make the shafts rather too light; and the following variation gives safer practical results:

$$\text{Diameter of shaft in inch.} = \sqrt[3]{\frac{240 \times \text{horse-power.}}{\text{Revolu. per minute.}}}$$

STREPSI'PTERA (Gr. twisted-wings), an order of insects called RHIPIPTERA (Gr. fan-winged) by Latreille, but first established by Kirby. The first-known species were observed by Rossi, and referred by him to the order *Hymenoptera*. The order S. consists of a small number of species, very singular in structure and habits, apparently forming a connecting link between *Coleoptera* and *Hymenoptera*. The species are all small, and in their larval state, live parasitically in the bodies of bees and wasps. Their natural history has been the subject of much attention since they were discovered; but much still remains obscure. The species form the two genera, *Stylops* and *Xenos*.

STRE'TCHING-COURSE, in Masonry or Brick-work, is a course in which the stones or bricks are placed with their longest sides along the face of the wall. The stones are called *stretchers*, as those placed at right angles to them with their end exposed are called *headers*.

STRE'TTO (Ital. bound), in Music, a term which signifies that the movement to which it is prefixed is to be performed with rapidity gradually accelerating towards the close.—The term *stretto* is also applied to the recurrence in a fugue of the subject in one part before it has come to a close in another. See FUGUE.

STRI'Æ, the fillets between the flutes of columns, pilasters, &c.

STRICKLAND, AGNES, an English authoress, the daughter of Thomas Strickland, Esq., was born at her father's seat, Reydon Hall, near Southwold, in Suffolk, in the year 1806. She was the third daughter of a family of six daughters and two sons, nearly all of whom have contributed something to the literature of our time. Her first compositions were mostly in the poetical vein, and consisted of anonymous contributions to periodicals. About the year 1825, however, she published in conjunction with her sister Susanna (afterwards Mrs. Moodie), a volume of *Patriotic Songs;* which was followed, in 1826, by a little volume bearing her own name exclusively, and entitled *Worcester Field, or the Cavalier; a Poem, in Four Cantos, with Historical Notes*, which was favorably received by some of the reviews. *Worcester Field* was followed by *The Seven Ages of Woman, and other Poems* (Lond. 1827); and this by *Demetrius, a Tale of Greece, in Three Cantos* (Lond. 1833), written in the meter of Byron's *Corsair*. In 1836, she published a little volume entitled *Floral Sketches, Fables, and other Poems;* republished in 1861. With this the list of Miss A. S.'s poetical works ends.

Among her prose works are: *The Rival Crusoes*, published without date; *The Pilgrims of Walsingham, or Tales of the Middle Ages, an Historical Romance* (2 vols., 1835); *Tales and Stories from History* (1836); *Alda, the British Captive* (1841); *Historical Tales of Illustrious British Children* (1847; new ed. 1858); *Historic Scenes and Poetic Fancies* (1850); *Old Friends and New Acquaintances* (2 series, 1860—1861). All these, however, are but of small import in comparison with her well-known work, *Lives of the Queens of England from the Norman Conquest, with Anecdotes of their Courts*, in 12 vols. (Lond. 1840—1848; new ed., 8 vols., 1851—1852). In this work, the materials for which she discovered by diligently ransacking among the treasures of the British Museum and other great public repositories of historic documents, Miss S. was largely assisted by her sister Elizabeth, an assistance which she gratefully acknowledges in her Preface. It was dedicated to Queen Victoria; and as each volume successively appeared, its picturesque style and anecdotical character made it a general favorite, especially among that class of readers whose object in reading history is rather amusement than philosophical instruction. At the same time, it must be owned that in these *Lives* she has added materially to our stock of historical information. Miss S.'s *Lives of the*

Queens of England, concluding with the biography of Queen Anne, have been followed by the *Lives of the Queens of Scotland, and English Princesses connected with the Regal Succession of Great Britain*, in 8 vols. (Edin. and Lond. 1850—1859); and these by her *Lives of the Bachelor Kings of England* (Lond. 1861), containing the lives of William Rufus, Edward V., and Edward VI. Miss S. published a novel entitled *How will it end?* (1865); *Lives of the Seven Bishops* (1866). In 1871 she received a pension of £100 She died in July 1874.

STRI'CTURE is a term employed in Surgery to denote an unnatural contraction, either congenital or acquired, of a mucous canal, such as the urethra, œsophagus, or intestine. When, however, the affected part is not mentioned, and a person is stated to suffer from stricture, it is always the urethral canal that is referred to. Contraction of this canal may be either permanent or transitory; the former is due to a thickening of the walls of the urethra, in consequence of organic deposit, and is hence termed organic stricture; while the latter may be due either to local inflammation or congestion, or to abnormal muscular action: the first of these varieties may be termed inflammatory or congestive stricture; and the second, spasmodic stricture. The last-named form seldom exists except as a complication of the other kinds of stricture. There are two principal causes of organic stricture—the first being inflammation of the canal, and the second injury by violence. Inflammation is by far the most common cause, and gonorrhœa is the common agent by which it is excited. Not unfrequently, stimulating injections thrown into the urethra, with the view of checking the gonorrhœal discharge, excite an inflammatory action, which gives rise to stricture. Fortunately, it is only in exceptional cases that a stricture results from inflammation of the urethra, the inflammation, in the great majority of cases, terminating by resolution, and leaving the canal as healthy as before the attack. It is when the complaint assumes a chronic character that it most commonly lays the foundation of stricture. Stricture from the second cause arises from such cases as falling across spars, scaffolding, ladders, &c., or on some sharp object which punctures the perinæum, as from earthenware vessels which break under the sitter.

The earlier symptoms of stricture are a slight urethral discharge and pain in the canal, behind the seat of the stricture, at the time of micturition. The stream of urine does not pass in its ordinary form, but is flattened or twisted; and as the disease advances, it becomes smaller, and ultimately the fluid may only be discharged in drops. The straining efforts to discharge the urine often induce Tenesmus (q. v.).

As the case advances, the urine becomes alkaline and ropy, and deposits a precipitate when allowed to stand; and attacks of complete Retention (q. v.) occur with increasing frequency. But these symptoms are not in themselves sufficient to establish the presence of stricture. It is necessary to examine the urethral canal with a Catheter (q. v.) or Bougie (q. v.), to ascertain whether an organic obstruction exists, whether one or more strictures are present (as many as eight have been recorded, although four are rare; and one is the most common number), and their caliber. The treatment of organic stricture is too purely surgical to be discussed in these pages: it is sufficient to state that its object is twofold, viz, first, to restore the natural caliber of the canal, so far as this can be safely effected; and secondly, to maintain this patency, after it has been established.

Spasmodic stricture may occur from any of the following causes: the presence of organic stricture or of inflammation of the mucous membrane; from an acrid condition of the urine; from the administration of cantharides, turpentine, &c.; and from the voluntary retention of urine for too long a time. The treatment consists in the removal of the causes as far as possible, and the hot bath. The inhalation of chloroform sometimes gives immediate relief; and several cases are recorded in which, when the spasm occurred periodically, it was cured by quinine. Inflammatory or congestive stricture commonly arises when a recent purulent discharge from the urethra has been checked by external cold or wet. The patient complains of heat, fulness, and soreness in the perinæum; the passage of the urine is extremely painful, the stream being small, and ceasing before the bladder empties. The treatment is much the same as that for Retention of Urine (q. v.).

STRI'GAU or STRIEGAU, a town of Prussia, province of Silesia, and government of Breslau, is situated on Strigau Water, 32 miles west-south-west of Breslau. It has manufactures of woolens and linens. Pop. (1880) 11,470.

STRIKE, a term borrowed by geologists, from the German *streichen*, to extend, and adopted with the technical meaning it has in that language. It is applied to the direction of the outcrop of a stratum—the line which it makes when it appears on the surface of the earth. This line is always at right angles to the dip of the bed. The angle of dip and the direction of strike are determined by a clinometer and compass. A perfectly horizontal stratum can have neither dip nor strike.

STRIKES. See COMBINATION.

STRING-COURSE, a thin projecting course of stone or brickwork in a wall, generally ornamented with a moulding, and made to go round windows or other openings in the wall.

STRINGE'NDO, a term used in Music to denote a gradual acceleration in the time.

STRI'NGHALT is a peculiar catching up of the horse's limbs, usually of one or both hind limbs. It is most noticeable when the animal is first brought out of the stable, when he is excited, or made to turn suddenly round; it is a variety of chorea or St. Vitus's dance. Although a serious eyesore, it does not interfere with usefulness, and is quite incurable.

STRO'BILA. See TAPE-WORMS.

STRO'MBIDÆ, a family of gasteropodous molluscs, of the order *Pectinibranchiata*, nearly allied to *Buccinidæ* (Whelks, &c.) and *Muricidæ*. The shell has a canal, the external lip of which, as it attains maturity, becomes more or less dilated, and is marked with a sinus, whence the head issues when the animal comes out. The foot is narrow and small, but is employed in active leaping movements, during which the shell oscillates from side to side. The species are numerous, and are mostly inhabitants of tropical seas. Some of them are among the largest of molluscs. *Strombus gigas* is the largest known univalve. It is found in the West Indies, on

Fountain-shell (*Strombus gigas*).

reefs in shallow water, and is fished both for the table and on account of the shell. Great numbers of the shells are imported into Britain; 300,000 have been brought to Liverpool in a year. They are sometimes called Fountain-shell, from their occasional use as a garden ornament. Their chief use, however, is by cameo-makers, by whom they are valued for their solid and delicately tinted substance. A shell sometimes weighs four or five pounds. Pearls of a delicate pink color are sometimes found in this shell. The *Strombi* are sometimes called wing-shells, from the dilated margin of the lip.

STRO'MBOLI, one of the group of the Lipari Islands (q. v.), the most north-easterly of the group, is about 12 miles in circumference, circular in shape, and contains 2000 inhabitants. It is wholly of volcanic formation, and rises to the height of 3100 feet above sea-level. On its western side is a volcano of considerable activity. Sulphur and pumice-stone are gathered in large quantities, and among the chief agricultural products are cotton, wine, and excellent fruits.

STRO'MNESS. See ORKNEY ISLANDS.

STONGY'LIDÆ, a family of nematode worms, possessing the following common characters. The body is round, and sometimes very much elongated, and almost thread-like. The mouth is round, oval, or triangular, and situated at the extreme anterior end of the body. The tail of the male is commonly furnished with a bursa, usually emitting two spicules. The whole family is parasitic and contains a number of genera. Some of the S. are parasitic in man, some in mammals, birds, reptiles, &c.

STRO'NGYLUS (from the similar Greek word signifying *round*) is the term applied to a genus of the family *Strongylidæ* (q. v.) of nematode parasitic worms. The only true S. infesting man is the *S. bronchialis* of Cobbold, previously known as *Filaria hominis bronchialis*, *Hamularia compressa*, &c. The male usually measures rather more than half an inch, while the female is upwards of an inch in length. For the general and specific characters of this rare entozoon, the reader is referred to Cobbold's *Entozoa*, p. 357. The worm was originally discovered by Treutler in 1790, who found several individuals in the bronchial glands of an emaciated subject. In 1845 it was again found by Dr. Fortsitz at Klausenberg in Transylvania, in the lungs of a boy six years old. These are the only two cases recorded by Küchenmeister and Cobbold of its occurring in the human subject; but closely-allied species, *S. paradoxus* and *S. micrurus*, are occasionally found according to Cobbold, in the lungs and air-passages of the pig and the calf respectively, and Küchenmeister states that he has found a species in the lungs of the sheep.

Closely allied to S. is the genus *Eustrongylus* of Diesing and Cobbold, which contains the species *E. gigas*, more commonly known as the *Strongylus gigas* of Rudolphe, Cuvier, and others. This is the largest nematode worm at present known to infest man or any other animal; 'the male measuring from ten inches to a foot in length, and ¼th of an inch in breadth; whilst the female is said to attain a length of over three feet, its transverse diameter being fully half an inch; body cylindrical, and more or less tinged with redness; head obtuse, and furnished with a simple oval aperture surrounded by six chitinous nodules: mode of reproduction, probably viviparous; eggs broadly oval, measuring about $\frac{1}{350}$″ from pole to pole.'—*Op. cit.*, p. 358. This worm occurs, according to Bremser, in the kidneys and bladder, sometimes

Strongylus gigas.—From Cobbold's *Entozoa*.

in the abdominal cavity and the omentum, more rarely in the lungs and liver of 'martens, dogs, wolves, seals, otters, oxen, and horses.' Fortunately, it is very rare in man, and, according to Cobbold, weasels are the animals in which it is most commonly found. The accompanying figure shows one of these worms coiled up within the pelvic cavity of the kidney of the coati, a species of monkey. The symptoms to which it must give rise must be much the same as those arising from abscess and degeneration of one of the kidneys, or from renal calculi. The diagnosis in a suspected case could only be established by the detection of the eggs or embryos in the urine.

STRO'NSAY, one of the Orkney Islands, lies 15 miles north-east from the town of Kirkwall. It is 7¾ miles long, and 6 miles in extreme breadth. Pop. (1871) 1267; (1881) 1274.

STRONTIA. See STRONTIUM.

STRO'NTIUM (symb. Sr, equiv. 43·8—new system, 87·6—sp. gr. 2·54) is a ductile and malleable metal, somewhat harder than lead, and of a pale yellow color. When heated in the air, it burns with a crimson flame, and becomes converted into its oxide, strontia. It is unaffected by the action of dry air, but it decomposes water at an ordinary temperature, hydrogen being explosively developed; and it burns in chlorine gas, and in the vapor of iodine, bromine, and sulphur. It dissolves in dilute nitric acid, but the strong acid has scarcely any effect on it. This metal does not occur in the native state, but exists as a carbonate in the mineral *Strontianite* (so called from its being first found near Strontian, in Argyleshire), and as a sulphate in the mineral known as *Celestine* (so called from its delicate blue tint). It is obtained by the voltaic decomposition of the chloride of strontium. This metal bears to barium the same close relation that sodium bears to potassium; and the compounds of S. resemble those of barium not only in their composition but in their properties.

The oxide of S., commonly known as STRONTIA, is obtained in the same way, and resembles in almost all respects the corresponding oxide of barium, except that it is inert when taken into the system, while baryta is poisonous. When a small quantity of water is poured upon it, it slakes, giving out heat.

The salts of strontia resemble those of baryta in their general characters, and in their being precipitated from their solutions by sulphuric acid and the soluble sulphates; but they differ from them in not being thrown down by silico-fluoric acid or hyposulphite of soda, and in their communicating to the flame of the spirit-lamp and to burning substances generally, a brilliant purple-red color. The salts of strontia occur only in the mineral kingdom, and are never found as normal ingredients of organic bodies. *Carbonate of Strontia* (SrO,CO_2) occurs native both in a massive and crystalline form, and may be obtained artificially as a white powder by precipitating a soluble salt of S. with carbonate of soda. *Sulphate of Strontia* occurs native in *Celestine*, a mineral which is found in beautiful rhombic prisms in Sicily. *Nitrate of Strontia* (SrO,NO_5) separates from a hot concentrated solution in large colorless transparent anhydrous octahedral crystals, which dissolve freely in water. By the addition of nitric acid, it is precipitated from its aqueous solution. This salt is insoluble in alcohol; but when finely powdered, and mixed with it, it communicates to the alcoholic flame a beautiful red or crimson color. In consequence of this property, it is employed by the makers of fireworks. A mixture of 40 parts of nitrate of strontia with 10 of chlorate of potash, 13 of sulphur, and 4 of sulphide of antimony, deflagrates with a magnificent red color, and constitutes what is popularly known as *Red Bengal Fire;* but the mixture is dangerous both to prepare and to preserve, having more than once been the occasion of frightful accidents to the manufacturers from its becoming ignited spontaneously.

The most important of the haloid salts of S. is the *Chloride* (SrCl), which may be obtained in crystals containing six equivalents of water. The water is expelled at a moderate heat, leaving the chloride anhydrous. The chloride is the only salt from which the metal has hitherto been obtained.

Regarding the history of this metal, it may be observed that strontia was discovered as an independent substance almost simultaneously by Hope and Klaproth in 1793. In 1807, Davy obtained barium and strontium from their oxides, but not in a pure state; and it was not till 1855 that Bunsen and Matthiessen succeeded in procuring perfectly pure specimens of the metal.

STRO'PHULUS. See RED GUM.

STROUD, a parliamentary borough and market-town of Gloucestershire, nine miles south-south-east of the city of Gloucester, stands in a beautiful and extensive valley, at the confluence of the Frome and Slade, which unite to form the Stroudwater or Frome. It is the center of the woollen manufactures of Gloucestershire, and contains a number of woollen and silk mills. The water of the Frome is peculiarly adapted for use in dyeing scarlet and other grain colors; and on this account, cloth-factories and dyeworks have been built along its banks for the distance of 20 miles. The borough of S. forms part of the great west of England cloth districts. Pop. of parliamentary borough, which sends two members to the House of Commons (1871), 38,610; (1881) 45,703.

STRUENSEE, JOHANN FRIEDRICH, COUNT OF, a man who, in last century, attracted the attention and excited the sympathy of the whole of Europe, by his elevation and downfall at the Danish court. S. was born 5th August 1737, at Halle on the Salle, where his father, Adam Struensee, the author of the old Halle Hymn-book, was pastor of the Ulrichskirche. Young S. studied medicine, and when scarcely 19 years old passed as Doctor. Early alienated from positive Christianity, he zealously embraced the philosophy which had then arisen in France, and became a disciple of Helvetius and Voltaire. When his father removed to Altona, he accompanied him, and was soon afterwards appointed traveling physician to the young king, Christian VII. of Denmark; and on their return from a tour, physician in ordinary. At first, the young queen, Caroline Matilda, sister of George III. of England, looked upon him with mistrust; and it was not till 1770, when S. successfully managed the inoculation of the two-year old crown-prince, afterwards King Frederick VI., that she came round to him, intrusted him with the education of the prince, and by degrees made him the confidant of her unhappy position. S. removed the estrangement between the royal pair, which was the work of the favorite Holck, and, in consequence, rose still higher in favor with both. He was appointed Reader to the king, and Private Secretary to the queen. Since the revolution of 1660, Denmark had been under the domination of the nobility, who, as a council of state, governed the country. S. saw the disadvantages of this government of the nobles, and formed the ambitious resolve to come forward in this land of his adoption as an enlightened reformer after the model of Frederick II. To begin with, he effected the downfall of the favorite Holck, in whose stead his friend Brandt was appointed Royal Companion and Director of the Court Amusements. In order to gain the love of the people, S. proclaimed the freedom of the press. The council was dissolved, and a proclamation issued to the effect that the royal power in all its purity, as it had been handed down from olden times, was to be re-established. These measures amounted in reality to a revolution, and to a declaration of war against the aristocracy.

The queen and S., in whose hands the whole power now was, chose new ministers, and excluded the feeble Christian entirely from the management of affairs. In July 1771, S. received the title of Cabinet Minister, along with unlimited power. He brought several men from Germany, whom he appointed to different offices. This introduction of strangers caused great dissatisfaction among the people. In opposition to the politics of his predecessors, S. endeavored to free Denmark from Russian in-

fluence, and to find a natural ally in Sweden. The changes which he undertook in the internal affairs were directed to the advancement of the prosperity of the country, of civil liberty, and enlightenment. He put the finances in order, reduced the expenditure, loosened the fetters in which industry and trade had been bound, encouraged education, mitigated the penal laws, and brought order into the administration. An act passed in 1771, to a certain extent abolished serfage. All these reforms, which are in operation in the Danish dominions at the present day, were excellent; but the haste and want of statesmanlike skill with which they were carried out, made them appear as the acts of the most vexatious tyranny. S. committed a great mistake, too, in recklessly obtruding his philosophy of enlightenment in the face of the strict orthodox clergy and the pious prejudices of the people.

S. had scarcely been in power a year when the symptoms of reaction appeared in all quarters. The queen gave birth to a daughter in 1771, which, in the condition of the king, gave rise to most scandalous reports. The British ambassador, Lord Keith, who saw the catastrophe approaching, proposed to S., by the advice of George III., to take refuge in England; but S. declined doing so. At the head of the hostile party was Christian VII.'s stepmother, Juliana Maria, Princess of Braunschweig-Wolfenbüttel, who was impatient of the domination of the queen and Struensee. A bold stroke was to precipitate S. and ruin the queen, and the night when a court ball was to take place was fixed upon for carrying out the plot. The conspirators assembled at the king's stepmother's, and by a secret door entered the bedroom of the king, and obliged him to make out 15 warrants of arrest, among others for Struensee. Christain was prevailed upon, but with much difficulty, to write out orders to arrest and convey his consort the queen to Kronenburg. S. and the queen were then taken prisoners, and the former was treated with extreme harshness, put in chains, and brought to the citadel. He was accused of an assault on the person of the king; of the intention to compel Christian to abdicate the throne; of criminal intercourse with the queen; of using a fatal system in the education of the crown-prince; and of the usurpation and abuse of supreme power. Not one of these points could be legally proved. In a second examination, however, S., with tears, confessed to having had improper intercourse with the queen; but some of his contemporaries affirm that he made the confession under threat of torture. On this important confession, a second commission was sent to the queen at Kronenburg, from whom, however, not the slightest confession of guilt could be extorted.

When one of the commissioners at last remarked that if she made S. guilty of falsehood, he would be put to a disgraceful death for slandering majesty, the queen seized a pen, and began to sign a paper which contained the confession of her guilt. She had not finished when she sunk in a swoon in her chair; and it is said that some one put the pen in her hand, and guiding it, finished the name, 'Caroline Matilda.' S. was found guilty of a great and capital crime, and was sentenced to a cruel death. It was wished by some to proceed further against the queen; but the commissioners were satisfied by the simple separation of the royal pair, especially as the British ambassador threatened the appearance of a British fleet. After the king had confirmed the sentence, not without being urged by the Russian ambassador, it was carried into execution on the 28th April 1772, amid the rejoicings of the multitude. In the prospect of death, S. is said to have returned to the Christian faith. There is no doubt that he did not deserve his fate, but that he fell a sacrifice to the party of the nobles. The execution of his friend Brandt, which took place at the same time, was a still clearer case of legal murder, as he never took any part in the affairs of government. S.'s brother would have shared the same fate, had not Frederick II. claimed him in a menacing manner as a Prussian subject. Queen Caroline Matilda left Denmark in May 1772, and died of grief in 1775, in the castle of Celle in Hanover.

See works on S. by Höst, Falkenskjöld, Münter, Jenssen-Tusch (1864), and Schiern (1871); and the tragedies by Beer and Laube.

STRUGGLE FOR EXISTENCE. See DARWINIAN THEORY.

STRUTS, straining pieces of timber in a roof, used to strengthen the principal Trusses (q. v.).

STRUVE, FRIEDRICH-GEORG-WILHELM, a celebrated astronomer, was born at Altona, April 15, 1793, educated at the university of Dorpat (Russia), and appointed to a post in the observatory of that place in 1813. He became Director of the Dorpat Observatory in 1817, and continued with the utmost assiduity his observations and researches respecting double and multiple stars, adding immensely to our knowledge of these systems, and earning for himself the reputation of being one of the most skilful of practical astronomers. The instrument with which he observed was a Fraunhofer's (q. v.) refractor, of 10 inches aperture, and 13½ feet focal length; and with this telescope, in gleaning from the depths of space the materials for his three important works on double stars (1822 and 1828, 1837 and 1840, 1852), he examined no fewer than 120,000 of these twinkling luminaries. His investigations have led him to the conclusion, that the number of true double stars is much larger than was previously supposed (see STARS). S. also executed a number of important geodetic operations, such as the triangulation of Livonia, in 1816—1819, and the measurement of an arc of the meridian in the Baltic Provinces, in 1822—1827; which was subsequently (1828—1856) extended by him, in conjunction with Hansteen (q. v.) and Selander, to the North Cape; and by General Tenner southwards to Ismail in Turkey. This latter undertaking, the most extensive trigonometrical operation ever performed, when completed, gave the length of a meridian arc of 20°, and enabled geometers to determine with increased accuracy the exact form of the earth. Meanwhile, S. had been appointed, in 1839, director of the best organized observatory in the world, that of Pulkova (q. v.), and also chosen *correspondant* in the astronomical section of the Academy of Sciences of Paris. He died at St. Petersburg, 23d November 1864.—His son, OTTO-WILHELM STRUVE, also an eminent astronomer, was born at Dorpat, May 7, 1819, was educated under his father's direction, became his chief assistant at Pulkova, and the Director of the observatory after his death. He has made numerous astronomical discoveries, among which are more than 500 new double stars, and (1847) a satellite of Uranus, and has written numerous important papers, the most noticeable of which set forth his researches on the inner or dusky ring and on the variation in breadth of the bright rings of Saturn, and on the periodic motions of double stars.

STRY'CHNIA, or STRY'CHNINE. See NUX VOMICA.

STRY'CHNOS, a genus of trees of the natural order *Loganiaceæ*, having a five-lobed calyx, a tubular funnel-shaped or salver-shaped corolla, with a five-partite limb, five stamens, a filiform style, numerous ovules, and a one-celled berry, with a leathery rind, many-seeded, or, by abortion, one-seeded, the seeds discoidal and compressed. To this genus belongs the *S. nux vomica*, a tree of middling size, with ovate stalked leaves, a native of India, the fruit of which is produced in great abundance, and is about the size of a small orange; the seeds are the *Nux Vomica* of commerce, and yield *Strychnine*. The bark partakes of the poisonous quality of the seeds. The wood of the tree is very hard and durable. The Clearing-nut (q. v.) and St. Ignatius' (q. v.) Bean are produced by species of this genus, to which also belongs the tree (*S. toxifera*) which produces the Woorali or Curare (q. v.) poison of South America. Another species is the UPAS TIEUTÉ (*S. Tieute*) of Java, a large climbing shrub, the bark of which is etxremely poisonous, containing a very large quantity of strychnine. The wood of a species found in the north of India (*S. colubrina*), which is also a climber, is an imaginary cure for snake-bites. The bark of *S. pseudo-quina*, a Brazilian species, is used as a substitute for cinchona.

STRYPE, REV. JOHN, a voluminous ecclesiastical historian, was born in London in 1643. He studied at Cambridge, entered the church, and held for many years, with other smaller livings, the rectory of Low Leyton, in Essex. He died at Hackney in 1737, having reached the great age of 94. His works fill thirteen large folio volumes. The most important are—*Memorials of Archbishop Cranmer* (1694); *Life of Sir Thomas Smith, Secretary of State to Edward VI. and Elizabeth* (1698); Lives of *Bishop Aylmer* (1701), *Sir John Cheke* (1705), *Archbishop Grindal* (1710), *Archbishop Parker* (1711), and *Archbishop Whitgift* (1718); *Annals of the Reformation* (vol. i. 1709, vol. ii. 1723, vol. iii. 1728, and vol. iv. 1731); *Ecclesiastical Memorials*, relating to religion and the Church of England under Henry VIII., Edward VI., and Queen Mary, in 3 vols. folio, published in 1721. This is his best work, forming, with Burnet's more readable *History of the Reformation*, a consecutive and full account of the reformed Anglican Church. S. also published an enlarged edition of Stow's *Survey of London*, with several sermons and pamphlets. As a writer, he is heavy, but honest and plodding, and he was a faithful transcriber of the ancient papers he published, which, he says, were all copied with his own hand.

STUART, CHARLES EDWARD LEWIS CASIMIR, often called the younger Pretender, the eldest son of James Francis Edward, Prince of Wales, known as the elder Pretender, or Chevalier St. George (see STEWART, FAMILY OF), and his wife Clementina Sobieski, grand-daughter of the celebrated Polish monarch, John Sobieski. He was born at Rome, on the 31st December 1720, and bore among the Jacobites the title of Prince of Wales. He served under Don Carlos in Spain, and in his youth is described as having been handsome, affable, and engaging in manners. In 1743, 28 years after his father's unsuccessful attempt to regain the crown, a scheme was contrived in France, with the support of the Jacobites in England, by which Charles Edward was to recover the throne of Great Britain for his family. The first contrived project was to land an army in Kent, where were many ad-

herents of the exiled House; and troops to the number of 15,000 were assembled, and transports provided at Boulogne, Dunkirk, and Calais to carry them to England. But the squadron which was to have convoyed the transports fled before the British fleet under Sir John Norris; a storm destroyed the transports, and most of the troops were drowned. Charles, however, only awaited a favorable opportunity to make a fresh attempt. In July 1745, when George II. was in Hanover, and Scotland almost without military, he sailed from Nantes, in company with the Marquis of Tullibardine, and a few other devoted followers, and landed in the bay of Lochnanuagh, whence he proceeded to Kinlochmoidart, where the Highland clans attached to his cause were summoned to rise. Ten days later, Charles's standard was set up at Glenfinnan; and he marched southwards at the head of a large body of hardy mountaineers. Government offered a reward of £30,000 for the apprehension of the Pretender's son, who retaliated by offering a like reward for the apprehension of the Elector of Hanover. At Perth, the insurgents were joined by the Duke of Perth and Lord Strathallan, with a numerous retinue of followers; and on their approach, Edinburgh surrendered without resistance, the castle, which was in possession of the king's troops, still holding out. Charles took up his residence at Holyrood Palace, where he proclaimed his father king of Great Britain, and himself regent.

Meanwhile, Sir John Cope, the commander-in-chief of the king's troops in Scotland, having collected some reinforcements in the north, came from Aberdeen to Dunbar by sea, and encamped at Prestonpans. He was there unexpectedly attacked by the Highlanders, and ignominiously routed, leaving baggage, cannon, and camp equipage on the field. Contrary to the advice of his council, Charles, who could not bear opposition, resolved to advance into England, though his force hardly exceeded 6500 men. Carlisle surrendered at his approach, and he proceeded unmolested as far as Derby. In the meantime, three English armies, each larger than his own, were preparing to meet him. Being unable to raise any recruits in England, he found it necessary to retreat into Scotland, where he hoped to meet a reinforcement under Lord John Drummond. On their way north, the Highlanders were pursued by the Duke of Cumberland, whom they defeated near Penrith. Finding that Edinburgh was now in possession of the king's troops, Charles, joined by Lord John Drummond and Lord Strathallan, made his way to Stirling. That town surrendered to him, and he laid siege to the castle. General Hawley, in endeavoring to raise the siege, was utterly routed by Lord George Murray, at the head of the Macdonalds of Keppoch. But the advance of the Duke of Cumberland obliged the rebels to retreat further north, and for a time they carried on a desultory war with the king's troops in the neighborhood of Inverness. On 16th April 1746, the Duke of Cumberland encountered Charles's army on Culloden Moor, and opened a heavy cannonade on them. The Highlanders at first rushed boldly forwards; but on the advance of the royal infantry, they gave way; the battle soon became a rout, and the fugitives were pursued and slaughtered by the dragoons, who gave no quarter, and spread carnage and desolation over the country. The rebels lost that day at least 1000 men of the bravest and most devoted to the cause. Charles escaped to the Hebrides, hunted by the king's troops; disguised in female attire, he was conveyed to Skye in an open boat by Flora Macdonald, daughter of Macdonald of Milton. For months he wandered in concealment among the mountains of Skye and the mainland, where he had many hairbreadth escapes; and though his secret was known to hundreds of the poorest of the people, no one was tempted by the £30,000 reward to betray him. He eventually escaped to France, and no further attempts were made to reinstate the exiled family.

Charles Edward remained in France till the peace of Aix-la-Chapelle (1748). It was made a condition of that treaty that France should abandon the cause of the Stuarts; and Charles, refusing to quit France voluntarily, was conducted with a guard out of the kingdom, and retired to Rome.

He married, on 17th April 1772, Louisa Maximiliana de Stolberg-Guedern, daughter of Gustavus Adolphus, Prince of Stolberg-Guedern. The union did not prove a happy one, and the princess withdrew herself from him. See ALBANY, COUNTESS OF. In the latter years of his life, the prince was addicted to intoxication. When his claims ceased to be supported by any foreign power, he dropped the title of Prince of Wales, and assumed that of Count of Albany. He died at Rome, 31st January 1788, and was buried at Frascati. There was no issue of his marriage, but he left a natural daughter, on whom he bestowed the title of Duchess of Albany, and to whom he bequeathed considerable property.

Two brothers, generally known as John Sobieski Stuart and Charles Edward Stuart, endeavored, some years ago, to persuade the world that they were legitimate grandsons of Charles Edward. In point of fact, they were sons of Captain Thomas Allen, R.N., and grandsons of Admiral John Carter Allen, who died in 1800. Their story, as set forth, with some slight mystifications, in a work called *Tales of the Century, or Sketches of the Romance of History between the years* 1746 *and* 1846, was to the effect that their father, in place of being Admiral Allen's son, was a son of Prince Charles and the Princess Louisa, whose birth was kept secret, from fear of the Hanoverian family, and who was intrusted to Admiral Allen, and passed off by him for his own son. The life of Charles S. is detailed in *History of the Rebellion*, 1745—46, by R. Chambers.

STUART, GILBERT CHARLES, American painter, was born at Narraganset, Rhode Island, in 1756. In his boyhood, he went to Edinburgh with a Scotch painter named Alexander, with whom he studied his art; but his master dying, he worked his passage home, and began to paint portraits at Newport. In 1778, he made his way to London, where he led for two years a wild Bohemian life; but his talent was recognized by his countryman, Benjamin West, President of the Royal Academy, who took him into his family, and whose full-length portrait he painted for the National Gallery. In 1781, he opened his studio in London, and painted the portraits of his Majesty George III., H.R.H. the Prince of Wales, the Duke of Northumberland, Sir Joshua Reynolds, John Kemble, Colonel Barré, and many other celebrated characters. He also made a professional visit to Dublin, and in Paris painted a portrait of Louis XVI. In 1793, in the fulness of his powers and fame, he returned to America, and painted portraits of Washington, Jefferson, and many of the distinguished men of the period, and commenced a portrait of John Quincy Adams, which at his death was finished by Sully. He died at Boston, July 1828.

STUART, MOSES, American divine and author, was born at Wilton, Connecticut, March 26, 1780, and educated at Yale, where he remained for some time as a tutor. He began the study of law, but abandoned it for theology, was ordained as pastor of a Congregational church at New Haven in 1806; and in 1809, was appointed Professor of Sacred Literature at the Theological School at Andover, a position he filled till 1848. During this period, in addition to his professorial duties, he wrote a *Grammar of the Hebrew Language*, without points; *Letters to the Rev. W. E. Channing; Hebrew Grammar*, with points (based on Gesenius); *Commentaries on the Epistle to the Hebrews*, and *the Epistle to the Romans;* on the Books of Ecclesiates, *Proverbs, Daniel*, and the *Apocalypse; Hebrew Chrestomathy; Essay on the Liquor Traffic; Essay on Christian Baptism; Hints on the Prophecies; Conscience and the Constitution*—manifesting in all acuteness, vigor, and versatility. He died at Andover, Massachusetts, January 4, 1852.

STU'CCO, a composition used for the finer parts of plasterwork, such as cornices, enrichments, &c. Gypsum (q. v.), or Plaster of Paris, is used for this purpose. A coarser kind of stucco is also used for making floors, and for plastering the exterior of buildings.

STUFFING, in Cookery, means force-meat used for filling the bodies of small animals, such as poultry, or for stuffing openings made for the purpose in large joints. It usually consists of breadcrumbs, savory herbs and other seasonings, minced very fine, and made into a paste.

STUHLWEI'SSENBURG (Hung. *székes Fejérvár*, Slav. *Bielihrad* or *Bialigrad*, Lat. *Alba Regalis* or *Alba Regia*), a royal free town of Hungary, and seat of a bishop, lies in a swampy plain in the neighborhood of the marshes of *Sár-Rét*, 16 miles north-east of Lake Balaton. The principal buildings are the splendid cathedral of the Virgin Mary, the church of St. John, and the bishop's palace. It has several Catholic schools, a military academy, and a theater. The inhabitants manufacture cotton cloths, flannels, leather, silk, and knives ('Stuhlweissenburg clasp-knives'), and extract soda from the swamps, which are, moreover, rich in fish, crabs, tortoises and water-fowl. Pop. (1880) 25,612. S. is built on the site of the Roman *Floriana*, and from 1027 to 1527, was the place where the kings of Hungary were crowned and buried, 14 of whom repose here. In later times, it suffered much from the ravages of war, and was for some years in the hands of the Turks.

STUPA. See TOPE.

STURDY, or the GID, affects sheep, and occasionally cattle, and is caused by the presence within the brain of a hydatid, reaching sometimes the size of a hazel-nut, and floating in a watery fluid enclosed in a membranous sac. This hydatid, when given to dogs, is known to produce tape-worms, and conversely itself originates from the ova of the tape-worm ejected on the pastures by dogs, rabbits, or even by sheep themselves. In the state of ova, or in some of its earlier minuter transitional forms, the hydatid embryo is picked up along with the grass, passes into the blood, and is thence laid down in the soft loose textures of the brain. It is most common in low damp pastures, and amongst sheep from six to twenty months old. The animal cannot properly seek its food, loses condition, staggers when moved, turns stupidly around almost in one spot, and usually towards the side on which the hydatid lies. The parasite and its sac may generally be safely removed by placing the sheep, with its feet tied,

on a table or bench, searching for the softened portion of the skull, which generally overlies the hydatid, laying back a flap of skin, and introducing the trochar and canula, and when the sac is deep-seated, cautiously withdrawing it with the help of a small syringe. Protected by a leather cap and simple water dressings, the wound speedily heals.

STU'RGEON (*Accipenser*), a Linnæan genus of cartilaginous fishes, now forming the family *Sturionidæ*, and placed by Müller in the order of *Ganoids*, distinguished by the Ganoid (q. v.) scales or bony shields which form the external covering. The gills are free, as in the osseous fishes. The vertebral column is soft; and there are no evident sutures in the skull. Reproduction is by roe, as in osseous fishes. The form of sturgeons is elongated and angular; the plates are arranged in regular rows; the head is cuirassed; the snout long and conical; the mouth is on the under surface of the head, tubular, protractile, and without teeth. The upper lobe of the tail is much larger than the under. The dorsal and anal fins are opposite to one another, behind the ventrals. The air-bladder is very large, and communicates with the gullet by a large hole. The species of S. are numerous, and inhabit both the sea and fresh-water, ascending deep muddy rivers at certain seasons, and temporarily inhabiting lakes. Numerous species are found in the northern parts of the world, although there are none in the Arctic Ocean, or the rivers which flow into it, but the south of Siberia and North America particularly abound in them. They are plentiful in the Caspian and Black Seas, and in the rivers connected with them, where the S. fishery is of great importance, supplying the inhabitants of large districts with their chief article of subsistence, and producing great quantities of Caviare (q. v.), or preserved S. roe, and of isinglass (see GELATINE), for sale. The COMMON S. (*A. sturio*) is sometimes caught

Sturgeon (*Accipenser sturio*).

in the mouths of British rivers, most frequently in salmon-nets; and is a large fish, six or eight feet in length, with five rows of flattened plates; the muzzle long and pointed. Another species (*A. latirostris*), with broader muzzle, also visits the British coasts, but they are not popularly distinguished.

The S. is more abundant on the northern coasts of Europe. It is also found in the more southern parts, and was in very high repute for the table among the Greeks and Romans. At their banquets, it was introduced with particular ceremonies. In England, when caught in the Thames, within the jurisdiction of the Lord Mayor of London, it is a *royal* fish, reserved for the sovereign. Its flesh is white, delicate and firm. It is used both fresh, generally stewed, and pickled or salted.—The largest species of S. is the BIELAGA, or HUSO (*A. huso*), of the Black and Caspian Seas, and their rivers. It attains the length of 20 or 25 feet, and has been known to weigh nearly 3000 lbs. It enters the rivers in winter, while they are still covered with ice. Great part of the caviare of commerce is made from it, and much isinglass, which is merely the air bladder washed, cut into strips, and dried. The STERLET (*A. Ruthenus*) is a comparatively small species, only about three feet in length, found in the same regions, and particularly esteemed for the delicacy of its flesh, and of the caviare obtained from it. There are several other European and Asiatic species; and some of the North American rivers and lakes abound at certain seasons in species of S. which are peculiar to them.—Sturgeons spawn in fresh water, but the young are seldom seen there, and are supposed to descend very early to the sea.

STU'TTGART, the royal residence and metropolis of Würtemberg, is beautifully situated in a widening of the Nesenbach valley, the hills forming a semicircle of eminences clothed with vineyards, orchards, and gardens. The basin in which S. nestles is 897 feet above the sea-level, and enjoys a mild and healthy climate.

Except the very oldest part of the city, the streets are broad, and the buildings handsome. The Schloss, or palace, is a fine modern building. The royal park and gardens extend from the north-east side of the palace for two miles in the direction of Canstatt, have an area of 560 acres, are adorned by fine groups of trees, and intersected by shady avenues, in which all classes may freely walk. The cathedral, built in the 15th c., was gifted by the king, in 1852, with several beautiful painted windows. Other principal buildings are the Royal Theater, public library, Mint, Museum of Art, Polytechnic School, erected in 1860—1865, the post-office, the new synagogue, several new churches and schools, and the Palace of Justice. The new railway station is one of the finest in Europe. The royal library contains 400,000 volumes, 3600 MSS., 9000 Bibles in 80 languages, and 2400 specimens of early printing. S. has many benevolent institutions and societies. There is direct railway communication with the leading cities of Germany and Switzerland. Pop. (1871) 91,623; of whom 78,624 were Protestants, 10,708 Catholics, and 1817 Jews; in 1880, 117,303. Since 1866, and especially since the Franco-Prussian war, trade has increased in a remarkable degree. The principal industries are the manufacture of cotton and half-wool fabrics, iron and tin work, gold and silver articles, chemicals, tobacco, beer-brewing, &c. The export of S. manufactures to North America alone, averaged in late years 4,000,000 to 5,000,000 thalers. S. has a high position in the book-trade, and is the place of meeting of the Booksellers' Union of Southern Germany. S. was the birthplace of Hegel; here, also, Schiller's youth was spent. The name of the city occurs for the first time in 1229. It was besieged by King Rudolph of Hapsburg, 1286—1287, and appears then to have been a place of strength. Between 1634—1638, nearly 9000 people died of the plague; and during the wars of Louis XIV., S. was thrice taken; and again in 1796, 1800, and 1801.

STYE, or STY, is the popular name for a minute boil occurring at the edge of the eyelid, and known to surgeons under the term *hordeolum*. It begins as a small, red, tense swelling, accompanied with considerable itching, and a feeling of stiffness. As the inflammation goes on, the lid may become so swollen as to keep the eye closed. In a few days, matter forms, a white point appears at the apex of the swelling; and when the cuticle gives way, pus and a small slough of connective tissue escape, after which there is a general remission of the symptoms, and the eyelid soon resumes its natural state.

This common affection is chiefly confined to scrofulous and delicate children, but it is sometimes observed in persons of more advanced age. The best local treatment consists in the application of warm-water dressings with lint and oiled silk; and if any hardness remains after the discharge of the matter, dilute nitrate of mercury ointment may be applied. The stye should never be rubbed (notwithstanding the common prejudice in favor of rubbing it with a gold ring), nor, in general, is it necessary to puncture it. To prevent the recurrence of these little boils, attention should be paid to the diet, which should be abundant and nourishing, to the state of the bowels, and to the general health; and tonics may usually be prescribed with advantage. The old form of the word was *stian*.—See Holland's *Plinie*, book xxviii. ch. xi.

STYLE, OLD AND NEW. See CALENDAR.

STYLI'TÉS, See PILLAR SAINTS.

STY'LOBATE, the substructure of a temple beneath the columns. It is sometimes continuous all round the peristyle in the form of three high steps; sometimes it resembles a continuous pedestal along each side, with flights of steps at either end.

STY'PTICS (Gr. *styptikos*, astringent) are agents employed in Surgery for the purpose of checking the flow of blood by application to the bleeding orifice or surface. See BLEEDING.

STY'RIA (Ger. *Steiermark*), a duchy forming one of the German crown-lands of Austria, is bounded on the end by Upper and Lower Austria, E. by Hungary and Croatia, S. and W. by Carniola, Carinthia, and Salzburg. Its area is 8671 English sq. m., and pop. (1880) 1,213,197, who are partly of German and partly of Slavic origin. S. is a mountainous country, being traversed in the west and center by branches of the Noric Alps, which spread out into numerous ramifications; while the southern portion, between the Drave and the Save, is occupied by branches of the Carnic Alps. The climate of S., like that of most mountainous countries, is variable, but is generally raw and cold in the northern and more mountainous portion, and mild in the south. But in spite of its physical character, agriculture is so zealously prosecuted, that $\frac{1}{4}$ths of the country are under cultivation, producing rye, wheat, oats, and maize. Vines are largely cultivated in various parts, and orchards are numerous. The chief wealth of the country, however, lies in its mineral products, which include, besides immense quantities of iron, lead, copper, gold, silver, marble, limestone, and slate, with abundance of salt and coal. The chief industries are thus necessarily in connection with the production of iron and steel, and their manufacture into articles of such excellent quality as to be in great demand in other countries. There are also manufactures of brass and lead articles, earthenware, paper, tobacco, glass, white lead, copper hammers, and of cotton, linen, cloth, &c. S. was anciently divided between Noricum and Pannonia, and

has generally followed the fortunes of the two provinces of Upper and Lower Austria.

STYX (Gr. *stug-*, to hate, abhor), a waterfall in Greece, near the town of Nonacris, in the north-east of Arcadia, descends perpendicularly over lofty and precipitous rocks, and forms a small torrent, which falls into the Crathis. The scenery around it is weird and desolate, so that the Greeks regarded the S. with superstitious awe, the water being supposed to be poisonous, and to break every vessel into which it was put, except those made of the hoof of a horse or an ass. It was reported that Alexander the Great had been poisoned by it. It is now called *ta Mauraneria* (the Black Waters), and also *ta Drakoneria* (the Terrible Waters), the belief in its poisonous qualities still surviving.—In Mythology, the S. was a river of Hades, round which it flowed seven times, and over which Charon (q. v.) conveyed the shades of the departed. As a goddess, S. was the daughter of Oceanus and Tethys, dwelling in a grotto at the entrance of Hades. She was the confirmer of the most solemn oaths of the gods.

SUA'BIA (Ger. *Schwaben*), SWABIA, or SUEVIA, an ancient duchy in the south-west of Germany, so named from a horde of Suevi, who spread over it in the 5th c., and amalgamated with the Alemanni, its previous inhabitants. It existed as a great duchy of the Frank Empire till the 8th c., when Alsace and Rhætia were separated from it, and the remainder, retaining its name of S., was thenceforth governed by *nuntii camerœ*, or royal delegates, one of whom having in 915 usurped the title of Duke of Alemannia, was condemned by the German Diet, and decapitated in 917.

S. at this time was bounded on the W. and S. by the Rhine, on the E. by the Lech (which separated it from Bavaria) and Franconia, N. by the palatinate of the Rhine and Franconia; and contained about 13,000 English square miles. In 918, however, S. was acknowledged as a ducal fief of the Empire; and after changing hands several times, was (1080) bestowed upon Count Frederick of Hohenstaufen (q. v.), the founder of the illustrious House of this name, also known as the House of Suabia. Under the rule of this prince and his successors, S. became the most rich, civilized, and powerful country of Germany, and the ducal court was the resort of the Minnesingers (q. v.); but the wars of the Guelphs and Ghibellines, and the quarrel with the French respecting Naples, put an end to the dynasty in 1268. The ducal vassals in S. rendered themselves almost independent, and professed to acknowledge no lord but the emperor. During these dissensions arose the lordships of Wurtemberg and Baden, with numerous lesser states, holding direct of the crown, and opposed to them the cities, which strove also for an equal independence, and at last, in reward of important service, obtained in 1347 great additional privileges. A number of them united to make common cause against the neighboring feudal lords in 1376 (known as the *First Suabian League*); an opposite league was formed between Würtemberg, Baden, and 17 towns in 1405, called the League of Marbach; and both took part in the war of Swiss independence, the former in support of the Swiss, the latter of the Austrians. At last, the towns, which had been rapidly increasing in wealth and power, decided at Ulm, in 1449, to form a standing army, and a permanent military commission, for the forcible preservation, if necessary, of peace and order; and the Count of Würtemberg, the most powerful of the opposite party, having joined them, was appointed military chief of the league, which ultimately grew up into the *Great Suabian League*, and exercised both administrative and judicial authority over the whole country, effectively repressing feudal quarrels.

In 1512, S. became one of the ten circles into which Germany was now divided, received its complete organization in 1563, and retained it almost without change till the dissolution of the Empire in 1806. But during this period, the wars of the towns with Würtemberg, the Peasants' War, of which S. was one of the foci, the Thirty Years' War, and those between France and the Empire, destroyed the democratic constitution of the towns, and with it their energy, and then their prosperity disappeared, leaving now no relic which could suggest their former great political importance.

SUA'KIN, a seaport belonging to Turkey, on a small rocky island in the Red Sea, off the west coast of Africa, but near the shore, in lat. about 19° 10′ N. It has a good harbor, and a considerable trade, especially in gums; and it is a station for pilgrims passing to and from Africa. Pop. estimated at 8000.

SUARES, FRANCISCO, the most celebrated of the modern scholastic and polemical divines of the Roman Catholic Church, was born at Granada in 1548. His early studies were singularly unpromising; and it is remarkable, in the history of a man afterwards so eminent, that it was not without great difficulty, and after repeated trials, that he obtained admission into the Society of the Jesuits. His later career, however, was brilliant, quite in proportion to the dulness of his first beginnings; and he taught philosophy and theology with remarkable success, first at Alcala, and afterwards at Salamanca, Rome, and Coimbra.

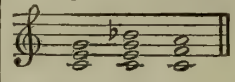
The accounts given of his habits of application to study are almost beyond belief. He is said to have habitually devoted seventeen hours a day to study. Of his power of memory, the marvels related are scarcely less prodigious. He is said to have been able to repeat at will any portion of the whole 23 folio volumes of his own works, even to the quotations from the Fathers and other theological writers with which they abound. S. may truly be described as the ablest and greatest of the modern scholastics; but in his works scholasticism appears in its best form; for although they abound in discussions uninteresting, and indeed unintelligible, to persons unacquainted with scholastic terminology, yet they may also be truly said on each subject to exhaust the whole of the learning, ancient and modern, which existed relating to that subject at the date of their publication. On the philosophy of the ancients S. is especially copious and accurate; and of most of the modern German philosophy we may find the germ in the pages which he devotes to the account of the opinions of the ancients.

In the scholastic controversies on Grace and Free Will, S. was strongly opposed to the Thomistic doctrine; but he also rejected the opposite system of Molina. See MOLINISM. The scheme of reconciling the freedom of the will with the efficacy of grace, and of saving at the same time the doctrine of 'special election,' devised by S., is called *Congruism*, and is explained under the head MOLINA. The works of S. are entirely theological, or ascetic, and were printed in 23 volumes folio at Lyon, Mainz, and Venice. An edition in 28 volumes 4to was completed at Paris in 1861. His treatise *De Legibus* is much esteemed, and has been reprinted in England. S. died at Lisbon in 1617.—See Des Champs, *Vie de Suares* (4to, Perpignan, 1671).

SU'BAHDAR was, under the Mogul government, the title of a governor of a province. It now designates a native officer, holding a rank equivalent to that of captain under the European officers.

SUBA'LTERN, in the Army, or rather in a regiment, is a company officer below the rank of captain; i. e., a lieutenant or sub-lieutenant.

SUBDO'MINANT, in Music, the fifth below the tonic; the note whose dominant is the tonic. Thus F is the subdominant of C, and C of G. One of the keys most nearly related to any key is its subdominant; and the easiest of all modulations is that from a key to its subdominant, which is effected by adding the dominant seventh to the common chord, and the resolution of this chord is the common chord of the subdominant; e. g., in modulating from the key of C to the key of its subdominant F, we have



See DOMINANT.

SUBIA'CO (anc. *Sublaqueum*), a city of the province of Rome, on a hill by the Teverone, 30 miles from Rome. S. possesses a fine cathedral, and many monuments of antiquity. There was a famous Benedictine monastery in S., and here in the 15th century, one of the earliest printing-presses in Italy was established. Pop. 7000.

SUBJECT. See OBJECT.

SUB-KINGDOMS, ANIMAL, a term applied to the great primary divisions of the animal world. The sub-kingdoms are also named 'morphological types,' and this latter term serves to indicate their constitution more definitely than the name 'sub-kingdom.' As an example of the manner in which a 'sub-kingdom' of animals is constituted, we may select that of the *Arthropoda*, a group of animals containing crustaceans, spiders, insects, and centipedes. These, united by Cuvier with the segmented worms to form the *Annulosa* or ARTICULATA (q. v.), are now accorded separate rank. A lobster may be selected as a typical example of this group. In the detailed examination of this animal, we may note that the jointed nature of the tail is perceptible in the fore part of the body, notwithstanding that the latter region consists apparently of a single piece. A further examination of the lobster's body would reveal the fact that each joint and its appendages—the latter being 'paired'—agrees in essential or fundamental structure with every other joint of the body. The investigation of the plan of structure of the lobster's frame would show a very typical arrangement of parts. The *heart* lies dorsally, or on the back. The *digestive system* occupies a median position; and the *nervous system* lies ventrally, or on the floor of the body. The nerve-axis of the lobster further consists, typically, of a double chain of nervous masses (or *ganglia*) united by nervous cords, and from which branches proceed to the various parts of the body. The ideas we may gain regarding the *general type of structure* of the lobster's body, or plan on which that body is built up, may be thus summarized: (1) The body is jointed; (2) the joints and their appendages are fundamentally similar or homologous; (3) the heart lies dorsally, the nervous system ventrally, whilst the digestive system occupies the median position; (4) the append-

ages are in pairs. Now, if we examine the body of any insect, we shall find it to essentially resemble that of the lobster in the general arrangement of its parts.

The body of a spider or a scorpion exhibits a similar disposition of organs to that of the lobster, and shows a fundamentally similar structure beneath variations in appearance and form; and a centipede's body would be found to be also constructed on the lobster-type. The barnacles, water-fleas, crabs, and a whole host of animals more or less nearly allied to the lobster, and belonging to the lobster's class (that of the *Crustacea*), exhibit a near relationship with the typical animal; whilst worms generally (leeches, earth-worms, &c.) would present a fundamental similarity in their characters to those described as existing in the lobster. We thus discover uniformity of type beneath variations in form and appearance, and it is exactly this uniformity or broad structural likeness between apparently different animals which enables us to group them together to form 'sub-kingdoms' or 'types.' A sub-kingdom or type of animals may therefore be defined as consisting of a *number of animals whose bodies are constructed on the same fundamental plan.* Lobsters, crabs, barnacles, &c., insects, spiders, scorpions, and centipedes thus form the 'sub-kingdom' Arthropoda, on account of their agreement in fundamental structure, and in the essential characters just described as being typically exhibited by the lobster. The animal world is thus divided into five or six sub-kingdoms. Between some of these groups recent research—altogether unfavorable to the construction of defined sub-kingdoms or types—has demonstrated connecting links to exist. For a newer and more approved classification, see ZOOLOGY; but one long recognized was as follows:

I. PROTOZOA—Ex.: Sponges, infusoria, amœbæ, and other animalcular forms.
II. CŒLENTERATA—Ex.: Sea-anemones, corals, zoophytes, jelly-fishes, &c.
III. ECHINOZOA—Ex.: Sea-urchins, star-fishes, crinoids, sea-cucumbers, tape-worms, flukes, &c.
IV. ANNULOSA—Ex.: Worms, insects, centipedes, spiders, crustacea.
V. MOLLUSCA—Ex.: Sea-mats, sea-squirts, lamp-shells, shell-fish, cuttle-fishes.
VI. VERTEBRATA—Ex.: Fishes, amphibia, reptiles, birds, mammals.

SUBLAPSA'RIAN, (Lat. *sub-lapsum*, after the Fall), the name given to one section of the school of divines, who maintain the doctrine of absolute decrees of Election and Reprobation. It is possible to conceive God making such a decree in two different ways, either on the hypothesis of His foresight of the fall of Adam, and thus of original sin, or independently of such foresight on his part, and without any reference to such foresight, and entirely out of His own free will and determination. The Sublapsarian system supposes the former; and thus refers the eternal election or reprobation of men by God to His foreseeing that all men would fall in Adam, and thus would deserve eternal reprobation. Out of the entire mass of mankind thus fallen, He freely pre-elects some to life, and equally freely pre-dooms others to death. This distinction is not confined to the Calvinistic schools; it is also found among the Roman Catholics. See SUPRALAPSARIAN.

SUB-LIEUTE'NANT is the junior combatant commissioned officer in the royal navy. When a midshipman has served six years, and can pass in seamanship and certain other subjects, he becomes a sub-lieutenant, and is eligible for promotion to lieutenant, on opportunity occurring. The pay of a sub-lieutenant is £91, 5*s.* a year, and the half-pay, £45, 12*s.* 6*d.* An officer usually serves but a short time in this rank; and, if not promoted earlier, he must retire at 40 years of age. Until within a few years, the sub-lieutenant was called a Mate (q. v.). The establishment is in process of reduction to 250 as a fixed number. In the army, cornets and ensigns are now sub-lieutenants.

SUBLIMA'TION is a chemical process similar to distillation, but differing from it in the nature of the substances to which it is applied. While in distillation, *liquids* are converted by the agency of heat into vapor, which is condensed in the liquid form usually by the cooling action of water; in sublimation, *solid* bodies are reduced by heat to the state of vapor, which reassumes the solid form on cooling. Sublimation is usually conducted in a single vessel of glass or iron, the product being deposited in the upper part of it in a solid state, while the impure residue remains at the bottom; but in the case of sulphur, the vapor is condensed on the walls of a large chamber. Iodine affords a good example of sublimation. On gently heating the lower part of a Florence flask containing a little of this substance, a purple vapor rises, which almost immediately condenses in small brilliant dark purple crystals in the upper parts of the flask, while any impurity that may be present remains at the bottom. Amongst the substances obtained by this process, and employed in the Pharmacopœia, are arsenious acids, benzoic acid, corrosive sublimate, and sublimed sulphur.

SUBLI'ME. Objects indicating great power, vast Expanse, or lofty Elevation, excite in the beholder a feeling of pleasurable elation; and the name 'sublime' is applied both to the objects and to the feeling.

The precise quality in things that arouses this mode of pleasurable excitement, has been variously assigned. According to Burke, *terror* is, in all cases whatsoever, either more openly or more latently the ruling principle, or, at all events, one of the chief sources of Sublimity: Blair suggested that *mighty power or force* is the cause; Payne Knight ascribed it to *mental energy;* Kaimes considers it due to *height or elevation;* Dugald Stewart, in an elaborate essay, affirms that *elevation* is the leading characteristic, and that expanse and power are sublime by suggesting or implying great height; Sir W. Hamilton says that Sublimity requires *magnitude* as its condition, and exists in three forms—Space, Time, and Power.

The feeling itself has also been described variously. If this could be fixed, we should have a key to the objective quality. Longinus characterized it, in reference to literary composition, as 'filling the reader with a glorying, and sense of inward greatness.' Some would call it a 'sense of security' in circumstances of terror or danger. Hamilton describes it as 'a mingled feeling of pleasure and pain—pleasure in the consciousness of the strong energy, pain in the consciousness that this energy is vain.' The connection with the sentiment of Power is generally admitted; but as the comparison of the object with self suggests our own littleness at the same time, there may be a doubt as to whether the emotion is due to the Power, to the Littleness, or to the combination of both.

Referring to the generic sentiment of Power, which is evidently at the foundation, we find that the feeling of superior might in ourselves is cheering, elating, stimulating; and that the sense of littleness or inferiority is a depressing and enfeebling state of mind, a state of pure pain, redeemable in certain circumstances by other feelings, as when our inferiority is only in the comparison with an object of love or veneration; or when it is the condition of some compensating superiority—'the courtier stoops to rise.' The presumption, therefore, is that the elation of the Sublime is connected with the notion of Power. It may be felt although the power is not actually possessed, but imagined, borrowed, or conceived, through a sort of sympathy with the *appearances* of great power or might. If this account of the Feeling be correct, Power must be a principal quality in its Objects; and if with this we combine voluminous sensation (and the corresponding ideas, vastness of expanse and greatness of time), we shall probably be able to explain the Sublime in all its forms.

SUBMARI'NE FORESTS occur at several places around the shores of Britain and Ireland. They consist of beds of impure peat, containing the stools of trees which occupy the sites on which they grew; but by change of level, the ancient forest surfaces are now covered by the tide even at low water. No kind of tree has been found in these forests which does not exist at the present day in the country, and the underwood and herbaceous plants, so far as determined, agree specifically with those found now in similar localities. Submarine forests belong to the Recent or Quaternary period, and occur above the Boulder Clay.

SUBMARINE NAVIGATION. When the Diving-bell (q. v.) had shown that air for respiration can be supplied to persons placed in adequately arranged vessels under water, ingenious men began to speculate on the possibility of navigating closed ships or boats in similarly exceptional circumstances. Cornelius Drebell made a vessel to be rowed under water in the time of James I. In 1774, an inventor named Day lost his life during an experimental descent in Plymouth Sound, in a vessel of about 50 tons burden. Mr. Bushnell, of Connecticut, in 1775, and Robert Fulton, about 1796, contrived submarine vessels, intended to be used in warfare. The vessel patented in 1859 by Mr. Delaney of Chicago, was egg-shaped in transverse section, and diminished nearly to a point at each end. It had two iron tanks in the interior; one had air forced into it by an air pump; the second contained water. The engineer of the boat, by pumping water into or out of the second tank, through the action of the air in the first, could raise or lower the boat to different depths in the water.

SUBO'RDINARY, or SUBO'RDINATE ORDINARY, in Heraldry, a name given to a certain class of charges mostly formed of straight or curved lines. Heralds vary a little in their enumeration, but the following are generally held to come within this category: the Bordure, the Orle, the Tressure, the Flanche, the Pile, the Pall, the Quarter, the Canton, the Gyron, the Fret, the Inescutcheon, the Lozenge, the Fusil, and the Mascle. See these heads; also ORDINARIES.

SUBORNA'TION OF PERJURY is the offence of procuring another to take such a false oath as constitutes Perjury (q. v.) in that other. It is a misdemeanor, punishable anciently by death; afterwards banishment, or cutting out of the tongue; then forfeiture of goods; and latterly, as at present, by fine and imprisonment.

SUBPŒ'NA, in English Law practice, means the writ or process by which the attendance of a witness in a court of justice is compelled. It is a writ in the Queen's name, commanding him to lay aside his business and all excuses, and attend at the time and place indicated, under a penalty of £100. If the witness is required to produce a document, the writ is called a *subpœna duces tecum*. If the witness do not attend, and has not a good legal excuse, such as dangerous illness, he may be sued in an action of damages, or committed to prison.

SUB RO'SA, 'under the rose'—i. e., between ourselves, or in secrecy. It was customary among the ancient Germans, on occasions of festivity, to suspend a rose from the ceiling above the table, as a symbol that whatever was said during the feast by those present would be afterwards forgotten, or at least be kept as a secret among themselves.

SU'BSIDIES, a term in Politics, used in two different senses: 1. It is applied in English political history to taxes levied not immediately on property, but on persons, in respect of their reputed estates in lands or goods; or customs imposed on any of the staple commodities in addition to the *costuma magna et antiqua*. Thus, 30,000 sacks of wool were granted to Edward III. in 1340, in aid of the war with France. Subsidies were granted on various occasions to James I. and Charles II. 2. The same word is used to denote money paid by one state to another, in order to procure a limited succor of auxiliary troops, ships of war, or provisions. In the time of the war with the revolutionists of France and Napoleon I., Great Britain furnished subsidies to foreign powers to a large extent, in order to engage them to resist the progress of the French. In questions regarding subsidies, it is held that the state furnishing the succor does not thereby become the enemy of the opposite belligerent: it may remain neutral in all respects, except as regards the auxiliary forces supplied. Such, for example, was long the attitude maintained by the Confederate Cantons of Switzerland: while granting troops to the various European powers, they were in the habit, at the same time, of preserving a rigorous neutrality. The service of Swiss regiments abroad is no longer sanctioned. The federal constitution of Switzerland, of 12th September 1848, prohibited the conclusion of military capitulations; and on 30th July 1859, a proclamation was issued by the Federal Council, forbidding any Swiss subjects from taking service under a foreign power, without the authorization of the council.

SUBSTANCE, a word connected with certain discussions in Logic and Metaphysics. Substance is correlative with Quality or Attribute. Every substance must have attributes, and every attribute must be the attribute of some substance. The substance gold has the attributes weight, color, &c. But as every power or property of a thing, every way that the thing affects us, may be called an attribute or quality, if all the attributes are counted off, there is nothing left; and the question then arises: What is the *substance?* To avoid this seeming inconsistency, it was assumed that everything whatsoever possesses, besides its attributes, an unknown substratum that they rest upon, or inhere in—a mystical and inscrutable bond, that holds the attributes together, without being itself an attribute. This gratuitous assumption of what is, after all, a nonentity, was repudiated by Locke and others, who found a meaning for substance without departing from the knowable. Every object has some *essential* or *fundamental* quality, which being present, it preserves its identity; and which being removed, it is no longer the same object, but another. Thus, the substance of Body or Matter is not the remnant after all the qualities are subtracted; it is the two fundamental and inerasable qualities, Extension and Resistance. Size, shape, color, heat, odor, &c., may all be varied; but so long as Extension and Resistance, in any degree, are found, we have a piece of matter. On the same view, the substance of Mind is whatever we regard as its fundamental essence, or distinguishing marks. We may adopt Feeling, or Volition, or Intellect, or require a share of all three, according to our mode of defining the mind. It would, then, be a mere confusion of language to talk of Feeling, Volition, and Intellect as *inhering* in mind; they *are* mind, and there is nothing besides.

Notwithstanding the obviousness of this explanation, the employment of the words Substance and Attribute has led to such an inveterate demand for something that shall underlie all attributes—a substance of body and a substance of mind—distinct from anything meant by the names, that many philosophers have considered it necessary to preserve the phantom as a thing of belief, if not of knowledge. The doctrine of an unknowable substance in the abstract very early allied itself with the popular theory of the Perception of a material world (see PERCEPTION), and the same arguments are good, for or against both. Other names for expressing the same contrast are *noumenon* and *phenomenon*. The Phenomenon is what shows itself to our senses, or is conceived by our intelligence—the qualities of extension and resistance in body; and of feeling, &c., in mind. The Noumenon is something apart and beyond, something inconceivable and unknowable, but which, say some, we are instinctively led to believe in. Thus, in the great question above alluded to—the belief of an independent material world—the phenomenal manifestations are inextricably involved with our mental powers of conceiving, and would vary, if these were to vary; consequently, they cannot be the absolute, independent, self-existent reality; which drives one school of philosophy upon the expedient of believing in such a reality, although it must be for ever incomprehensible to us.

SU'BSTITUTE, MILITARY. In nations where conscription is resorted to for the supply of soldiers for the army, the lot often falls on those unwilling to serve in person. In such a case, the state sometimes agrees to accept the services of a substitute who is of equally good physique. Unless the levy be very extensive, or the term of military service very long, substitutes are readily found among military men who have already served their prescribed period. Of course, the substitute must be paid for the risk he runs. His price depends, like all other saleable articles, on the demand and supply. Happily, in Great Britain, few of those now living have ever known when substitutes were necessary. It is, however, to be remembered that the act for a militia ballot hangs continually over us, and is only suspended by a special act of parliament from year to year.

SUBSTITU'TION is one of the three principal methods employed in examining the chemical composition of organic bodies, and in tracing their relation to other compounds; the two other methods being those of *oxidation* and of *reduction*. Although the term is restricted to organic chemistry, the ordinary method of preparing insoluble inorganic compounds by double decomposition is in reality a case of substitution of one base or one acid for another. If, for instance, solutions of nitrate of lime and sulphate of soda are mixed together, the resulting compounds are sulphate of lime and nitrate of soda, in which the lime is substituted for the soda, and the soda for the lime. In some cases, an element may be replaced (or, more correctly, displaced) by a compound group; thus, cyanogen, C_2N, may take the place of oxygen, as, for example, in the reaction that ensues between hydrocyanic acid and red oxide of mercury, when cyanide of mercury and water are formed, as shown in the equation: $H(C_2N) + HgO = Hg(C_2N) + HO$.

Similarly, the groups NO_4, SO_2, and NH_2 may often be substituted for hydrogen. In various organic bodies, one or more atoms of hydrogen may be displaced by one or more atoms of chlorine, a fact which was originally observed by Gay-Lussac in noticing the action of chlorine on wax. The new product thus formed is almost always analogous in its nature to the compound from which it is produced; thus, according as the substance acted on by the chlorine is an acid or a base, the resulting product is an acid or a base, and the number of atoms is always the same in the original substance and the product. The following examples will elucidate the above remarks: If acetic acid, $C_4H_4O_4$, be exposed to the action of chlorine, we obtain, according to the duration and modifications of the action, the two compounds, monochloracetic acid, $C_4H_3ClO_4$, and trichloracetic acid, $C_4HCl_3O_4$, in the former of which, one atom, and in the latter, three atoms of hydrogen, are displaced by a corresponding number of atoms of chlorine. Hydrochloric ether, C_4H_5Cl, may be made to yield the following succession of compounds, in which a gradually increasing amount of the hydrogen is displaced by chlorine, until, in the final result, the hydrogen has altogether disappeared. The consecutive compounds thus resulting from hydrochloric ether, C_4H_5Cl, are (1) chlorinated ether, $C_4(H_4Cl)Cl$; (2) dichlorinated ether, $C_4(H_3Cl_2)Cl$; (3) trichlorinated ether, $C_4(H_2Cl_3)Cl$; (4) tetrachlorinated ether, $C_4(HCl_4)Cl$; and (5) sesquichloride of carbon, $C_4(Cl_5)Cl$. 'The chlorine,' says Professor Miller, 'appears to have taken the place of hydrogen in the group without disturbing the relative position of the other elements which enter into its formation; just as a brick in an edifice may be conceived to admit of being removed, whilst its place is supplied by a block of wood or of stone, without altering the form or symmetry of the building.' Substitutions of bromine and iodine for hydrogen may be effected in the same way as has been shown to occur in the case of chlorine.

The study of the artificial formation of organic bases has led to the discovery of many remarkable instances of substitution products. If, for example, bromide of ethyl, C_4H_5Br, is heated in a sealed tube with a solution of ammonia in alcohol, hydrobromate of ethylia (or ethylamine) is formed, and on distilling this vapor with hydrate of potash, one of the products is a new base, ethylia, C_4H_7N, which may be regarded as ammonia, NH_3, in which one atom of hydrogen has been displaced by one atom of ethyl, C_4H_5.

By a similar proceeding, we may successively displace the second and the third atoms of the hydrogen in the ammonia; and we thus obtain two more complex bases, diethylia, $C_8H_{11}N$, and triethylia, $C_{12}H_{15}N$.

SUBTRA'CTION, one of the four fundamental processes of Arithmetic, is the diminution of a quantity by the removal of a certain portion of it. It is consequently the reverse of *Addition*, and determines how much of any quantity remains after a certain quantity has been taken from it. In cases where the digits of the number to be substracted are greater than the corresponding ones of the number to be diminished, two methods of operation may be adopted.

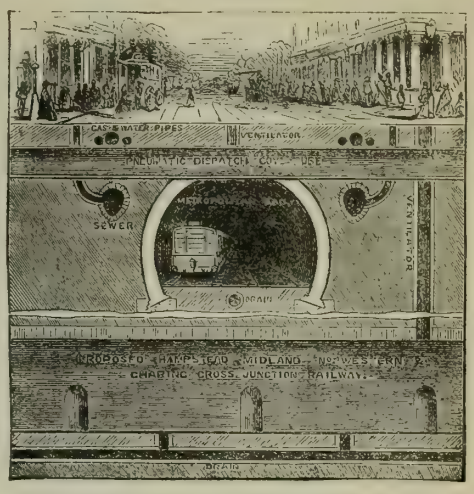
(1)	(2)	(3)
7324	7 (13) (12) 4	6 (12) (12) 4
1842	(2) (9) 4 2	1 8 4 2
5482	5 4 8 2	5 4 8 2

For example, in substracting 1842 from 7324, the numbers are written as in form (1). The method of operation usually followed is to make an addition mentally to the upper figure when necessary, and then compensate for this by an equivalent addition to the next under figure, as represented in form (2). Thus, 10 'tens' are added to 2 'tens,' to enable 4 'tens' to be subtracted, and this addition is compensated for by an equal increase of the under line by 1 'hundred,' through the change of 8 'hundreds' into 9 'hundreds.' The more simple and directly intelligible plan, shown in form (3), is to borrow a unit of the next higher degree in the upper line, care being taken to remember, in the partial subtraction immediately succeeding, that the upper digit must be considered as less by unity than it appears.

SUBWAYS. The system of engineering *beneath* the public streets has not by any means yet reached its full development. Subways for foot-passengers are occasionally constructed in connection with railway termini: one such connects the Bishopsgate Street station of the Metropolitan Railway with the Liverpool Street station of the Great Eastern; another connects two Victoria stations at Pimlico, belonging to different lines and companies. The *Tower Subway* is a remarkable instance of a passage under the Thames for foot-passengers. The Metropolitan or Underground Railway, opened in 1863, was the first example of its kind; the passengers going down stairs from the side-pavements to stations underneath the carriage-way. The pneumatic propulsion of mail-bags (see PNEUMATIC DISPATCH) has given rise to projects for a similar mode of propelling railway trains beneath streets and roads. One such, the Waterloo and Whitehall Railway, was commenced about 1865, to pass under the Thames; want of funds led to its abandonment after shafts had been sunk. The term *subways* is usually applied, not to such tunneled passages for traveling, but to roomy archways that will contain sewer-pipes, water-pipes, and gas-pipes. It has been long considered a defective system that whenever such pipes need repair, the surface of the street has to be broken up to get at them, thereby causing great expense and great interruption to traffic. When the Metropolitan Board of Works commenced their series of improvements, they resolved on the trial of subways for this useful purpose. They began with a new street, extending from Covent Garden Market to St. Martin's Lane, opened in 1861. Underneath the carriage-way of this street, there is a subway, a central arched passage or tunnel 12 feet wide by 6½ feet high; with arched side-openings for house service-pipes, connected with the cellarage of the several dwellings.

In this subway are water-pipes, gas-pipes, and electro-telegraphic wires, all easy of access by side entrances to the subway, of sufficient size to admit workmen, pipes, &c. In this instance, the main sewer is not in the subway itself, but underneath it, provided with man-holes, gullies, ventilating shafts, &c. A second example is afforded by Southwark Street, lately formed from Blackfriars Road to the southern foot of London Bridge. Underneath this street extends a subway, excellently planned for the purposes above mentioned. Two street lamp-posts, of unusually elegant design, one at each end of the street, act as ventilating shafts for the subway; and there are other ventilators along the route, besides side entrances for workmen. A curious proof has been furnished, however, of the anomalies which so frequently mar our public works. In 1865, a gas company broke up the roadway, and broke through the well-built crown of the arch of the subway, to get at their gas-pipes for purposes of repair or adjustment. It was found, on investigation, that no one had power to prevent them. The act empowered the Metropolitan Board of Works to make a subway for the use of gas companies, water companies, &c.; the gas company, on the other hand, were empowered by *their* act to break up the public roadways to get at their pipes; the Board could not compel the company to adopt the new plan, because the powers were only permissive, not obligatory. The water companies and gas companies fear incurring additional expense; and there is known to be a difference of opinion among engineers concerning the danger from leakage and explosion when the two sets of pipes are enclosed in the same archway.

The subway system, after overcoming these and other difficulties, has made a great advance within a recent period. Queen Victoria Street, and several other new streets, have been provided with subways similar to that under Southwark Street. The Victoria or Northern Thames Embankment presents some fine examples of subway engineering. Between the masonry of the river-wall and the former line of high-water, there are no less than



Singular Project in Subway Engineering.
(From *Illustrated London News*.)

three tunnels or arched passages under the surface of the ground parallel to the course of the river. One is the Metropolitan District Railway; another is the Low-level Sewer of the Great Main Drainage System; while a third is a subway to contain gas and water pipes, telegraph wires, &c. The most extraordinary plan, perhaps, ever seriously proposed in subway engineering is connected with the spot where Tottenham Court Road, Euston Road, and Hampstead Road join. The Metropolitan Railway is here flanked on either side by sewers; above it, but below the level of the street, are several gas and water pipes, drains, and ventilating shafts; while crossing immediately over the Metropolitan Railway, at right angles, is the tube of the (still abortive, 1880) Pneumatic Dispatch (q. v.). Beneath all this is shown in the woodcut the section of another tunnel, intended to join the Midland and North-western Railways with the South-eastern. Civil engineers and contractors are ready to grapple with the difficulties of this extraordinary work whenever financial circumstances are favorable.

SUCCE'SSION is a legal term used in Scotland, but not used technically in England, where the same subject is spoken of under the name of Next of Kin (q. v.), and Descent; see also INTESTACY, STATUTES OF DISTRIBUTIONS, EXECUTORS, ADMINISTRATOR. In Scotland, the term is used to denote the taking of property by one party in place of another. Where the devolution takes place in consequence of a conveyance from the proprietor, the acquirer is termed a singular successor, as the conveyance is the single title under which he acquires. Where, however, the person dies intestate, his heir succeeds to the whole of the heritage, and is called the universal successor. Where no will or disposition by the owner is executed, the law makes a disposition for him, and distributes the property according to certain rules of relationship by blood. 1. In the case of heritable succession, Primogeniture (q. v.) is the rule, the eldest son and his issue taking the property; and after that stock is exhausted, the next eldest son; and so on. When males fail, then the succession opens to the daughters, who take not in order of seniority, but all together, and are called Heirs-portioners (q. v.). When descendants fail, then the succession goes to collaterals; thus, brothers and sisters succeed first—the brothers according to a certain priority, and, failing them, the sisters all together as heirs-portioners. When the descendants and collaterals are exhausted, the succession then goes to ascendants (the mother, however, being entirely excluded), the father first, and then uncles and aunts, &c. In heritable succession, the right of representation exists, i. e., when an heir is dead, his children represent him, and take that share which, if alive, he would have taken. Brothers and sisters consanguinean, i. e., by the same father, but not by the same mother, succeed after brothers and sisters german (i. e., by the same father and mother), before the remoter line of the full blood.

The English law of descent or succession differs considerably from the above. See INTESTACY, and Paterson's *Comp. of Eng-*

lish and Scotch Law (2d ed.), s. 751, *et seq.*—2. As to succession in movables, or to the personal property of the intestate, see KIN, NEXT OF. There are taxes called succession duties, which are payable to the revenue on all property, real and personal, acquired by succession. The duty payable on lineal issue or lineal ancestors is 1 per cent.; by brothers and sisters and their descendants, 3 per cent.; and so on, the duty increasing as the relationship is more distant. The husband or wife of the proprietor is exempted from the duty.

SUCCESSION ACTS. From a comparatively early period in English history, parliament occasionally exercised the power of limiting or modifying the hereditary succession to the throne. The first instance of such interference occurred in the reign of Henry IV., who possessed himself of the crown, to the prejudice of the descendants of Lionel, Duke of Clarence, second son of Edward III. Act 7 Henry IV. c. 2 confirmed the title of that monarch, and declared Prince Henry heir-apparent of England and France, with remainders to Henry IV.'s other children. Parliamentary interposition was subsequently exercised in the case of Henry VII. and in regard to the immediate successors of Henry VIII. The respective rights of James I., Charles I., and Charles II. were acknowledged by parliament; and in the case of Charles II. the crown was held to have devolved on him immediately on the death of his father.

The revolution of 1688, was founded on the so-called abdication of the government by James II. See ABDICATION. The Convention bestowed the crown on William and Mary for life, and regulated the claims of Anne. On the impending extinction of the Protestant descendants of Charles I., the crown was settled by 12 and 13 Will. III. c. 2, in the event of the death of William and Anne without issue, on the next Protestant line, according to the regular order of succession—viz., the descendants of the Electress Sophia of Hanover, granddaughter of James I.; and it was at the same time enacted, that whoever should hereafter come to possession of the crown, should join the communion of the Church of England as by law established. This is the latest parliamentary limitation of the crown; but the right of parliament to limit the succession has been secured by 6 Anne, c. 7, which attaches the penalties of treason to the 'maliciously, advisedly, and directly' maintaining, by writing or printing, that the king and parliament cannot make laws to bind the succession to the crown, and the penalties of a *Præmunire* (q. v.) to maintaining the same doctrine by preaching, teaching, or advised speaking.

SUCCESSION WARS were of frequent occurrence in Europe, between the middle of the 17th and the middle of the 18th centuries on the occasion of the failure of a sovereign house. The most important of these wars was that of the Orleans succession to the Palatinate (1686—1697), closed by the peace of Ryswick; of the Spanish succession (1700—1713); of the Polish succession (1733—1738), closed by the peace of Vienna; of the Austrian succession (1740—1748); and of the Bavarian succession (1777—1779), called, in ridicule, the Potato-war. Of these, the second and fourth were by far the most important, and a brief notice of their course and conclusion is subjoined.

SUCCESSION, WAR OF THE SPANISH, arose on the death, without issue or collateral male heirs, of Charles II., king of Spain, 3d November 1700. The nearest natural heir to the throne was of the royal line of France, Charles's elder sister having married Louis XIV.; but to prevent any possible union of the two crowns, a solemn renunciation had been exacted both from Louis and his queen, for themselves *and their heirs;* and this renunciation having been ratified by the king and Cortes of Spain, was made as binding as legal forms could make it. Failing the Bourbons, the next heirs were the descendants of the younger sister of Charles, who had married the Emperor Leopold I., and from whom no renunciation had been exacted; and the only issue being a daughter, who had married the Elector of Bavaria, and borne a son, Joseph-Ferdinand, this prince was during his lifetime regarded both by Charles II. and the Spanish people as the rightful heir. But dying in 1699 without issue, the question of succession was reopened, Louis XIV., failing his wife's rights, claiming for himself, as the son of Philip IV.'s elder sister (being, however, again legally barred here by another solemn renunciation); while the Emperor Leopold, maintaining with justice that the Bourbons were by these two renunciations wholly deprived of all their rights of heirship, claimed the throne as the son of Philip IV.'s younger sister. The other powers of Europe, especially Britain, Holland, and Germany, warmly interested themselves in the matter, as a question of policy, and with good reason; for not only was the crown of Spain a valuable prize in itself, carrying with it the sovereignty of the Netherlands, the Milanese, Naples and Sicily, and immense possessions in America, but its union with France or Austria would of a certainty endanger the independence of every other sovereignty in Europe.

Both claimants bade for the support of the maritime powers, the one by renouncing his claims in favor of his second grandson, Philip of Anjou, the other by putting forward his second son, Charles, as his substitute, while both solemnly promised never to undertake the union of the two crowns. The Austrian party at first preponderated in Spain; but Louis, by able and unscrupulous policy, succeeded in undermining the Austrian influence at Madrid, and in having Philip declared the heir (October 2, 1700). On the death of King Charles, a month after, Philip appeared in Spain, and was well received by all classes, and at once recognized as monarch, an example gradually and unwillingly followed by all the European powers excepting the emperor; for at that time the dread of Louis XIV.'s power pressed like an incubus on the nations of Europe. However, the French monarch, by various ill-advised acts, chiefly by his support of the elder Pretender (the son of James II.), whom he recognized as sovereign of Britain, and by occupation of the Netherlands and menacing treatment of Holland, stirred up such general resentment, that William III. was enabled to revive the *Grand Alliance*, and his successor, Anne, to join with Holland and Austria in declaring war against France and the 'Spanish usurper,' 15th May 1702.

Hostilities at once commenced; a combined British-Dutch-German army under Marlborough attacked the French in Belgium, and captured one by one their fortresses on the Maes, while the Reichs army (Germany having declared for Austria), under the Markgraf of Baden, crossed the Rhine, and took Landau. Austria herself had, however, commenced the contest in the previous year, by sending into Italy Prince Eugene (q. v) of Savoy-Carignan, at the head of a veteran army of 32,000 men, who did a good deal of hard fighting, with no adequate result. Meanwhile, the Elector of Bavaria raised an army and declared for France, and a French army under Villars marched to join him. Both were kept in check by the Markgraf for some time; but, in the summer of 1703, Villars burst through the Black Forest, and joined the elector, with the view of penetrating through Bavaria into Austria, but his obstinate ally, the elector, was determined to invade the Tyrol instead, and join Vendome in Northern Italy—a scheme which ended most disastrously; and Villars returned in disgust to France. In the Low Countries, Marlborough employed himself in gradually depriving the French of their strongholds: in Italy, the Austrians were driven from point to point, till nothing remained to them but a few districts on the Po; they were, however, relieved towards the close of the year by the defection from France of the Duke of Savoy, who joined the grand alliance 25th October 1703, an event which compelled Vendome to return to Piedmont. The first great blow was struck in the following year, when the combined Austrian-German-British army, under Marlborough, totally defeated the French and the elector at Blenheim (q. v.), driving the débris of their forces almost to the foot of the Vosges. After this, the French never obtained a permanent footing in Germany. The campaigns of Marlborough in Germany, and of Eugene in Italy, in 1705, were successful but not very important.

The year 1706 was another great epoch in this protracted contest; the British and Dutch having freed the valley of the Maes, had forced the French into South Brabant, and Marlborough having, by a stratagem, caused them to march towards Namur, suddenly attacked them at Ramillies (q. v.), and, after a brief combat, put them completely to rout with great slaughter, the elector and Vileroy, the joint commanders, narrowly escaping capture. Louis hastily reinforced his army, and recalled Vendome from Italy to take the command, a step which, however necessary, cleared the way for Eugene who completely out-generalled his opponent Marsin, and after a memorable march of 34 days, appeared before Turin, and united with the Duke of Savoy. The battle of Turin, in which the gallant Marsin was slain, was one of the most obstinate of the whole war, but its result was as decisive, and from this period the French power in Northern Italy was shattered; and the following year saw the country completely cleared of both French and Spaniards. From 1706 the war in Germany was purely defensive, and no battle worthy of notice was fought. In Italy also the contest on the whole languished, though the Austrian arms were for the most part successful, Mantua and Naples (1708) being subdued, and the pope compelled to preserve neutrality by dread of another sack of Rome. But since the commencement of 1704, another theater of war had been established by the landing of the Archduke Charles at Lisbon with 8000 British and 6000 Dutch troops, who were joined by the Portuguese (their king having acceded to the alliance against France), and invaded Spain from the west; but nothing of consequence was established till a landing had been effected by the Earl of Peterborough (q. v.), with a small body of troops in Catalonia. Then attacked both from the west and east, the Bourbon forces were beaten and driven across the Pyrenees, and it was only after the departure of Peterborough that Berwick (q. v.) made head against his antagonists. By his victory at Almanza (25th April 1707), he recovered the whole of Spain except Catalonia.

In 1710 Berwick finally left Spain; and the Carlists under Stanhope and Starhemberg again got the upper hand, repossess-

ing themselves of the east of Spain, and of Madrid (28th of September). But the arrival of Vendome speedily changed the face of affairs. Stanhope was defeated and captured (9th December) at Brihuega, and Starhemberg was forced to retreat on the following day. The war was thenceforth confined to Catalonia, and was distinguished by no noteworthy incidents. The most important part of the struggle had been meanwhile taking place in the Netherlands, where Marlborough (1707) drew up in concert with Eugene a secret plan of operations which effected a division of the Moselle army under the elector and Berwick from that of the north under Vendome; whereupon the British and Germans swiftly uniting fell upon Vendome's army at Oudenarde (q. v.) (1708), and before Berwick could come up to its aid, inflicted upon it a severe defeat. The capture of Lille, Ghent, and Bruges necessarily followed. France now began to show symptoms of exhaustion, and made overtures of peace, but these being chiefly illusory, were rejected; and the emperor having largely reinforced Eugene, the allies took the field with 110,000 men, while the French, equal in strength, were now directed by Villars, the most enterprising and fortunate of their generals; but his star, which had hitherto been constantly in the ascendant, fell before that of Marlborough at Malplaquet (q. v.) (September 1709). After some further campaigning, besieging, and negotiating, the opportune death of the emperor (April 17, 1711) rescued France from the brink of destruction; for Britain became lukewarm in support of a cause which would effect the reunion of Austria and Spain; and the Tories having come into power, private preliminaries of peace were signed between Britain and France, 8th October, 1711. Eugene, however, continued the war, aided by Holland, and captured Quesnoy; but the defeat and capture of the Earl of Albemarle and the British contingent at Denain (July 1712) so weakened his force, that he was compelled to give way; and in the following spring the Dutch joined the British as parties to the peace of Utrecht (q. v.). The Emperor Charles was also forced to conclude a treaty of peace at Baden, 7th September, 1714, which ended the struggle, leaving Philip in possession of the Spanish throne (see UTRECHT, PEACE OF); while Austria obtained the Spanish Netherlands and the Milanese.

SUCCESSION, WAR OF THE AUSTRIAN. The death of the Emperor Charles VI. (20th October 1740), by which the male line of the House of Hapsburg became extinct, was the signal for a general uprising of the powers of Europe, some to prey on the Austrian possessions, and others to aid the eldest daughter and heir of the deceased emperor. The probability of such a contingency had long been foreseen by Charles VI., for as early as 1713 he had published a *Pragmatic Sanction* (q. v.), stipulating that, in default of male heirs, the whole of his dominions should descend undivided to his eldest daughter, Maria Theresa (q. v.); and it was almost his sole aim, during his subsequent reign, to gain the consent of all parties having proximate claims to any of the Austrian domains, and of the principal powers of Europe, to this arrangement. The Elector of Bavaria, Charles-Albert, alone refused to resign his pretensions. On the death of her father, Maria Theresa intimated her accession to the various European powers, and from all of them, except France and Bavaria, received assurances of good-will and support; but notwithstanding, two months did not elapse till Frederick II. of Prussia, without a declaration of war, invaded Silesia. The Austrian treasury was at this time exhausted, and the army much disorganized; so that little or no effective resistance could be made to the Prussians; while the state of alarm into which this sudden attack had thrown the court of Vienna was increased by doubts as to the intentions of France. These doubts were soon resolved by the latter, in the spring of 1741, forming a confederacy of all the claimants to the Austrian dominions—the electors of Bavaria and Saxony, sons-in-law of the Emperor Joseph I.; Philip V. of Spain; Charles-Emmanuel of Sardinia, who claimed the Milanese; and Frederick II. of Prussia, who *now* demanded almost the whole of Silesia.

On the other hand, Britain granted Maria Theresa an annual subsidy of £300,000; the Dutch were willing to aid her when opportunity offered; and Hungary gallantly responded to her pathetic appeal by sending in thousands her motley population, Magyars, Croats, Slavs, and Tolpatches, to fight in defence of their heroic queen. Meantime the Bavarians, in conjunction with the French under Belleisle, overran the greater part of Bohemia This invasion compelled the queen to buy off her most formidable opponent, Prussia, by the surrender of Silesia and Glatz; and then, while Prince Charles of Lorraine kept the French at bay in Bohemia, Khevenhuller, the most enterprising of the Austrian generals, advanced up the valley of the Danube, captured 12,000 French in Lintz, overran Bavaria, and on the very day of the elector's coronation as the Emperor Charles VII., took Munich his capital (12th February 1742). But this great success alarmed Frederick II. for the security of his new possessions, and abruptly breaking the treaty, he poured his forces into Bohemia and Upper Austria, and gained the battle of Chotusitz (17th May). The same year witnessed increased activity on the part of Britain (the Walpole administration being now in power) and Holland on behalf of Austria; the expulsion of the French and Bavarians from Bohemia; the severance of the king of Sardinia from the coalition against Austria, produced by the bribe of some districts of the Milanese, which, however, he did not obtain till some time afterwards; the enforcement of neutrality upon Naples by the threatening attitude of a British fleet off the capital; and, on the other hand, the recovery of Bavaria by the elector.

In May 1743, Bavaria again fell into the hands of Prince Charles and Khevenhuller; Count Saxe was driven with great loss from the Palatinate; the 'Emperor' Charles-Albert and the Swedes, disgusted at their ill-success in the war, retired from the contest, so that France and Spain now remained the sole representatives of the once mighty coalition. In 1744, France and Britain, which had hitherto engaged in the conflict only as allies, declared war on each other; and the latter proceeded to destroy piecemeal the French and Spanish shipping on the high seas, and to attack their colonial possessions. For this, however, the successes of Saxe in the Netherlands were a compensation. However, the great successes of Austria on the Rhine, and the ill-concealed ambitious projects of Maria Theresa, again alarmed Frederick II. for Silesia; and he resolved on another attempt to rivet his hold on the much-coveted province before it was too late. Accordingly, he concluded at Frankfurt (May 13, 1744), a secret convention with France, the emperor, the elector-palatine, and the king of Sweden. Bursting into Bohemia with his usual celerity, Frederick II. forced the Austrians at once to return from Alsace, thus enabling the elector to recapture Bavaria; but before Prince Charles had time to reach Bohemia, a fresh levy of 44,000 men, which had been raised by the chivalrous and patriotic Hungarians, joined by 6000 Saxons, had reached the Prussians, and by cutting off their supplies, and capturing their stragglers and foraging parties, compelled them to evacuate the kingdom with considerable loss. In Italy, the Spaniards, who were now joined by the Neapolitans, were defeated repeatedly, and compelled to retreat down the peninsula; and the king of Sardinia succeeded in preventing the French from effecting a permanent lodgment in North-west Italy. In January 1745, the emperor-elector died, and his son, Maximilian-Joseph, profiting from his father's misfortunes, declined to take part in the contest, or to allow himself to be nominated emperor, and made peace with Austria.

Frederick II., displeased with the meddling and overbearing conduct of France with respect to the approaching imperial election, also sought to come to terms with Austria, by the mediation of Britain, and the peace of Dresden (25th December 1745) finally withdrew Prussia from the conflict. In Flanders, the fortunes of Austria also declined; and after the victory of Fontenoy (11th May 1745) she could not prevent Saxe from capturing the chief Belgian fortresses in succession. In Italy, also, fortune declared for the coalition; for the Spanish-Neapolitan army, now reinforced by the Genoese and Modenese—70,000 men in all—defied all opposition, overran the whole of Lombardy and much of the Sardinian territories, driving the king under the walls of his capital. Similar reverses befell the allies in Flanders during the campaign of 1746; but these were more than counterbalanced by the great successes obtained in Italy, where all the lost fortresses of Lombardy, Parma, and Guastalla, were recaptured, the coalition army totally routed in a great battle near Placentia (June 16), and Genoa overrun and occupied. Another of fortune's favors to Austria was the death of Philip V. of Spain (July 9), which, by depriving that archplotter, his queen, of the supreme power, considerably diminished the zeal of the Spanish court in the prosecution of the war. In 1747, the Dutch, who had hitherto escaped the ravages of war, were made practically acquainted with them by Saxe, who, having completely subdued the Austrian Netherlands, invaded and overran Dutch Flanders, routed the unfortunate Duke of Cumberland at Laffeldt (2d July), while his celebrated chief of engineers, Count Lowendal, after a two months' siege, took Bergen-op-Zoom, Cohorn's masterpiece, a fortress believed by the Dutch to be impregnable.

At the commencement of 1748, Britain, France, and Holland sought to bring about a peace, and agreed among themselves to certain preliminaries, which were submitted to Austria and Sardinia; but as one of them was the surrender of Parma and Placentia to Don Philip of Spain, the former refused her consent; and her two allies, disgusted at her disregard of the sacrifices they had made on her behalf, at once signed the preliminaries (30th April), and Austria sullenly followed suit on May 18. Much discussion followed, but on the 18th October 1748, the treaty of Aix-la-Chapelle (q. v.) put an end to this most disastrous war, which left the Hapsburgs in possession of their hereditary dominions, with the exception of Silesia and some of their Italian provinces. See AIX-LA-CHAPELLE.

SUCCI'NIC ACID ($C_8H_4O_6.2HO$) derives its name from its having been originally found in amber (Lat. *succinum*), and is one

of the group of dibasic acids of the oxalic acid series, whose general formula is $C_{2n}H_{2n-4}O_4.2HO$. Succinic acid occurs as a natural constituent not only in amber, but also in the resins of many of the pine tribe, in the leaves of the lettuce and wormwood; and, in the animal kingdom, it has been detected in the fluids of hydatid cysts and hydrocele, in the parenchymatous juices of the thymus gland of the calf, and of the pancreas and thyroid gland of the ox.

One of the most important points in connection with succinic acid is its convertibility into tartaric acid, while tartaric acid may in its turn be reconverted into succinic acid.

SU'CCULENT PLANTS are those plants remarkable for the thick and fleshy or succulent character of their stems and leaves. This character prevails in the natural orders *Cactaceæ*, *Mesembryaceæ*, and *Crassulaceæ*, but frequently appears also in genera of other natural orders, as in aloes and some other *Liliaceæ*. It consists in a peculiar development of cellular tissue. Succulent plants are remarkable for the small number of Stomata (q. v.) on the green surface. They are generally found in dry climates, often as almost the only vegetation of the most arid places; although some of them occur in situations where moisture is often abundant; their peculiar structure, however, being apparently intended to adapt them for enduring occasional droughts. Thus, there are not only succulent plants in the Sahara and other deserts, but in Britain, and some of them form a conspicuous feature of the flora of the mountains of Europe—as species of *Sedum*, *Rhodiola rosea*, &c.—where they are found in situations sometimes abounding in moisture, but occasionally parched—on bare rocks, steep slopes with scanty soil, and the like. By the want of stomata and the store of moisture in their own cellular tissue, they are adapted for the endurance of long droughts. Yet they live in great part by nourishment derived from the atmosphere, rather than from the soil; a fact which may easily be proved by suspending a specimen of the Common Yellow Stonecrop (*Sedum acre*) by means of a string, when it will be found to flourish for a considerable time, and sometimes to preserve its vitality as long as those planted in the ground. In dry tropical countries, succulent plants perform in part the same office which lichens and mosses do in colder regions, in preparing the first mould for future vegetation.

SUCHET, Louis-Gabriel, Duke of Albufera, and Marshal of France, was descended from an honorable family, and born at Lyon, 2d March 1770. He volunteered as a private into the cavalry of the Lyon national guard in 1792, and subsequently became attached to the army of Italy. His rare intelligence and brilliant valor, displayed at Lodi, Rivoli, Castiglione, Arcola, and in numerous battles of less note, laid the foundation of his military reputation, and in 1798 he became general of brigade. The able manner in which he, with a force not one-sixth of that of the Austrians, kept Melas in check (1800), preventing the invasion of the south of France, and ultimately capturing 15,000 prisoners, is one of the most brilliant military feats on record. S. also took a distinguished part in the campaigns against Austria (1805) and Prussia (1806), and was subsequently (April 1809) appointed generalissimo of the French army in Aragon, where, for the first time, he appears as holding an independent command. The part of Spain committed to his charge, though inhabited by a people distinguished by their obstinacy and patriotism above all others in Spain, was completely subdued, more, however, through his just and able administration, and the strict discipline which he maintained, than by military talent. The latter quality he was only called upon to exercise against Spanish troops, which he had little difficulty in annihilating. In the first few days of 1812, he conquered Valencia, and obtained in addition to his dignity of Marshal (8th July 1811) that of Duke of Albufera, and the grant of a magnificent domain. The five campaigns which he made in the Peninsula are considered perfect models of the kind of service he had to perform—viz., to rivet the chains of a foreign domination on the necks of a patriotic and high-spirited people. The details have been well given by him in his *Mémoires sur ses Campagnes en Espagne* (Paris, 1829, 1834, 2 vols. with atlas). But the misfortunes of the other French armies in Spain compelled S. gradually to relinquish all his conquests. He was created a peer by Louis XVIII., but took service under his old master after his return from Elba, and was charged with the defence of the south-west frontier.

Deprived of his peerage at the second restoration, he did not return to court till 1819, when it was restored, and he soon rose high in royal favor. He died at the château of Saint-Joseph, near Marseille, 3d January 1826. Napoleon's high opinion of S.'s military talents is recorded by O'Meara and Las Casas, and according to his classification, S. ranked second, Massena being first. —His son and successor in the dukedom of Albufera was a member of the Corps Legislatif, and a supporter of the Napoleonist policy under the Emperor Napoleon III.

SUCKING FISH, a name sometimes given to the Remora (q. v.), and to fishes of the family Discoboli (q. v.), which have a sucker formed by the union of the ventral fins, and are capable of attaching themselves by it to stones or other substances. The best known of the British species, and the only one which is of any value as an article of food, is the Lumpsucker (q. v.). Several other species occur on the British coasts, to which the name SUCKER is generally given, as the CORNISH SUCKER (*Lepidogaster Cornubiensis*), and the UNCTUOUS SUCKER or Sea-snail (*Liparis vulgaris*). They are small fishes, destitute of scales.

SUCKLING, Sir John, one of the brilliant cavalier poets of the court of Charles I., was born at Whitton, in Middlesex, and baptized February 10, 1608—1609. His father, also a knight, held office as a secretary of state, and comptroller of the household, but died in 1627, when the poet was in his 18th year. The latter inherited large estates; and having completed his education at Trinity College, Cambridge, he went abroad, and served for some time in Germany under Gustavus Adolphus. He returned about 1632, and was soon distinguished for his wit, gallantry, and lavish expenditure. To aid the king against the Scots, he raised a troop of 100 horsemen, whom he clad in a rich and gaudy uniform of white and red, with plumes of red feathers in their caps. This loyal corps is said to have cost the poet about £12.000. They rode north; but no sooner had the cavalry come within sight of the Scots army at Dunse, than they turned and fled without aiming a blow! This disgrace gave occasion to numerous lampoons, and to a clever though coarse ballad against S.'s gay horsemen; but in reality they behaved no worse than the rest of the English army. Their loyal commander next joined in a scheme to rescue Strafford from the Tower, and this being discovered, he fled for safety to the continent. He died, while yet in the flower of his life and genius, in 1641 or 1642. Various accounts are given of the circumstances attending his death, but the most painful of these, viz., that he poisoned himself in Paris, is confirmed by family tradition. See the Memoir by the Rev. Alfred Suckling (1836), prefixed to a volume of *Selections from the Works of Sir John Suckling*. He had probably run through his fortune, and dreaded want, as well as despaired of the success of the royal arms.

The works of S. consist of four plays, now utterly forgotten, a prose treatise entitled *An Account of Religion by Reason;* a collection of *Letters*, written in a stiff, artificial style; and a series of miscellaneous poems, beginning with *A Session of the Poets*, published in 1637, which is original in style, and happily descriptive of the author's contemporaries. But the fame of S. rests on his songs and ballads, which are inimitable for their ease, gaiety, and pure poetic diction. His ballad of *The Wedding* is still unsurpassed, and one simile in his description of the bride—

> Her feet beneath her petticoat,
> Like little mice, stole in and out,
> As if they feared the light—

has had the honor of being copied by Herrick and Congreve.

SUCRE. See CHUQUISACA.

SUCTO'RIA, an order of insects, containing only those forming the Linnæan genus *Pulex*. See FLEA.

SUDA'MINA, or MILIARY ERUPTION, is one of the diseases of the skin belonging to the class *vesiculæ*, or *vesicles*. The former name is derived from the fact, that the disorder is always accompanied with profuse sweating; while the latter has reference to the size of the vesicles, which do not exceed those of a millet-seed. The vesicles are most abundant on the neck and trunk, and are sometimes, but not always, attended with itching. They almost always occur in association with febrile disorders, which, however, do not seem in any way modified by these occurrences. The only known condition that favors their production is copious and prolonged sweating. They sometimes appear in health during the summer heat, when strong exercise has induced copious sweating. Pathologically, this disease is of so little importance that it is unnecessary to notice its treatment. It is, however, sometimes useful as a sign in diagnosis, especially in typhus and typhoid fevers.

SUDA'N, or SOUDAN, a vast tract of Central Africa, bounded on the N. by the Sahara; on the W. by Senegambia; on the S. by Upper Guinea, and on the E. by the Nile provinces of Egypt. (The term is sometimes used in a wider sense for the belt south of the Sahara, extending from the Atlantic to the foot of the Abyssinian highlands; including Senegambia as Western S., and Darfur, Sennaar, &c., as Egyptian S.). The Niger (q. v.) waters the western regions. The climate of the west and middle districts resembles that of Senegambia and Guinea; that of Eastern S. is still imperfectly known. Agriculture is pursued with considerable skill; cotton, tobacco, and indigo are abundantly grown; and wheat, rice, maize, Guinea-corn, and millet are among the ordinary crops. Gold-dust, which abounds in the rivers; iron, made from iron-stone, which prevails in all parts of the country; and ivory and feathers, are the principal exports. Of the numerous states into which the country is divided, the following are the chief: Bambara, Masina, Gando, Sókoto, Bornu, Bagirmi, Waday, and

Dar-fur (now annexed to Egypt). Area estimated at 2,250,000 sq. m.; pop. 10 to 80 millions. S. is the peculiar home of the negro race.—S. is also the name of a province of Egypt, which is a continuation eastward of the preceding. It includes Kordofan, Nubia proper, Sennaar, &c., with a pop. of about 10,000,000.

SU'DBURY, a municipal borough of Suffolk, 16 m. S. of Bury St. Edmunds, on the left bank of the Stour, across which a bridge connects the town with the suburb of Ballingdon in Essex. The silk and bunting manufactures are the most important branches of industry. There are also brick works, in which the white clay used is notable for its purity. Malting is carried on. S. was one of the first towns into which the woollen manufacture was introduced by the Flemings. Pop. (1871) 6908; (1881) 6584.

SUDDEN DEATH may be induced by natural or by violent causes, and the detection of the true cause is obviously of very great importance, since the acquittal or conviction of a suspected person may depend upon it. Sudden death may occur naturally from syncope (fainting or swooning), from asphyxia (literally pulselessness), or, more correctly, apnæa (privation of breath), or from coma (insensibility). Syncope, or sudden cessation of the heart's action, may occur, as Dr. C. J. B. Williams points out in his *Principles of Medicine*, in two ways. (1.) By the heart losing its irritability (or becoming paralyzed), so that it ceases to contract; and (2) By its being affected with tonic spasm, in which it remains rigidly contracted, losing its usual alternation of relaxation. Sudden death from asphyxia, or, more correctly, from apnæa, occurs when, from any cause, the entrance of air into the lungs is prevented. It is not so often witnessed as a result of disease as of accident. It is sometimes caused by a spasmodic closure of the chink of the glottis (see LARYNX). Sudden death from coma is liable to occur in apoplexy and injuries of the head.

In all cases of sudden death, there is a strong tendency on the part of the public to suspect poisoning. It is very hard to make them understand that persons may die a natural death suddenly as well as slowly; or conversely, that death may really take place slowly and yet be the result of poison. 'One of the means,' says Dr. Taylor, 'recommended for distinguishing narcotic poisoning from apoplexy or disease of the heart, is the difference in the rapidity with which death takes place. Thus, apoplexy or disease of the heart may prove fatal either instantly or within an hour. The only poisons likely to operate with such fatal rapidity are prussic acid or nicotina. Poisoning by opium is commonly protracted for five or six hours. This poison has never been known to destroy life instantaneously or within a few minutes. Thus, then, it may happen that death will occur with such rapidity as to render it impossible, under the circumstances, to attribute it to narcotic poison.'—*Op. cit.*, p. 145.

In its relations to medicine and medical jurisprudence, the subject of this article has been fully discussed by Herrick and Popp, *Der Plötzliche Tod aus inneren Ursachen*, 1848.

SU'DETENGEBI'RGE, the most important mountain-range of Germany, dividing Prussian Silesia and Lausitz from Bohemia and Moravia, and connecting the Carpathians with the mountains of Franconia. It does not form a continuous chain except in the middle, where it is known under the names of Riesengebirge (q. v.) and Isergebirge; the ends, both towards the north-west and south-east, broadening out into great rugged hilly plateaux, with broken chains and isolated peaks. The S. are composed chiefly of granite, gneiss, mica-schist, and porphyry, with superimposed beds of basalt and coal, and are clothed with pines to a height of between 2000 and 3000 feet. They are rich in minerals, especially in the metals, iron, lead, copper, zinc, tin, cobalt, with some silver and gold. Schneekoppe (Snow-Peak) in the Riesengebirge, about 5000 feet high, is the culminating point in the whole range.—The name S. is applied in a narrower sense to the south-east portion of the range, separating Silesia from Moravia.

S'UDRA is the name of the fourth caste of the Hindus. See CASTE.

SUE, MARIE-JOSEPH-EUGENE, a well-known French novelist, was born at Paris, 10th December 1804. His father, Jean-Joseph Sue, was one of the household physicians of Napoleon and he educated his son for his own profession. At the age of twenty the young man became an army surgeon. In this capacity he served in the French expedition to Spain, under the Duke of Angoulême in 1823. Subsequently he transferred himself to the navy; and in 1828, was present at the battle of Navarino. In 1829 his father died, leaving him a handsome fortune, on the acquisition of which he ceased to practice his profession.

After coquetting a little with art, he betook himself seriously to literature, and very soon, in the department of fiction, he achieved a considerable popularity. His earlier efforts were sea-stories, somewhat after the manner of Cooper, or romances in imitation of Scott; and though in both fields he displayed talent, his true power was scarcely as yet developed. Something of it may, however, be traced in his *Mathilde, ou les Mémoires d'une Jeune Femme* published in 1841; but it was first decisively made manifest in the famous *Mystères de Paris*, which began to appear the year after in the columns of the *Journal des Débats*. The furor of excitement occasioned by this work and its successor, *Le Juif Errant*, which appeared in the *Constitutionnel*, not only in France but elsewhere, has seldom, perhaps, been exceeded; and for both the writer received large sums of money. In 1846, his *Martin, l'Enfant Trouvé* was issued; in 1847—1848 appeared *Les Sept Péchées Capitaux*; and in 1852, he published *Les Mystères du Peuple*, his last work of any importance. Throughout Sue's later works there runs a vein of socialism; and at the revolution of 1848 he allied himself with the extremest sect of the Republicans. On 28th April 1850 he was elected deputy to the Legislative Assembly for the department of the Seine, and was assiduous in his duties as such till the *coup d'état* of December 1852, by which he was driven into exile. He retired to Savoy; and at Annecy he died 3d July 1857.

In the writings of Sue great power is displayed; but it is rather of the unhealthy kind, and depends for much of its effect on vicious sources of interest. His books are read once with a fever-heat of curiosity, and scarcely bear reperusal.

SUE'CA, a town of Spain, in Valencia, and 23 miles south of the city of that name, on the Jucar, about 4 miles from the Mediterranean. Brick and tile works are in operation, and there are several flour and rice mills. Pop. 13,500.

SU'ET is a variety of solid fatty tissue, which accumulates in considerably quantity about the kidneys, and omentum of several domestic animals, especially the ox and sheep. Beef suet is extensively used in cookery, while purified mutton suet under the name of *Sevum Præparatum* occurs in the Pharmacopœia, and is obtained by melting and straining the internal abdominal fat. It consists of a mixture of the ordinary animal fats, with a great preponderance of the most solid of them; viz., stearin, which constitutes about three-fourths of the whole. The pure suet of the Pharmacopœia is 'white, soft, smooth, almost scentless; and is fusible at 103°.' It is used as an ingredient in cerates, plasters, and ointments. Ordinary melted suet is frequently employed in the same manner as lard, to preserve potted meats or fish and similar articles from the action of the air.

SUETO'NIUS, CAIUS TRANQUILLUS, son of Suetonius Lenis, a tribune of the 13th legion under Otho, was born probably a few years after the death of Nero. He is known to us chiefly as a Roman historian and miscellaneous writer, for his merits as which he is highly praised by the Younger Pliny. He was also, it is supposed, a teacher of grammar and rhetoric, and a composer of exercises in pleading; nay, from a letter of Pliny's to him, it may be gathered that he sometimes pleaded causes in person. Pliny procured him the dignity of military tribune, which, by S.'s desire, he got transferred to another. Though childless, S. was, through the same friendly agency, presented by Trajan with the *jus trium liberorum*, which, in that reign, was only to be had by great interest. He was afterwards secretary of the Emperor Adrian, whose favor he had secured. The date of his death is unknown. All his works (among which, as we learn from Suidas, there were several on topics usually treated by grammarians) have been lost, except his *Lives of the Cæsars*, his *Lives of Eminent Grammarians*, and (in part only) his *Lives of Eminent Rhetoricians*. It is by the first of these works that he is most favorably known, replete as it is with information about the Twelve Cæsars, from C. Julius to Domitian, which is to be had nowhere else, and abounding with anecdotes which, while they too often prove the profligacy of his heroes, testify to the impartiality of their chronicler. From a period long before the renaissance to the present, these 'Lives' have always been favorite reading, and have found numerous editors, the best of whom is still Burmann (Amsterdam, 1736), and numerous translators into nearly every European language.

SUE'VI, first mentioned by Cæsar, in whose history (*De Bello Gallico*) the name is employed as the collective designation of a great number of Germanic peoples. They occupied a district of indefinite extent on the eastern side of the Rhine, and may have been the same tribes as those subsequently known as Chatti, Longobardi, &c. Cæsar states that their territory comprised 100 cantons, and was densely wooded, that they had towns (*oppida*), but no strongholds, and that every year a part of the population left their homes to seek employment in war. The S. of whom Tacitus speaks (*Germania*, 38, &c.) seem to have dwelt north and east of the S. of Cæsar, extending as far as the Elbe and the Baltic, which Tacitus calls the 'Suevic Sea.' The peoples united under the rule of Marobodnus, the Marcomannic chief, were Suevic, and hence the Marcomanni and Quadi, who figure in the reigns of Marcus Aurelius and Aurelian, are often called Suevi. After the name had fallen into disuse as a collective designation, it reappeared (second half of the 3d c., *Amm. Marc.*, &c.) as the name of a people occupying the same territory as the S. of Cæsar, who appear, however, to have been a mixed race made up of ad-

venturers from different parts of Germany, and who probably took the name of S. after possessing themselves of the country. We find them in alliance with the Burgundians, Alemanni, Alani, Vandals, &c. They are among the most notable of the barbaric peoples that broke up the Roman Empire in the north-west and west. Bursting through the passes of the Pyrenees (409 A.D.), they, along with the Vandals, overran and wasted Spain q. v.). Those who remained at home in Germany seem to have spread during the 5th c. east to the Neckar and the Rauhe Alps, and south as far as Switzerland. The medieval Swabians were their direct descendants.

SU'EZ, until recently, a small, ill-built, wretched-looking town on an angle of land near the northern extremity of the Gulf of Suez, 76 miles east of Cairo, with which it is connected by railway. The pop. was officially returned, in 1872, as 13,498. It is walled on all sides but that towards the sea, has an indifferent harbor, but a tolerably good quay. S. of late has been greatly improved. English and French houses, offices, and warehouses have been erected in every direction, and the bazaars are assuming a respectable appearance. These bazaars are provided with clarified butter from Sinai, with fowls, grain, and vegetables from the Egyptian province of Sharkijeh, and with wood, dates, and cotton. Rain falls but seldom, sometimes not once in three years. All around stretches a burning waste of sands. S. owes its modern prosperity to the establishment of what is known as the *Overland Route* (q. v.) to India, in consequence of which a large portion of the traffic between England (and other European countries) and the East passes through the place; and to the opening of the Suez Canal in 1869. For a long time previous to the establishment of the overland route, S. had been in a state of complete decay, although, at a yet earlier period—previous, in fact, to the discovery of the sea-route to India by the Cape of Good Hope—it was a flourishing emporium of the products of East and West. A salt manufactory was recently established here by the Egyptian government, and from May to July 1875, six thousand tons of salt were sent to India.

The GULF OF SUEZ is the western and larger of the two branches into which the Red Sea divides towards its northern extremity, and washes on the west the coasts of Egypt, on the east those of the Sinaitic peninsula. Extreme length, 200 miles; average breadth, about 20 miles. The shores are sometimes low, barren, and sandy wastes, sometimes bold and rocky headlands.

The ISTHMUS OF SUEZ is a neck of land 72 miles in width at its narrowest part, extending from the Gulf of Suez on the south to the Mediterranean on the north, and connecting the continents of Asia and Africa. It embraces within its limits (according to the commonly received opinion) the fertile Goshen (q. v.) of antiquity; but it is now a wretched uninhabitable waste, consisting of mingled sand and sandstone, interrupted here and there with salt swamps or lakes, but almost entirely destitute of fresh water. The main interest that attached to this region, in recent times, was, whether or not—since Egypt was on the great highway to India and China—it was practicable to cut a ship-canal through the Isthmus. We shall here briefly indicate the main steps that were taken to have this important question solved in a satisfactory manner.

It is certain that, in ancient times, a canal connecting (indirectly) the two seas did exist. At what period it was constructed is not so certain. Herodotus ascribes its projection and partial execution to Pharaoh Necho (about 600 years B.C.); Aristotle, Strabo, and Pliny less felicitously fix on the half-mythical Sesostris as its originator. The honor of its completion is assigned by some to Darius, king of Persia, by others to the Ptolemies. It began at about a mile and a half from Suez, and was carried in a north-westerly direction, through a remarkable series of natural depressions, to Bubastis, on the Pelusiac or eastern branch of the Nile. Its entire length was 92 miles (of which upwards of 60 were cut by human labor), its width from 108 to 165 feet, and its depth 15 (Pliny says 30) feet. How long it continued to be used, we cannot tell; but at length it became choked up with sand, was restored by Trajan early in the 2d c. A.D., but again became unusable from the same cause, and so remained till the conquest of Egypt by Amrou, the Arab general of the calif Omar, who caused it to be reopened, and named it the 'Canal of the Prince of the Faithful,' under which designation it continued to be employed for upwards of a century, but was finally blocked up by the unconquerable sands, 767 A.D. In this condition it has ever since remained. The attention of Europe was first turned to it in modern times during the invasion of Egypt by Bonaparte, who caused the isthmus to be surveyed by a body of engineers, who arrived at the opinion that the level of the Mediterranean is 30 feet below that of the Red Sea at S., an opinion which a subsequent survey proved to be erroneous.

From this time, the question continued to be agitated at intervals, especially by the French, and various plans were proposed, but nothing definite was arrived at till 1847, when France, England, and Austria sent out a commission to measure accurately the levels of the two seas. The commissioners, M. Talabot, Mr. Robert Stephenson, and Signor Nigrelli, ascertained that, instead of a difference of 30 feet, the two seas have *exactly the same mean level.* The only noticeable difference was, that there is a tide of 6½ feet at the one end and 1½ foot at the other. Another examination leading to similar results was made in 1853. Mr. Stephenson expressed himself very strongly against the feasibility of a canal, that is to say, a canal of such dimensions as would suit the requirements of modern commerce, and planned, instead, a railway from Cairo to S., which was opened (1858), and which now conveys overland all our Indian and Australian mails. The French, however, were not satisfied with Mr. Stephenson's conclusions, and M. Talabot, on his return to Europe, published in the *Revue des Deux Mondes* a plan for connecting the two seas by way of Alexandria and S. (or rather a point 6 miles below S.), for a description of which we have not space. In 1854, a new experimenter appeared in the person of M. de Lesseps, a member of the French diplomatic service in Egypt, who (1856) obtained from the pasha the 'concession,' i. e., the exclusive privilege of forming a ship-canal from Tyneh (near the ruins of ancient Pelusium) to Suez. The peculiarity of M. de Lesseps's plan lay in this, that, instead of following an oblique course, and uniting his canal with the Nile, as the ancients had done, and as all the modern engineers had thought of doing, he proposed to cut a canal right through the isthmus in a straight line to Suez.

This canal was to have a minimum width at the surface of 262 feet, and at the bottom of 144 feet, with a depth of 22½ feet; and

Map showing Suez Canal.

at each end there was to be sluice-lock formed, 330 feet long by 70 wide. By taking advantage of the tides at S., it was hoped that an additional depth of 3 or 4 feet might be obtained. But the colossal feature of M. de Lesseps's plan was the artificial harbors which he proposed to execute at the two ends. That at the Mediterrean end was to be carried out 5 miles; that at S., 3 miles. The English looked with aversion on M. de Lesseps's scheme; but in 1855, a new European commission was appointed, which reported that M. de Lesseps's scheme, somewhat modified, *was practicable.* The result of the report was the formation of a joint stock company, with a subscribed capital of £8,000,000 (afterwards increased) in which Saïd, the Pasha of Egypt, took a large number of shares, and made large concessions of land; and the work was accordingly begun. The canal was to be dredged through Lake Menzaleh, which runs far into the land directly towards S., to be connected with Lake Temsah, the Bitter Lake, and other marshy swamps, and so with Suez. Only a third of the way required to

be excavated through the sands and rocks of the desert. Work was begun in the end of 1860. In April, 1865, the works, at the request of M. de Lesseps, were visited by another scientific commission, who reported favorably of the scheme.

The canal was formally opened in November 1869.

The hostility of the British nation to the canal faded away with its successful completion and the advantages which it afforded to British commerce; and in 1875, the British government purchased, for £4,000,000, the Khedive of Egypt's shares in the canal, which amounted to 176,602 out of 400,000. These shares give no returns to their owner till 1894, the Khedive having alienated the dividends till that period in favor of the company. The fears expressed at the opening of the canal, that the trade of the East would be diverted from Great Britain as a center, were soon found by statistics to be groundless. In fact, the great proportion of the shipping that passes through the canal—usually about four-fifths of the whole—is English. Thus, in 1882, 3198 ships, of 7,122,156 tons, passed through; of these, 2565 ships, of 5,795,598 tons, were British. The revenue grew from £915,839 in 1873, to £2,421,835 in 1883. The clear profit in the latter year amounted to more than half of the gross income: less than half sufficing to cover the expenditure. The heavy dues (ten shillings a ton) and the enormous profit created much dissatisfaction amongst British shipowners; as well as the fact, that while M. de Lesseps commanded 21 votes at the Board of Management, Britain has only 3 votes. Accordingly, the scheme of a second canal, diverging more or less widely from the route of the present canal, was ventilated. A project negotiated between M. de Lesseps and the British government in 1883, gave so large concessions in favor of M. de Lesseps and the existing company, that it was highly unpopular in Britain, and had to be withdrawn. Plans for widening the old canal, and for providing large basins, in which ships going opposite ways may pass one another, were in progress in 1883.

SUEZ CANAL. In the above article on this subject, the nature of the scheme has been briefly described, and illustrated by a small map; and the progress of the works noticed down to the year 1865. In this place, some of the features will receive a little further explanation. The canal is 100 miles long, 25 of this length being through lakes.

The Port Said Entrance.—Port Said or Saïd, a town now containing 10,000 inhabitants, had no existence in 1860. It became the dépôt of the Company, the metropolis of vast bodies of laborers and other persons employed on the works of the canal. As the Mediterranean Sea is very shallow near this point, an artificial deep channel had to be made, bounded east and west by piers stretching far out into the sea. Stone for these piers was, in the first instance, brought from a long distance; but afterwards artificial stone was made on the spot, consisting of two parts of sand and one part of hydraulic lime ground into a paste, and poured into wooden boxes or moulds. When the mixture solidified, the mould-boards were removed, and the solid blocks of artificial stone were left from three to six months in the open air to dry and harden. The blocks contain 10 cubic mètres each, weigh 20 tons, and were made at a contract price of 42 francs per *mètre cube*. The western pier has a length of 7000 feet, and the eastern of 6000 feet: they are 4600 feet apart at the shore, but gradually approach towards each other, so that their outer ends are only 2300 feet apart. The western pier is continued in an arc of 1100 yards extent, so as, with the eastern pier, to shelter the harbor from all winds. Within this outer harbor is an inner port, 870 yards by 500, which is kept at a uniform depth of 30 feet, by means of steam-dredging. The lighthouse, with its electric light, is 180 feet high.

From Port Said to Temsah Lake.—From Port Said, the canal crosses about 20 miles of Menzaleh Lake, a salt-water shallow, closely resembling the lagoons of Venice, having from 1 to 10 feet depth of water. The canal through this lagoon is 112 yards wide at the surface, 26 yards at the bottom, and 26 feet deep. An artificial bank rises 15 feet on each side of this channel. Beyond Menzaleh Lake, heavier works begin. The distance thence to Abu Ballah Lake is 11 miles, with a height of ground above the level of the sea varying from 15 to 30 feet. Crossing the last-named lake, there is another land distance of 11 miles to Temsah Lake, cutting through ground to a depth varying from 30 to 70 or 80 feet; and then 3 miles further across this little lake itself. At El Guisr, or Girsch, occurs the deepest cutting in the whole line, no less that 85 feet below the surface; at the water-level it is 112 yards wide, at the summit-level 173 yards, from which the vastness of the gap may be estimated. Ismailia (pop. 5000) on Temsah Lake, is regarded as the central point of the canal. While the canal was being made, it grew up rapidly from an Arab village to a French town, with the houses of engineers and managers, hotels, shops, cafés, a theater, and a central railway-station, from which railways stretch to Alexandria and Suez.

The Fresh-water Canal.—This extends from the Nile Temsah Lake, and was constructed purposely to supply with water the population accumulating at various points on the line of the canal; but it is also used by small sailing-vessels. This fresh-water or 'sweet-water' canal comprises three portions or sections: (1) from the Nile east or north-east to Ismailia, on Temsah Lake; (2) from Ismailia, nearly south to Suez, on the western side of the great ship or maritime canal; (3) from Ismailia nearly north to Port Said, also on the west side of the ship canal. The first and second of these sections are really canals, large enough to accommodate small steamer and barge traffic; but the third section consists simply of a large iron pipe, through which the water is conveyed to the several stations. Plugs are inserted in the pipe wherever needed, to allow water to be drawn off for everyday wants.

From Temsah Lake to Suez.—The route crosses Temsah Lake to Toussoum and the Serapeum cutting, through a plateau 46 feet above the sea, where the waters were let in by the Prince and Princess of Wales, February 28, 1869. There is a space of 8 miles from Temsah Lake to the commencement of the Bitter Lakes, which had to be dug to a depth varying from 30 to 62 feet, according to the undulations of the surface. In these deep cuttings, owing to the great width of the canal, the quantity of sand to be dug out (for it is nearly all sand, though sometimes agglomerated with clay) was enormous, requiring the constant labor of a large number of powerful dredging machines and elevators. In passing through the Bitter Lakes, there was more embanking than excavating to be done, seeing that the bottom of this region is only two or three yards above the intended bottom of the great canal. From the southern end of the Bitter Lakes to Suez, a distance of about 13 miles, there is another series of heavy cuttings through the stony plateau of Chalouf, varying from 30 to 56 feet in depth. Where cutting is thus difficult, the surface width is reduced considerably from the regular width of 327 feet. The canal is intended throughout to be 72 feet wide at the bottom, and 26 feet deep.

On November 16, 1869, the S. C. was opened in form, with a procession of English and foreign steamers, in presence of the Khedive, the Empress of the French, the Emperor of Austria, the Crown-Prince of Prussia, and others. On November 27, the *Brazilian* went through; a ship of 1809 tons, 380 feet long, 30 feet broad, and drawing from 17½ to 20½ feet of water. Since then the canal has continued in successful operation, and passages have been made almost daily, chiefly by British vessels. The cost of construction of the canal was said to have reached, in December 1869, the total of £11,627,000. In 1870, 491 ships, of 436,618 tons, passed through; and in 1874, 1264 ships, of 2,424,000 tons. About 70 per cent. of the shipping and tonnage belongs to Great Britain. The great advantage of the canal is, of course, the shortening of the distance between Europe and India. From London or Hamburg to Bombay is by the Cape about 11,220 miles, but by Suez only 6332—that is, the voyage is shortened by 24 days. From Marseille or Genoa there is a saving of 30 days; from Triest, of 37. The rate at which steamers are allowed to pass through, is from 5 to 6 knots an hour. The canal charges are, 10 francs per ton, and 10 francs per head for passengers. The receipts for 1873 amounted to 22,755,862 francs, or £911,032; for 1875 (when 1494 ships passed through), to £1,155,185; for 1876 (1457 ships passed), £1,245,750. In 1880, 2011 ships passed.

SUFFOCA'TION. See ASPHYXIA and RESPIRATION.

SU'FFOLK, a maritime county of England, bounded on the N. by Norfolk, and on the S. by Essex. Area, 947,681 acres; pop. (1861) 337,070; (1871) 348,475; (1881) 356,863. The surface is for the most part flat, falling away into marshes on the north-west and north-east borders. The coast-line, which is low and marshy, or lined with cliffs of shingle or gravel and red loam, is about 50 miles in length, and is, on the whole, regular, being unbroken by any considerable indentation, and comprising no headland worthy of notice except Lowestoft Ness, the most easterly point in Great Britain. The tributaries of the Waveney, which separates S. from Norfolk on the north, and those of the Stour which forms the boundary-line on the south, together with the river Lark, an affluent of the Great Ouse, and the Gipping, which, after it begins to broaden into an estuary, is called the Orwell, are the chief streams. The climate is cold in spring, but is drier than that of the western counties. The soil is of various kinds, some of which are very productive. 770,000 acres are under cultivation, and the most improved system of agriculture has been introduced, together with the best and newest agricultural implements. A polled breed of cattle, of which the cows are deservedly held in high esteem, is peculiar to the county. The S. pigs are a famous and most profitable breed. There are in the county about 430,000 head of sheep, chiefly Southdowns and crosses of this breed. The ordinary crops are raised. The county sends four members to parliament. Capital, Bury St. Edmunds.

SU'FFRAGAN (Lat. *suffraganeus*, from *suffragium*, a suffrage or vote), the name given to a bishop in a province, in his relation of dependence or subordination to the archbishop, or rather met-

ropolitan, of the province. See METROPOLITAN. In some continental churches, the name is applied to coadjutor-bishops appointed—as in the case of prince-bishops in the German Empire—to assist the bishop in his own diocese.

SU'FFRAGE (Lat. *suffragium*, derivation uncertain), a right to vote, and more particularly the right possessed by the citizen of a state where representative government exists, to vote for a member of the legislative body.

The idea that the universal enjoyment of political suffrage is a right by natural law, is grounded on the fiction, that the obligations of municipal law arise out of a social contract express or implied. In opposition to this notion, it is argued that the true purpose for which government exists is the general welfare of the nation; and it is the duty of the state to consider whether the suffrage may be more beneficially exercised by the many or the few. Infants, minors, idiots, and insane persons have everywhere been excluded from the suffrage, on the ground that sound judgment is necessary for its exercise. Persons convicted of crimes have been excluded, as a security to society; and also almost universally women, for reasons based on their relation to society and to the opposite sex. Like considerations of expediency, it is argued, are a ground for withholding the suffrage from those whose circumstances and station in life render it unlikely that they should form a sound judgment on political questions. It is the intelligence and enlightenment of the country that an elective legislature should represent; and in any large extension of the suffrage, there is obviously a risk of the intelligence of a constituency being swamped by its mere numerical majority. A widely extended suffrage has, however, been advocated as a valuable means of educating the people to self-dependence; and several philosophical politicians of the present day, who are favorable to a large extension of the electoral qualification, propose to obviate what they regard as its otherwise inevitable evils, by graduating the suffrage, so as to give each individual elector a number of votes corresponding as much as possible to his property, education, or social position. Schemes for this end, differing in detail, have been proposed by Mr. J. Stuart Mill, in his *Considerations on Representative Government* (1861); and by Professor Lorimer in his *Political Progress not necessarily Democratic* (1857), and *Constitutionalism of the Future* (1865). See REFORM, REPRESENTATION, BALLOT.

SU'FISM (from *sufi* or *sofi*, the Greek *sophos*, a sage; erroneously also derived from Arab. *sof* or *suf*, wool, and thus designating an individual who wears nothing but woollen garments) designates a certain mystic system of philosophical theology within Islam. Its devotees form a kind of ecclesiastical order somewhat similar to that of the Fakirs (q. v.), or dervishes, but they are mostly of a far superior stamp; and some of the greatest Persian poets, philosophers, historians, and even kings belonged to their ranks. They assume four principal degrees of human perfection or sanctity. The first or lowest is that of the Shariat—i. e., of the strict obedience to all the ritual laws of Mohammedanism, such as prayer, fasting, pilgrimage, almsgiving, ablutions, &c., and the ethical precepts of honesty, love of truth, and the like. The second degree (Tarikat) is not attainable by all, but only by those higher minds that, while strictly adhering to the outward or ceremonial injunctions of religion, rise to an inward perception of the mental power and virtue necessary for the nearer approach to the divinity, the necessity of, and the yearning for, which they feel. The third (Hakikal = truth) is the degree of those who, by continuous contemplation and inner devotion, have risen to the true perception of the nature of the visible and the invisible—who, in fact, have recognized the Godhead, and through this knowledge of it have succeeded in establishing an ecstatic relation to it. This state is finally sublimated into that highest and last degree (Maarifal), in which man communicates directly with the Deity. Practically, the great mass of the people take the lowest degree; the second stage is reached by the 'Murides,' who do not fulfil the behests of the ceremonial law because they are behests, but because they are good in themselves, knowing that virtue is good; and because it leads to truth, they adhere to it for its own sake. They give alms because the sight of poverty grieves them; their ablutions are as much due to their desire of physical purity as to that of obeying a religious injunction.

The third stage is that of the Naibs, to whom all this spiritualizing of faith applies in a still more eminent degree. And the highest stage of attainable perfection is that of the Murshid, whose words are God's words, pure and simple, because he is in direct and constant communion with God. He is the 'Sun of faith,' by whose reflected light shine the Naibs, its 'moons.' All Sufistic poetry and parlance is to be taken allegorically and symbolically. They represent the highest things by human emblems and human passions; and religion being with them identical with love, erotic terminology is chiefly used to illustrate the relation of man to God. Thus the beloved one's curls indicate the mysteries of the Deity; sensuous pleasures, and chiefly intoxication, indicate the highest degree of divine love as ecstatic contemplation; while the wine-house, of which constant mention is made, merely indicates the state in consequence of which our human qualities merge in or are exalted into those of the Deity. Founded in the 9th c. by Kafi-Mullah, this peculiar mysticism has principally struck root in Persia, and chiefly among men of genius, e. g., Hafiz (q. v.). Recently, it has been revived, with slight modifications, by Shamil the renowned and once formidable antagonist of the Russians, who undertook to enlist even the common soldiers, if not in the ranks of the initiated—for Sufism, in its real meaning, is very exclusive—at least of its votaries; and the very lowest among them even had a sentence given him indicative of his forming part of the sect and of the gradations that form its main characteristic. In conclusion, it may be observed that Sufism mixes up all religions and all their prophets indiscriminately in one class; and the words idolatry, unbelief, licentiousness, and the like are generally used in their reverse sense by its votaries. Their principal religious writer is Jalaleddin Rumi.

SUGAR (Lat. and Gr. *sacchar-*, Sans. *sarkara*, Pers. *schakar*, Arab. *sokkar* or *assokkar*, Sp. *azucar*, It. *zucchero*, Fr. *sucre*, Ger. *zucker*) is a general term applied by chemists to a number of neutral carbo-hydrates, possessing a more or less sweet taste, for the most part crystallizable, and produced by the vital processes going on in certain plants and animals. They are divisible into two groups, the first embracing such sugars as are capable of undergoing fermentation, and of being resolved, under the action of yeast, either directly or indirectly into alcohol and carbonic acid gas; and the second including those sugars which are not capable of being broken up by fermentation into the above-named products. The first group contains cane-sugar or sucrose, fructose or inverted sugar, trehalose, mycose, melezitose, melitose, grape-sugar or Glucose (q. v.), and milk-sugar or lactose; while the second group includes inosite or inosin, sorbite or sorbin, and scyllite or scyllin.

Cane-sugar or *sucrose* ($C_{12}H_{11}O_{11}$), the ordinary sugar of commerce, is by far the most important of this class of compounds; and in so far as its sweetening properties are concerned, it exceeds grape-sugar in the ratio of 5 to 2, and milk-sugar in a still higher ratio. It has a specific gravity of 1·6. It dissolves in about one-third of its own weight of cold water, producing a thick viscid syrup, and in all proportions in hot water; it is slightly soluble in absolute alcohol, but spirit of wine of specific gravity 0·830 dissolves about one-fourth of its weight. By the spontaneous evaporation of its watery solution, it is deposited in four-sided rhomboidal prisms. Common loaf-sugar and sugar-candy are two well-known forms of crystallized sugar; the former consisting of a mass of small transparent crystals, and owing its dazzling whiteness to the numerous reflections and refractions which the rays of light undergo within the interior from the numberless crystals of which it is composed; while the brown color which the latter usually possesses is due to the coloring matter not having been removed from the syrup previous to crystallization.

The crystals of sugar-candy are larger than those of loaf-sugar, in consequence of the slower evaporation in the former case. When crystals of sugar—as, for example, two pieces of loaf-sugar—are rubbed together in the dark, a pale phosphorescent light is evolved. If a solution of sugar be boiled for a long time, it acquires an acid reaction, and loses its power of crystallizing—a change which is attended by the assimilation of additional water, and the formation of the uncrystallizable inverted sugar, which will be presently described. If the boiling be further prolonged, the inverted sugar ($C_{12}H_{12}O_{12}$) assimilates more water, and is converted into grape-sugar ($C_{12}H_{12}O_{12} + 2Aq$), while a little formic acid and ulmin (a brown, nearly insoluble substance belonging to the *humus* group) are produced. The crystallization of sugar is also prevented by the addition of a little oxalic, citric, malic, or any of the stronger acids to its solution; and in order to check the bad effects of an acid, a small quantity of lime is usually added to the cane-juice before it is heated.

The action of different degrees of heat on sugar has been carefully studied. At about 320°, sucrose fuses, and on cooling, forms the transparent amber-colored solid known as *barley-sugar*, which, if kept for a long time, assumes a crystalline state, and becomes opaque. If the application of heat be continued until about 400°, the sugar loses two atoms of water, and *caramel*, which is described in the article GLUCOSE, is formed, and at a still higher temperature, the changes which sucrose undergoes are identical with those suffered by glucose. Sugar dissolves many metallic oxides when its solution is boiled with them—as, for example, freshly precipitated oxide of lead, lime, and baryta, and its presence prevents the precipitation of alkalies of various metallic oxides from their salts—the oxides of copper and of iron being thus retained in solution. Many metallic oxides are partially or entirely reduced when boiled with sugar; thus, chromic

acid is reduced to sesquioxide of chromium, salts of the red oxide of mercury are converted into those of the suboxide, and salts of gold give a precipitate of the reduced metal. It does not reduce alkaline solutions of oxide of copper to the suboxide (Trommer's test) unless with the aid of heat, which converts it into glucose. Under the action of certain oxidizing agents, it may be converted into propionic, formic, and acetic acids. Sucrose is not *directly* capable of undergoing fermentation; but in the presence of a ferment (yeast, for example) it is converted into glucose, and in that form it readily undergoes vinous, lactic, and butyric fermentation. Its action on polarized light is described below.

This variety of sugar is chiefly obtained from the juice of the sugar-cane, but it is also abundantly present in the juices of certain species of maple and of beet-root, all of which yield this substance as a commercial product; it is also contained in Sugar-grass (*Sarghum saccharatum*), whose juice yields 13 per cent. of sugar; in carrots and turnips, in the pumpkin, the chestnut, the young shoots of maize, in the flowering buds of the Cocos palm, and in a large number of tropical fruits. Its use as an article of diet has been already mentioned under DIET. Several articles of food contain some form of sugar in considerable quantity. In peas, there are 2 per cent. of sugar; in rye-meal and wheaten bread, about 3½ per cent.; in cows' milk, 4½ per cent.; in goats' milk and in barley-meal, 5½ per cent.; in human milk, in asses's milk, ripe gooseberries, and ripe pears, about 6 per cent; in oatmeal, about 8 per cent; in wheaten flour, from 4 to 8 per cent.; in beet-root, from 5 to 10 per cent; in ripe peaches, 16½ per cent.; in ripe cherries, 18 per cent; and in dried figs upwards of 60 per cent. Although sugar is commonly regarded as a luxury, it is in reality a very valuable article of food (as, indeed, might be inferred from its presence in milk, and in both the yelk and white of eggs), since it is very rapidly digested, and supplies heat-forming or respiratory food to the system. 'When, however,' says Dr. E. Smith, 'it is compared with wheaten flour, it is a very dear food, since three or four times more carbon will be obtained for 1*d.* in flour, besides nitrogen, none of which is found in sugar. It has also been proved by Messrs. Lawes and Gilbert that even its fattening properties—that is to say, its power to form fat in the system, when it is supplied in excess of the quantity which the daily wants of the body require to produce heat—are not greater than those of starch as found in the cheapest grain.'—*Practical Dietary*, 1863, p. 63.

In consequence of sugar being a fat-forming substance, it should be taken very sparingly in cases of excessive obesity. There are certain forms of dyspepsia in which sugar should be avoided, as exciting increased gastric uneasiness; and in diabetes, all articles of food containing or (like starch) yielding sugar, should be rigidly prohibited. Although prone to fermentation when in a dilute state, in its concentrated form sugar possesses great antiseptic power, and is extensively employed to preserve both vegetable and animal substances from decay. The sugar naturally existing in some fruits is often sufficient to insure their preservation in a dry state, while in other cases it is added, as in preserves and jellies. A mixture of salt and sugar applied to meat, fish, &c., preserves more of the natural flavor than mere salting does. Sugar converted into caramel is much used by cooks and confectioners as a coloring matter.

Closely allied in their chemical characters to sucrose are the following comparatively rare forms of sugar: (1) *Trehalose* ($C_{12}H_{11}O_{11} + 2Aq$), so called from *Trehala*, or Turkish Manna (the product of a coleopterous insect, *Larinus nidificans*), from which this variety of sugar is extracted, differs from sucrose in the following points—it crystallizes in brilliant rectangular octahedra; contains water of crystallization; fuses at 212°, and loses its water of crystallization; is very soluble in hot alcohol; possesses about three times as great a rotatory power on polarized light; and when heated to 356° does not undergo further change. (2) *Mycose*, obtained from ergot of rye, possesses the same composition as trehalose, from which it mainly differs in crystallizing in rhombic prisms, and in exhibiting a somewhat weaker rotatory power. (3) *Melezitose* ($C_{12}H_{11}O_{11}$), obtained from larch manna, differs from cane-sugar in its less sweet taste, and in exhibiting a less powerful rotatory action. (4) *Melitose* ($C_{12}H_{12}O_{12} + 2Aq$), the chief ingredient in the Australian manna yielded by the *Eucalyptus* tree, crystallizes in acicular prisms, is feebly sweet, undergoes fermentation with yeast, but yields only half as much alcohol and carbonic acid as would be obtained from an equal weight of glucose, one half of this sugar being converted into an unfermentable syrupy body, known as *Eucalyn* ($C_{12}H_{12}O_{12}$).

More important than any of the above varieties, and differing from cane-sugar in a distinctive physical property, is the substance formerly known as *Fruit Sugar*, but now often described as *Inverted Cane-sugar*. The objection to the former name is, that the sugar contained in many ripe acidulous fruits, and formerly regarded as a distinct variety, is merely a mixture of cane-sugar, with more or less of the *Inverted Sugar* ($C_{12}H_{12}O_{12}$), which has already been noticed as resulting from the action of prolonged boiling, or of a little acid on cane-sugar. The same change occurs in many ripening fruits, in consequence of the presence of a peculiar albuminous ferment. Inverted sugar is not crystallizable, is soluble in dilute alcohol, and produces *left*-handed rotation; hence its name. By chemical means, it is convertible into grape-sugar, a change which sometimes occurs spontaneously, as is seen in the gradual crystallization of the sugar in dried fruits.

Grape-sugar, constituting the hard granular sweet masses occurring in old dried fruits, such as rasins, figs, &c., has already been described in the article GLUCOSE, or GLYCOSE, under which names it is commonly known to chemists. It is also known as *Starch-sugar*, because it is readily obtained by the action of a dilute acid on a hot solution of starch, and is identical with the sugar occurring in the urine in diabetes.

Milk-sugar, known also as *Latine* and *Lactose* ($C_{20}H_{19}O_{19} + 5Aq$, or, according to some chemists, $C_{12}H_{11}O_{11} + Aq$), is a purely animal product. It exists in considerable quantities in the milk, especially of the herbivorous animals, and is one of the most important and essential ingredients in that secretion. It may be obtained on a large scale by separating the curd from the milk, and evaporating the whey till it is ready to crystallize; when, on the introduction of small pieces of wood, the crystals of sugar are deposited on them.

These crystals are four-sided prisms of a milk-white color, and so hard that they crunch between the teeth. This variety of sugar is only moderately sweet (*vide supra*), requires about six times its weight of cold water for its solution, but dissolves readily in boiling water, while it is insoluble in alcohol or ether. If it be gradually heated to 284°, two equivalents of water are expelled, whereas, if it be suddenly heated to about 400°, all five equivalents are given off. When pure, milk-sugar is insusceptible of fermentation; but when boiled with dilute acids, it is converted into a directly fermentable sugar, in many respects very similar to grape-sugar, and to which some chemists have given the name of *Lactose*, a term commonly applied to milk-sugar itself. On treating a moderately diluted acid solution of milk-sugar with yeast, this variety is first formed, and then yields carbonic acid and alcohol; if, however, decomposing matters, as, for example, casein in the act of disintegration, are present, it undergoes lactic and butyric fermentation; and hence we understand how milk after exposure for a time to the air becomes sour. The intoxicating character of the drink prepared by the Kalmucks and Tartars from sour mares' milk, is due to this indirect vinous fermentation of sugar of milk. Regarding the uses of this variety of sugar, it may be observed that it is probably the most important of the constituents of whey (which is milk deprived of the whole of its casein except a mere trace held in solution), and hence that it is the active ingredient in the *whey-cure*, which is so popular in Switzerland. (The whey in these cases is usually obtained from goats' milk). It is also the chief constituent of the globules used in homœopathy.

The second group of sugars, namely, those which are incapable either directly or indirectly of undergoing fermentation, are of less practical importance than cane-sugar, grape-sugar, or milk-sugar.

Inosin, or *Inosite* (derived from the Greek *is*, gen. *inos*, muscle), is represented by the formula $C_{12}H_{12}O_{12}+4Aq$. It occurs as a normal constituent in the juice of the heart, and of the involuntary or unstriped muscles, and has also been found in the tissues of the lungs, spleen, liver, kidneys, and brain, and in the urine in Bright's disease and diabetes. It has been recently shown that it is identical with the substance previously known as *Phaseo-mannite*, which is readily obtained from the unripe seeds of the common kidney-bean (*Phaseolus vulgaris*). It forms colorless efflorescent prisms, which lose four equivalents of water at about 210°. When mixed with decaying cheese and chalk, it becomes gradually converted into lactic and butyric acids. *Scyllite* is a saccharine matter closely resembling inosite, and occurring in various organs of several plagiostomous fishes, and especially in the kidneys of the rays and skate. It differs, however, from inosite in its crystalline form, and in its containing no water of crystallization. Its composition is unknown. *Sorbin*, or *Sorbite* ($C_{12}H_{12}O_{12}$), derives its name from its occurring in the juice of the berries of *Sorbus aucuparia*, the Service Tree, and may be obtained in colorless transparent rhombic octahedra. It reduces oxide of copper to the suboxide (Trommer's test), and is of a sweetish taste.

Closely allied to the sugars, but differing from them in their chemical composition (inasmuch as they do not contain hydrogen and oxygen in the proportions to form water), are *Mannite* ($C_{12}H_{14}O_{12}$), obtained from *Manna*, the inspissated juice of the *Fraxinus ornus*, but also occurring in celery, onions, asparagus shoots, *Laminaria saccharata* and other sea-weeds, certain fungi, the juice which exudes from apple and pear trees; *Dulcite* ($C_{12}H_{14}O_{12}$), the product of an unknown Madagascar tree; *Quercite* ($C_{12}H_{12}O_{10}$), obtained from acorns; and *Pinite* ($C_{12}H_{12}O_{10}$), from *Pinus lambertiana*, a tree growing in Australia and California. All these bodies are crystalline, and sweet to the taste.

Although chemists have hitherto looked upon the sugars as or-

ganic compounds, without any recognizable radical, and from their composition have termed them *carbo-hydrates*, 'the researches of Berthelot render it propable that the sugars as well as mannite, and the bodies allied to it, are polyatomic alcohols, like glycerine, for he has found that they possess the power of entering into combination with various acids, with elimination of water, in some cases yielding colligated acids analogous to the tannic, and in others furnishing neutral bodies closely allied to the fats.'—Miller's *Organic Chemistry*, 2d ed. p. 72.

Amongst the various chemical purposes to which the phenomenon of circular polarization may be applied, we may especially mention its use in determining the quantity of any kind of sugar in solution. While some sugars give a right-handed rotation, others give a left-handed rotation, and each sugar exerts a definite amount of rotatory power. The following are the rotatory powers of the chief varieties of sugar, equal weights of each being dissolved in an equal bulk of water, and the temperature being 56°:

Cane-sugar	$(C_{12}H_{11}O_{11})$,	right	73°·8
Trehalose	$(C_{12}H_{11}O_{11})$,	"	220°
Melezitose	$(C_{12}H_{11}O_{11})$,	"	94°·1
Mycose	$(C_{12}H_{11}O_{11})$,	"	193°
Inverted Sugar	$(C_{12}H_{12}O_{12})$,	left	28°
Grape-sugar	$(C_{12}H_{12}O_{12})$,	right	57°·4
Milk-sugar	$(C_{12}H_{12}O_{12})$,	"	56°·4
Sorbin	$(C_{12}H_{12}O_{12})$,	left	46° 9

This method has been applied to determine the amount of sugar in diabetic urine, to ascertain the quantity of sugar which remains in the unfermented state in wines, and to other similar purposes. As, however, the process is one of extreme delicacy, the method must be used with great caution.

On the production and manufacture of sugar, see *Sugar Growing and Refining*, by Lock, Wigner, and Harland (Spon. 1882); *Sugar Refining*, by Gill; *Sugar Analysis* by Tucker (Philadelphia, 1882).

Manufacture.—The manufacture of sugar from the sugar-cane and other sources is now one of the largest branches of human industry, but this great development is of comparatively recent date; and although there are evidences of its very high antiquity in India and China, sugar appears only to have been vaguely known to the Greeks and Romans. It is mentioned by Theophrastus as 'honey in reeds;' and Lucan has the following line, which indicates a knowledge of its existence, but merely as a curious fact:

'Quique bibunt tenera dulces ab arundine succos.'

Its introduction to Europe appears to have been one of the results of the Crusades. The sugar-cane was grown in Cyprus about the middle of the 12th c.; it was from thence, at a later time, transplanted to Madeira, and at the commencement of the 16th c., was carried from the latter island to the West Indies. Originally, in all probability, only the sweet recent juice was known; for apparently the art of boiling it down, and forming it into raw sugar, was an invention of the 15th c.; and it was not until the middle of the following century that a Venetian discovered the art of refining sugar, which soon became established in Germany. The first refinery of which any notice exists was one in Dresden, as early as 1597; but long previous to this the subject had attracted so much attention as to be discussed in learned treatises, one of which in particular, the *Saccharologia* of Sala, in the beginning of the 16th c., shows that the clarification of the syrup by defecation was then a matter of some importance. Still the manufacture of sugar in the countries to which it had been introduced made but slow progress, for its use was limited by its dearness to the wealthy. The material has now, however, become one of the commonest necessaries of life, and has largely conduced to the health of nations. Until 1747, sugar was supposed to be the product of the sugar-cane only, but in that year, Marggraf, a German chemist, demonstrated that it was a natural product of other vegetables, and especially of the beet-root; and half a century later, its manufacture from that source was first commenced in Silesia. A large portion of the sugar consumed on the continent is now obtained from this source. See BEET-ROOT SUGAR.

Since we have become better acquainted with the sources of our own supplies, we have learned that a large portion of the raw sugar of the East Indies received in British ports as cane-sugar is in reality made from the juice of several palms, especially that of *Arenga saccharifera*, and the wild date, *Phœnix sylvestris*. The juice is obtained from these plants by cutting off the male spadix when young, and from the cut portion there is for four or five months a continual flow. The liquid is at first clear, and is immediately boiled down to a thick syrup, which granulates on cooling, and constitutes, if not otherwise purified, the coarse brown sugar called jaggery, which is extensively consumed in India. More carefully prepared, it is sent to Europe with sugar made in the cane-plantations, and is only distinguished from it by well-skilled persons. If the juice is not immediately boiled, it becomes turbid, and passing into the vinous fermentation, forms the intoxicating drink called toddy.

In Canada and in the United States very much sugar is made by boiling the juice or sap of the Sugar Maple-tree (*Acer saccharinum*). The *Sorghum saccharatum*, or Sugar-grass (See DURRA), and the stalks of ordinary maize or Indian corn (*Zea*) yield sugar, which has lately been made so as fairly to rival the best crystallized cane sugar (see under SUGAR-CANE).

Beet-root sugar is manufactured from the fresh-dug roots, chiefly of the varieties we call Mangold-wurzel. The process (which, however, is constantly undergoing modifications) is briefly described in the article BEET-ROOT SUGAR. Beet-root yields from 7 to 8 per cent. of sugar, of which only 3 to 4 per cent. are of the best quality, called *Melis*, 2 to 3 per cent. of the second quality, called *Farin*, and the remainder molasses.

The manufacture of starch-sugar is described in the article GLUCOSE.

From the beginning of the 16th c., when the sugar-cane of India was introduced to the West Indies, sugar has been one of the most important products of those islands. Careful cultivation has produced many varieties of this useful plant, some of which are better adapted than others for particular localities. The original variety introduced into the West Indies is still cultivated under the name of the *Creole Cane;* but the favorite variety is the *Otaheite Cane*, which is the most luxuriant grower, and gives the largest yield of juice. It is the variety chiefly cultivated in Brazil, Demerara, and Venezuela, as well as the West Indies. In many parts of the East, another admirable variety is the *Batavian* or *Striped Cane;* it was originally raised in Java, and is the favorite with rum-distillers.

The extraction of juice from the sugar-cane is effected by simple pressure. In its native country, India, there are still in use in some districts machines of the rudest construction, which are probably the same which were used a thousand years since. The Chinapatam Sugar-mill (fig. 1) consists of a mortar made by cut-

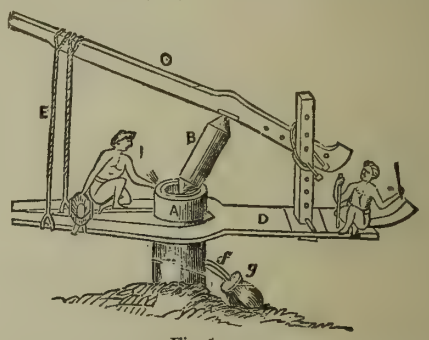


Fig. 1.

ting down some hard-wood tree to within 2 or 3 feet of the ground, and hollowing the top of the portion left standing in the ground into the form of a mortar, A. A small hole is then bored obliquely through from the bottom of the cavity to the outside, and a pipe, *f*, conveys the juice into a jar, *g*. B is a cylindrical piece of wood, sharpened at each end, to act as a pestle, which is kept in its place with sufficient pressure by the lever C and the ropes at E. Two men are required; one at I has a basket supplied with small lengths of freshly-cut cane, which he places, two or three at a time, in the mortar, and, when necessary, removes the crushed ones; the other man sits on the other end of the train, balancing it, and at the same time drives oxen which are attached to the end of the beam D, and keep the movable parts of the mill constantly turning round.

Notwithstanding the rudeness of this contrivance, very large quantities of sugar are made by it in India. A much better one, however, is the Chica Ballapura engine (fig. 2), which consists of

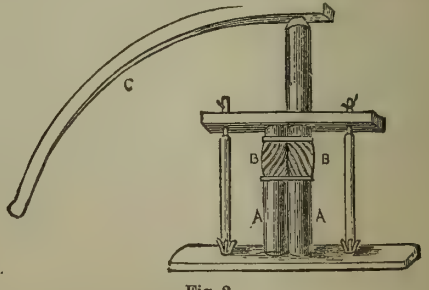

Fig. 2.

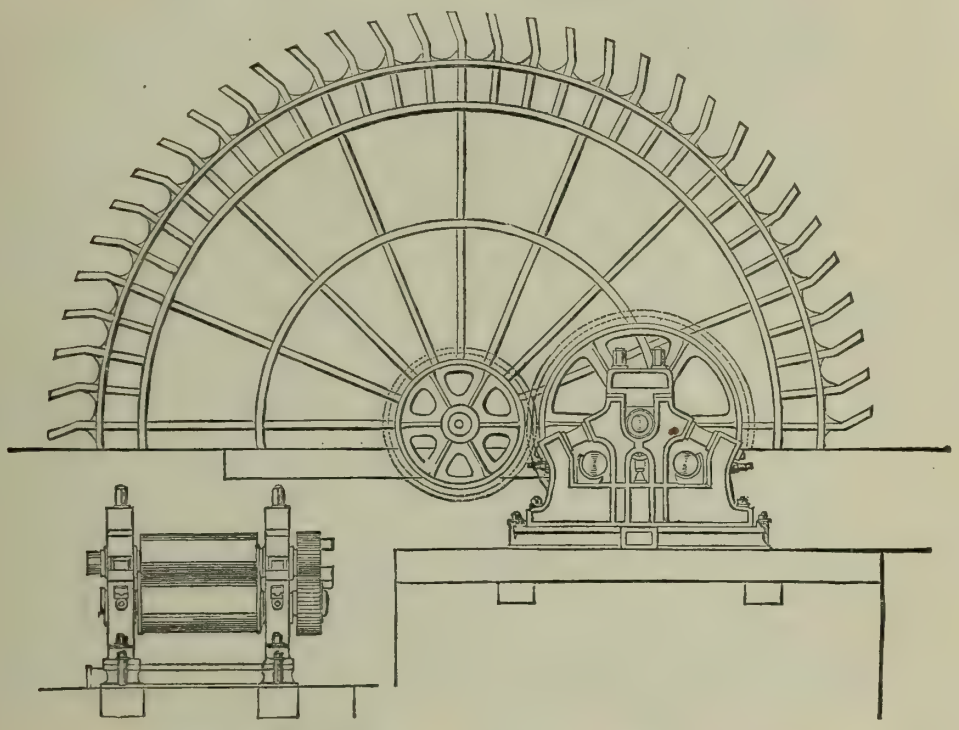
two upright rollers, A, A, the heads of which are formed into double spiral screws, B, B, which work in one another, so that

when an ox is yoked to the long curved lever, C, and goes round, one of the upright rollers, being connected with the lever, is made to revolve, and its screw carries the other one round, but in an opposite direction. The pieces of cane are fed in by hand between the rollers, and as the juice is squeezed out, it flows down into a small hollow below the frame made to receive it, whence a small trough carries it to an earthen pot. The frame of this mill is securely fixed with stakes driven deep into the ground. In all probability, this very ancient machine has been the origin of all the most modern ones, for they all consist of rollers placed either vertically or horizontally, between which the canes are made to pass.

The mills now in general use for squeezing the juice out of the sugar-canes are very powerful machines. Fig. 3 represents an end view of a cane-mill, with the iron water-wheel and gearing for drivingit, and fig. 4 represents a front view of the same mill.



FFig. 4.

Fig. 3.

Some idea of the strength of those mills will be formed from the fact, that one of the rollers weighs upwards of 5 tons. The axles are 12 inches in diameter, and notwithstanding that they are made of the best wrought iron, they are not secure against breakage. The manufacture of sugar has probably been carried to greater perfection in the islands of Java, Mauritius, and Cuba than in any other parts of the world. In Java especially, in consequence of the great extent of the plantations, the planters have been able to erect very complete establishments for the manufacture of sugar.

The following very condensed account of the process of making sugar in Java will give some idea of the operation.

The canes, freed from all loose leaves, are passed through between the rollers under the greatest possible pressure that can be brought to bear upon them. The rollers revolve only from two to four times per minute. From 100 lbs. of canes, 65 to 75 lbs. of cane-juice will be expressed. This juice, which is of a sweetish taste, and of the color of dirty water, passes direct from the mill to a small reservoir, where it usually receives a small dose of quicklime, and without delay runs off to large iron or copper vessels, heated either by a fire underneath or by steam-pipes in the liquid. As the temperature of the juice rises, a thick scum comes to the top, which is either removed by skimming, or the warm juice is drawn off from below the scum. The concentration of the juice is partly effected in a series of large open hemispherical iron pans about six to eight feet diameter, of which five or six are placed in a row, with a large fire under the one at the end. This one fire, which runs along under the whole row of pans, is found sufficient to make two or three of them nearest the fire boil violently, and in addition, it warms the juice in the pans furthest from the fire. As the juice first enters the pans furthest from the fire, it gets gradually heated, and the vegetable impurities rise in scum to the top, and are carefully removed. As the juice is ladled from one pan to the next, it boils with greater and greater vigor as it approaches nearer the fire, until in the pan immediately over the fire it seethes and foams with excessive violence; and this seems to be essential to the successful making of sugar. It is known that the presence of all those impurities which constitute the scum interferes with the crystallizing of the sugar; and the rapid ascent of bubbles of steam through the liquid in the pans carries all impurities dispersed through the body of the liquid to the top, where they can be removed with facility.

It is well known that great heat is very destructive to cane-juice; that is to say, it turns much of the crystallizable sugar into treacle or uncrystallizable sugar, but the gain arising from getting rid of much of the impurity in the cane-juice more than compensates for the destruction of part of the sugar. After the concentration has been carried to a given point, and all the scum has been got rid of, the application of a high heat, which would act with an increasingly destructive effect as the condensation becomes greater, is suspended, and the liquor, now of the color of turbid port wine, and of the consistency of oil, is drawn into the vacuum-pan, where the concentration is completed at the lowest possible temperature, generally about 150° F. The vacuum-pan shown in fig. 5, is in universal use in all European sugar-refineries

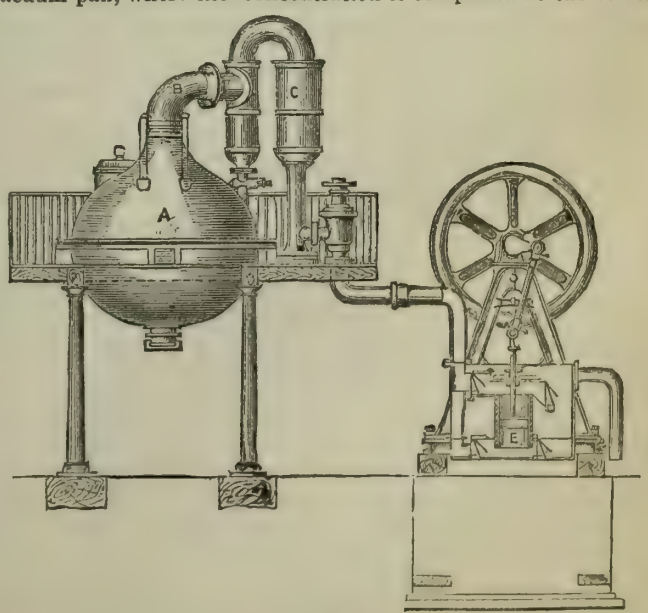


Fig. 5.

and in all well-provided sugar-plantations. It is generally made of copper, of a spherical form, and from six to nine feet in diameter. The bottom is double, leaving a space of an inch or two for the admission of steam between the two bottoms, and there is generally a long coiled copper pipe of three or four inches diameter above the inner bottom, so as to still further increase the amount of heating surface. This apparatus is made perfectly air and steam tight. Leading from its upper dome, A, there is a large pipe, B, communicating with a condenser, C, into which a rush of cold water is continually passing, so as to condense all the steam or vapor that arises from the liquid boiling in the vacuum-pan. The water which is constantly rushing into the condenser is as steadily withdrawn again by the pump at E. There is thus a constant vacuum in the pan, and, consequently, the liquid in it will boil at a much lower temperature than it would in an open pan or boiler. There is an extraordinary advantage in being able to effect the later stages of the concentration at a low temperature, for it is when the liquid becomes thick that the destructive results of a high temperature become most excessive.

As the concentration of the liquid in the vacuum-pan proceeds, crystals of sugar begin to form, and the skill of the sugar-boiler is shown by the uniformity of the crystals he produces. The boiling is commenced by filling in only about a third or fourth of the quantity the vacuum-pan will hold, and gradually adding more liquid as the crystals increase in size. The sugar-boiler is able to watch the changes going on in the vacuum-pan by means of small samples he withdraws from it by means of a suitable apparatus. The sugar-boiler holds those drops of thick fluid on his finger and thumb, between his eye and a strong light, and is thus able to detect those minute changes in its condition which show that it is time to add an additional quantity. By the time the vacuum-pan is full, the contents have thickened, by the formation of crystals of sugar, into a mass of the consistency of thick gruel; it is then allowed to descend into a vessel called the heater, where it is simply kept warm until it can be run out into the 'forms,' which, in the sugar-growing colonies, are generally conical earthen pots, holding from one to two cwts. of sugar. It is allowed to cool and complete its crystallization before the plugs, which close the bottom of the pots, are withdrawn. When this is done, from one-fourth to one-third of the contents of the form, which has remained in a fluid state, runs off into gutters leading to large tanks, from which it is again pumped up into the vacuum-pan, and reboiled, yielding a second quality of sugar. This reboiling of the drainings is repeated, with a continually decreasing result, both as to quantity and quality of the solid sugar obtained, and it is rarely carried beyond the fourth boiling. If the planter wishes to obtain Muscovada or unclayed sugar, the process is now complete, and the sugar is turned out of the forms, and packed for shipment. In some cases, the sugar is run direct from the vacuum-pans into casks or hogsheads, which replace the forms, holes being bored in the bottoms of the casks, to admit of the uncrystallized portion of the sugar draining out.

If *clayed* sugar is to be made, the forms are allowed to stand for a few days until all the treacle has drained out; and a quantity of thin mud, about the consisteny of good thick cream, is then poured over the sugar, to the depth of one or two inches. The water contained in this thin mud slowly steals down through the sugar, and mixing with the coatings of treacle still adhering to the outsides of the crystals of sugar, renders them less viscid, and facilitates their descent to the bottom of the form. The mud remains, at the end of a few days, in the form of a dry hard cake on the top of the sugar, and none mixes with the sugar.

The process of claying sugar is simply washing off a coating of black or yellow treacle from a crystal of sugar, which is always white. This operation is possible without dissolving the crystal of sugar, simply because the treacle has a greater affinity for water than the crystallized sugar has. Anything that would yield a very slow and steady supply of water to the sugar, would do as well as mud or clay. There is always some loss of crystallized sugar in the process of claying, and attempts have been made to use strong alcohol for washing off the coatings of treacle from the crystals; but although alcohol dissolves treacle very freely, and scarcely acts on the crystals at all, still it has not been found to answer commercially. Besides the cost of the process, there is a difficulty in getting rid of the smell of alcohol in the sugar.

The centrifugal machine of Messrs Manlove, Alliott, & Co., has been very extensively used for getting rid of the treacle. Its action depends on precisely the same principle as that called into play when a sailor twirls a mop to expel the water from it. The centrifugal machine is simply a drum of 3 or 4 feet diameter, and 12 to 18 inches high, revolving at a great velocity on a vertical axis. The sugar, either direct from the vacuum-pan, or after it has been allowed to cool, is put, still mixed with the treacle, into the Machine. As soon as the drum acquires a high velocity, its contents are forced by the centrifugal action against the drum, the cylindrical portion of which is made like a sieve, and admits of the escape of the treacle, but retains the crystals of sugar. Some idea of the efficiency of those machines may be formed when it is stated, that in a machine of three feet diameter, revolving at the usual speed of 1000 revolutions per minute, the tendency of the treacle to escape will be 514 times its own weight; that is to say, the treacle will have 514 times more force to fly off, than it has to drop off the crystal by the mere force of gravity.

Sugar-refining was unknown to the ancients, and even the refining previously referred to as having been established in Germany in the 16th c., consisted merely in clarifying the syrup and producing a sort of sugar-candy; but one improvement followed another, until the process may now be considered as almost perfect. The chief difficulties attending the operation arise from the circumstance that the material to be operated upon is ever varying in quality. Not only is there a difference between the produce of two different plantations, but even the manufacture of the same plantation shows differences of quality; these differences arising chiefly from the presence of foreign substances, which seriously interfere with the operations of the refiner. The attempt made to test the exact quality of solutions of raw sugar by means of polarized light (see above) have hitherto been attended with little success in practice. Sugar-refining, as practised in Britain, has three distinct objects—(1) the production of loaves of thoroughly refined sugar; (2) crushed sugar; and (3) white sugar in separate crystals. The last is of comparatively recent introduction. In some existing sugar-refineries, old fashions still prevail; but our description must be confined to the most recent methods.

Sugar-refining is carried on in this country on a great scale; London, Bristol, and Greenock being the principal seats of the trade. There is comparatively little raw sugar used in Great Britain. Nearly all the yellow and dark-colored sugar sold in the shops has passed through the hands of the refiners, and is simply inferior sugar, made out of the syrup which drains from the white loaf-sugar.

Sugar-refineries are built eight or nine stories high, and the raw sugar is first hoisted to the upper story, where it is dissolved in large tanks of hot water, care being taken to use as little water as possible for the purpose. A quantity of bullock's blood is stirred into the solution of sugar, and the heat being gradually raised, the albumen of the blood coagulates, and rises to the surface in the form of a thick light scum, bringing with it nearly all the mechanical impurities floating in the fluid. The liquor, still hot, is then passed into the bag-filters shown in fig. 6. Those filters are made of a very closely woven cotton cloth, capable of retaining the minutest mechanical impurity. In order to facilitate the passage of the liquor through the bags, they are suspended in a kind of iron closet, and surrounded by an atmosphere of steam to keep the liquor hot. From the bag-filters, the liquor, now freed from all mechanical impurities, but of a dark color, flows into a lofty cylindrical iron filter, of about 5 or 6 feet diameter and 20 or 30 feet high, filled with animal charcoal, that is, char-

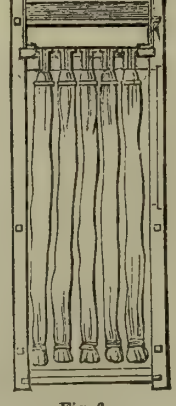

Fig. 6.

Fig. 7.

coal made of bones. This charcoal is reduced to coarse powder; and the dark offensive liquor is allowed to percolate very slowly through the mass. The result is, that it flows out at the bottom a perfectly transparent and pure solution of sugar. The charcoal can only be used for a few days at a time, becauses it gradually loses its purifying power; when the liquor begins to flow through it without being purified, it is taken out of the filter, and reburned, which completely revives its powers.

The liquor as it flows from the charcoal filter is a mixture of pure sugar and pure water, and perfectly transparent. The application of heat is the only mode of expelling the water, and this unfortunately blackens the sugar again. In order to get rid of the water with as little heat as possible, the colorless liquid is boiled in the vacuum-pan as in the early process of the manufacture (see fig. 5). The liquor boils in vacuo at about 150° F., and even this moderate heat has the effect of turning it quite

brown. When it has been sufficiently concentrated by boiling in the vacuum-pan, which takes from 1½ to 2½ hours, it is run into the sugar-loaf forms (fig. 7); which, after cooling, are carried to a room kept warm by means of steam-pipes. This warmth facilitates the flow of the treacle or syrup out at the aperture seen at the bottom of the form. To get rid of the coating of colored treacle which still hangs about the crystals of sugar, a small quantity of a saturated solution of pure white sugar is poured on the top of the form. This strong liquor is unable to dissolve any more sugar, but being more fluid than the sticky coatings of treacle or syrup adhering to the crystals, it mixes with the coatings, and makes them fluid enough to flow down to the bottom of the form, leaving the crystals clear of syrup or treacle, and consequently free of all color. This process of washing off the coloring matter from the crystals of sugar is the same in principle as the 'claying' used in the production of sugar. The loaves of sugar, after standing some time, to admit of all the liquor draining off, are wrapped in paper, and dried in stoves heated by steam. The liquor draining from the forms is reboiled in the vacuum-pan, and forms loaves of an inferior quality; and the liquor draining from the inferior loaves is again boiled into the yellow sugars known amongst sugar-refiners as bastards.

Crushed or Crashed Sugar is simply inferior loaves crushed while still soft and moist, and packed in hogsheads, instead of being left in the loaf form.

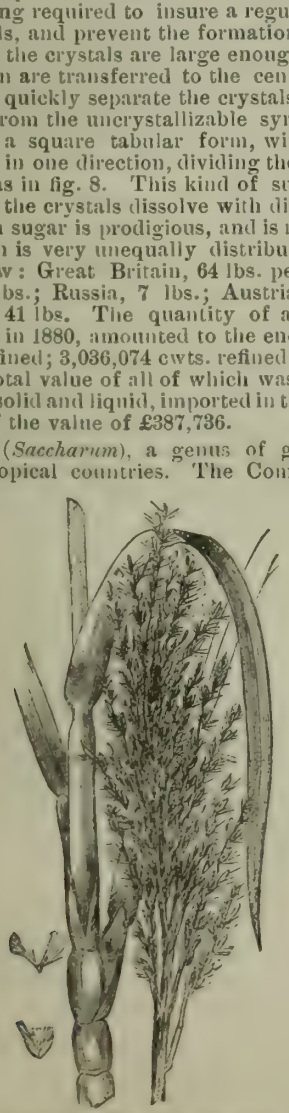
The syrup which drains from refined sugar is reboiled, and constitutes the *Golden Syrup* of the shops.

Crystal Sugar.—In making the sugar crystals, all the processes are carried on as in refining, until the syrup is clarified. Then it is boiled or concentrated in a vacuum-pan of larger size than ordinary, and the concentration is carried on until minute crystals appear. Fresh syrup is then added from time to time, great care and experience being required to insure a regular feeding of the first-formed crystals, and prevent the formation of a second crop. When the crystals are large enough, the contents of the pan are transferred to the centrifugal machines, which quickly separate the crystals in a perfectly dry state from the uncrystallizable syrup. The crystals are of a square tabular form, with a deep groove across in one direction, dividing the crystal into equal parts as in fig. 8. This kind of sugar is much liked for coffee, &c., but the crystals dissolve with difficulty.

Fig. 8.

The commerce in sugar is prodigious, and is rapidly increasing; but its consumption is very unequally distributed. The proportions are as follow: Great Britain, 64 lbs. per head; France, 4 lbs.; Belgium, 6 lbs.; Russia, 7 lbs.; Austria, 1½ lbs.; United States of America, 41 lbs. The quantity of all kinds imported into Great Britain, in 1880, amounted to the enormous sum of 17,001,613 cwts. unrefined; 3,036,074 cwts. refined; and 211,541 cwts. of molasses; the total value of all of which was £23,368,823. Besides, the glucose, solid and liquid, imported in that year, amounted to 405,760 cwts., of the value of £387,736.

SUGAR-CANE (*Saccharum*), a genus of grasses, natives of tropical and sub-tropical countries. The Common S. (*S. officinarum*) is originally a native of the East Indies, was brought to the south of Europe by the crusaders, and in the 15th and 16th centuries found its way into all the European colonies within the tropics. In Europe the cultivation of the S. has always been very limited, and is scarcely practised except in Sicily and Andalucia. In China, it extends to 30° N. lat., and in North America to 32°; in the southern hemisphere only to 22° S. lat. The plant is a perennial, with a creeping root, sending up a number of culms or stems generally 8—12 feet high, which have many joints, are of various colors, and about 1—2 inches thick. They are filled for about two-thirds of their length with a loose, sweet, juicy pith. The leaves are ribbon-shaped, and 4—5 feet long, with a strong whitish middle nerve. The flowers are in great diffuse pyramidal panicles of a yard in length.—The Violet-colored S. (*S. violaceum*) is particularly esteemed, and much cultivated in the West Indies.—The Chinese S. (*S. Sinense*), cultivated in China, has the stem in great part covered with the sheaths of the leaves. Cultivation has produced many varieties of these species; if, indeed, they are originally distinct species, and not themselves mere varieties.—The species of *Saccharum* are numerous; they contain much silica in the rind, and some of them are much employed in India for thatching and for making mats, as well as for screens and light fences. The Bengalese make their pens of the hollow stems of *S. semidecumbens* and *S. fuscum*.



Sugar-cane (*Saccharum officinarum*).

The S. is usually propagated by cuttings. For this purpose the top joints are used. The cuttings are planted in rows three or four feet apart, and at intervals of about two feet in the rows. The largest varieties, in rich moist soils, attain a height of 20 feet; but in dry poor soils, the height is sometimes scarcely more than 6 feet. The plant *tillers* like wheat, but not to the same degree. The cane-ground is kept clean by hand-hoeing, or by the plough. Hand-hoeing was formerly universal in the West Indies, but the plough is now very generally used where the nature of the ground permits. The best varieties are ready for cutting in about ten months from the time of planting, but other varieties require a longer period of growth, from 12 to 20 months. When the canes are fully ripe, they are cut a little above the ground, and tied in bundles to be conveyed to the mill. Fresh canes, called *rattoons*, spring from the root, so that the plantation does not require to be renewed for several years; but the canes of the first crop are the largest and a gradual decrease of size takes place. The ordinary practice on sugar estates is to renew a part of the plantation every year.

The name CHINESE SUGAR-CANE is sometimes given to the SHALOO or SUGAR-GRASS (*Sorghum saccharatum*), already noticed in the article DURRA. A still more important sugar-yielding grass is the ordinary maize or Indian corn. The sorghum became known in America in 1857, and has latterly been extensively cultivated for producing syrup. It has long been known that sugar could also be obtained from the stalks of maize; but neither sorghum sugar nor maize sugar could till lately be made so as to compete commercially with the produce of the sugar-cane. Recently, however, an American gentleman—Mr. Stewart of Murraysville, in Pennsylvania, has discovered a method of obtaining from both sorghum and maize crystallized sugar equal to the best kinds known. The processes are somewhat simpler than those in use for the sugar-cane, and are more economical than those employed in making beet-sugar. The quantity is also abundant. It has been calculated that, on an average, one acre of maize may yield 1800 pounds of sugar and 44 gallons of molasses; and that the yield of sugar from one acre of maize will give as good a profit as could be got from thirty acres of wheat. (See report of Mr. Drummond, British Secretary of Legation at Washington in 1878.) Two per cent. of the area now given to maize would serve to supply the enormous demand for imported sugar in the United States. It is therefore easy to see how great would be the effect produced in the sugar-trade of the world if the United States were to utilize for their own use, as they may now easily do, their own sugar supplies; still more if they should become a sugar-exporting country.

SUGAR-OF-LEAD, the common name for Acetate of Lead. See LEAD.

SUHL, a town of Prussia, province of Saxony, and government of Erfurt, is situated on a small stream, called the Lauter, in a romantic valley on the south-west side of the Thuringian Forest, 32 miles south-south-west of Erfurt. The name S., which in the Sorb-Wendish dialect means salt, is probably derived from the salt springs, formerly much worked. Mining is extensively carried on in the neighborhood, and has been so for centuries. The principal manufactures are iron and steel wares, chemical preparations, paper, and leather. S., celebrated in the days of chivalry as the 'Arsenal of Germany,' still maintains its ancient reputation as a manufactory of arms. Pop. (1880) 19,937. Its history is very interesting; see Werther's *Sieben Bücher der Chronik der Stadt Suhl* (1817).

SUHM, PETER FRIDERIK, a Danish historian, was born in Copenhagen, 18th October 1728, of an ancient and noble family, and was sent to the university of Copenhagen, where he gradu-

ated in law in 1748. A few years later, he went to Norway, for the sake of prosecuting his studies in philology and history, in conjunction with the learned historian Schöning, and did not return till 1765 to Copenhagen, where he continued to reside till his death in 1798. Among his numerous works on the early mythical and political history of Denmark we may instance the following: *Forsoeg til Forbedringer i den gamle danske og norske Historie* (1757); *Om de nordiske Folks ældste Oprindelse* (1770); *Om Odin og den hedenske Gudelære* (1771); *Critisk Historie af Danmark i den hedenske Tid*, i.—iv. Band (1774—1781); *Historie af Danmark*, 1*ste Tome* (1782). Besides numerous other historical essays, moral treatises, poetic compositions, contributions to the philosophical and literary periodicals of Germany, France, and Denmark, &c., he edited *Scriptores Rerum Danicarum Medii Ævi*, from vol. iv. to vol. vii. inclusive (Hafniæ, 1776—1792), and took upon himself the cost and supervision of the publication of many remains of old northern literature.

S. was an indefatigable collector of rare and curious books; and in 1796, in return for a pension from the government, he made over to the Royal Library of Copenhagen his valuable library of 100,000 volumes, to which he had previously allowed the public access. After the death of his only son, he devoted the greater part of his ample means to the purpose of having copies made of the more valuable MSS. in the collection, many of which were, moreover, printed at his sole charge; besides which, he founded scholarships, and afforded direct pecuniary assistance to many poor students and learned men. He died in 1798. S.'s collective writings were brought out by S. Poulsen, in 16 vols., between 1788—1799; and various editions of his lesser works have at different times appeared in Germany, as well as in Denmark, where he is justly regarded as one of the most learned and laborious and patriotic writers of his country.

SU'ICIDE (Lat. self-murder) is a heinous crime, by the law of the United Kingdom, though it was treated as venial by the Roman law, and was the subject of panegyric by Stoic philosophers. The law of England treats it as a felony, and hence there may be accessories to it, so that if A persuade B to kill himself, and B does so, A is guilty of murder. Suicide, or *felo de se* (q. v.), not only includes one who deliberately kills himself, but also one who in maliciously attempting to kill another is himself killed. If A, however, requests B to kill him, and B does so, A is not a *felo de se*, though B is a murderer. If A and B mutually agree to commit suicide together, and in the attempt one only dies, the other is guilty of murder. When it is said that a man was a suicide, this implies that he was in his senses, for otherwise he committed no crime; hence an insane person, unless when in a lucid interval, cannot commit the crime. The punishment inflicted on a suicide consisted, formerly, in an ignominous burial in the highway, with a stake driven through the body, and without Christian rites; also the legal consequence was forfeiture of the goods and chattels to the crown. The only consequences now are forfeiture of goods.

An act of 1824 permitted burial in churchyards without rites, between 9 and 12 P.M.; the Interments (Felo de se) Act of 1882 sanctioned burial at any hour, and with the usual rites. An attempt to commit suicide is not punishable like an attempt to murder a third party, nevertheless it is a misdemeanor. The consequences of suicide on the contract of life-assurance are generally guarded against by an express stipulation, that if the assured die by his own hand, the policy shall be void; and it has been held by the courts that the policy is forfeited, even though the party destroyed himself in a fit of frenzy or delirium.

There are, no doubt, even in modern times, some who hold the theoretical opinion that suicide is permissible in certain circumstances; but in regard to those who have actually committed or attempted the crime, there has almost always been detectable evidence of cerebral changes; or, at all events, of that irritation and excitement which initiate and accompany molecular disorganization of the nervous structure. In short, suicide, as a rule, is a symptom of some form of insanity, permanent or temporary, in which the emotions and passions are excited or perverted. Suicide is likewise a concomitant of certain bodily diseases; for example, of dilatation and fatty degeneration of the heart, of blood-degeneration, of affections of the intestinal mucous membrane, of the uterus, and of the brain and nervous matter; and it may be regarded as a frequent sequence of the melancholic, the morose, and hypochondriacle temperament. It has appeared as an epidemic; it has been observed as a hereditary tendency in certain families; and as a tendency more frequently exhibited by males than females; more frequently by the educated and affluent than by the industrial and ignorant classes; most frequently in large cities; and as directly engendered by luxury, political agitation, gambling, intemperance, and demoralization. It would appear, however, that indulgence and asceticism, riches and extreme poverty, claim nearly an equal number of victims. It has been calculated that twice as many artisans commit suicide as laborers.

In 1840, it was found that in every 10,000 of the population, 1·33 masons, carpenters, butchers; 7·43 tailors, shoemakers, bakers; 4·9 bankers, professionals; 2·0 of persons assured in Equitable Office; 7·8 dragoons; 6·7 servants and coachmen; 4·0 paupers, died by their own hand. Observation has shown that from 20 to 35 is the most influential age in inducing the suicidal tendency; and the age appears to determine, to a certain degree, the modes of death selected as well as the proclivity. As might be expected, the nature of the delusion, the accessibility of the means, imitation, the profession or pursuit of the individual, novelty, and notoriety, all influence the choice of the instrument or means of death. The theomaniac dies by crucifixion; the great majority by ropes, rivers, wells, razors, arsenic; the medical man by aconite, chloroform. Even sex is characterized by peculiar preferences. Females seek voluntary death according to the following order of the means—hanging or strangulation, abstinence, precipitation, drowning, cutting, poison; males, again, according to this order —cutting, shooting, hanging, poison, drowning. Race, climate, country, and the distinguishing polity of different societies to a certain extent affect the proportion of suicides to the population. In the kingdom of Sweden, there is calculated to be one suicide to every 92,375 inhabitants; in Saxony, 1 to 8446; in Russia, 1 to 34,246; in the United States, 1 to 15,000. In Paris, 1 suicide occurs in 2700; in St. Petersburg and London, 1 in 21,000 citizens. Middlesex, again, is the most prolific of all English counties; Chester least so: there being in the former, 10·5, in the latter, 7·2 to 100,000 people. In all England, the proportion is 7·4.—*Anatomy of Suicide*, Forbes Winslow; *Du Suicide*, Brièrre de Boismont; *Traité du Suicide*, Bertrand; *Suicide*, by Morselli (Lond. 1881); *Suicide: Studies on its Philosophy, its Causes and its Prevention*, by O'Dea (New York, 1882).

SU'IDÆ, a family of Mammalia, non-ruminant Artiodactyla (q. v.), having the feet generally four-toed, the hinder feet sometimes three-toed; the toes hoofed, the two front toes forming the principal part of the foot, the others smaller and scarcely touching the ground; the snout abruptly truncated, mobile, muscular, and sensitive, but not elongated into a proboscis; the tail short, or almost wanting; the incisor teeth variable in number, the lower ones all directed forwards, the canines projecting, and bent upwards; the stomach little divided. To this family belong hogs, wart-hogs, peccaries, &c.

SUIDAS, the name given to the compiler of a *Lexicon* some time during the Byzantine Empire. When he lived, or who he was, or whether he was even called S., no one can say; but it is customary to place him about the 10th or 11th century. The *Lexicon* bears unmistakable evidence of having gone through many hands; and though we can fix the date when several of the articles *must* have been written, it is impossible to ascertain whether they are the composition of the first compiler or of a later editor. The work is a sort of cyclopædia, giving an explanation of words, and notices of persons, places, &c., in alphabetical order. It is utterly destitute of literary or critical merit, but is valuable in the eyes of scholars on account of its numerous extracts from ancient Greek writers, grammarians, scholiasts, and lexicographers, whose writings in many cases have perished. The first edition appeared at Milan (1499); since then the best editions have been those of Küster (Camb. 3 vols. 1705), Gaisford (Oxf. 2 vols. 1834), Bernhardy (Halle, 2 vols. 1834), and J. Bekker (Berl. 1854).

SU'I JU'RIS, in the Roman law, the condition of a person not subject to the *Patria Potestas* (q. v.). The paterfamilias was the only member of a family who was *sui juris*, all the rest being *alieni juris*, including sons, unmarried daughters, the wife, and the wives and children of the sons of the paterfamilias. A daughter, on her marriage, passed into the family of her husband; but a son did not become *sui juris* by marriage. A son or unmarried daughter became *sui juris* on the death of the paterfamilias. In his father's lifetime, a son could only become *sui juris* by emancipation. The laws of the Twelve Tables declared that a son three times sold by his father should be freed from his power; and the ceremony of emancipation was of the nature of a fictitious sale gone through three times, in order to liberate the son from parental control. *Connubium* being the foundation of the *patria potestas*, a bastard was *sui juris*.

SUIR, a river of Ireland, rising in the north of the county of Tipperary, flows south through that county by the towns of Thurles and Cahir. Ten miles south of Cahir it bends eastward, forming the boundary of Tipperary and Waterford, and passing by Clonmel and Carrick. It then passes out of Tipperary, and meeting the Barrow at Passage, Waterford, falls into the sea in Waterford Haven, after a course of about 100 miles. It is navigable by barges as far as Clonmel.

SUIT IN CHANCERY was the process corresponding to an action in a court of law. The suit generally commenced with a bill, i. e., a petition to the Lord Chancellor, which set forth the grievance, with a prayer for redress. It was signed by counsel, and was served on the defendants, either personally or at the

dwelling-place. They had then to enter appearance, and put in either an answer or a demurrer, or a plea, which were the several defences to the suit, according to the nature of the subject-matter. Since 1876, all suits have been called actions, but the procedure is not much changed. An appeal lies from the Chancery division of the High Court to the Court of Appeal, and finally to the House of Lords.

SUL, Rio Grande do. See Rio Grande do Sul.

SULIMA'N MOUNTAINS, a mountain range upwards of 350 miles in length, running from north to south, and forming the boundary between Afghanistan and the Punjab. In lat. about 33° 20′, it throws off the lateral branch of the Salt Range (q. v.). The highest summit of the range is Tacht-i-Suliman (Solomon's Throne), 11,000 feet high, and covered with snow for three months of each year.

SULI'NA, one of the lower branches of the Danube (q. v.), flows through the middle region of the delta of the great river, and enters the sea at about the same distance from the Kilia mouth on the north and St. George's mouth on the south. It is the smallest outlet of the Danube, and conveys only $\frac{8}{17}$ths of the main river to the sea; but its channel through the bar that lines the coast is deeper than that of the other mouths, and therefore the S. is more frequented by vessels than any other branch of the Danube.

SU'LIOTS, a tribe who inhabited the valley of the Acheron, in the pashalik of Janina (*Epirus*) in European Turkey, are a mixed race, being partly of Hellenic and partly of Albanian origin. They are the descendants of a number of families who fled from their Turkish oppressors to the mountains of Suli (whence they derive their name) during the 17th century. In this obscure corner of the Turkish Empire they prospered, and towards the close of the 18th c., numbered 560 families, inhabiting 90 hamlets. For about 15 years they heroically resisted the encroachments of Ali Pasha (q. v.) of Janina upon their independence, the very women taking part in the strife. Vanquished in 1803, they retreated to Parga, and afterwards to the Ionian Islands, where they remained till 1820, when their old oppressor, Ali Pasha, finding himself hard pressed by the Turks, invoked their aid, offering them guarantees for his faith, and his grandson as a hostage.

Eager to return to their cherished home, they accepted these terms, and under Marcos Bozzaris (q. v.), maintained a long and desperate conflict with the Turks, but were ultimately forced again to flee from their country, and take refuge to the number of 3000 in Cephalonia, though a large remnant preferred to skulk in the neighboring mountains. Though they took a glorious part in the war of Greek independence, their country was not included by the treaty of 1829 within the Greek boundary-line; but most of them established themselves in Greece, where their leaders were raised to important offices. The old seat of the S. lies in the portion of Epirus which the Berlin Congress of 1878 recommended to be restored to Greece—a recommendation not carried out at the rectification of the Greek frontier in 1881.—See Perrhaebos's *History of Suli and Parga* (1815; trans. 1823).

SU'LLA, L. Cornelius, surnamed by himself Felix, the ablest Roman after the younger Scipio until the appearance of Julius Cæsar, was born 138 B.C. His family was a member, but not a distinguished one, of the Cornelian *gens*, or 'clan.' In 107 B.C., he was elected quæstor, and sent to Africa with the cavalry that the consul Marius (q. v.) required for prosecuting the Jugurthine War. He rapidly acquired a brilliant reputation as an officer, and crowned a series of important services by inducing Bocchus, the Mauritanian king, to surrender Jugurtha, whom he brought in chains to the Roman camp (106 B.C.). Marius was not over well pleased at the distinction achieved by his subordinate. In the campaigns that followed (104—101 B.C.) against the Cimbri and Teutones, S.'s reputation continued to rise, although Marius was still regarded (and with justice) as the first general of the state.

For several years after the destruction of the barbarians, S. lived quietly, taking no part in public affairs; but in 93 B.C. he stood for the prætorship, and won it by a liberal distribution of money among the people. Next year, he was sent to Cilicia as proprætor, to replace Ariobarzanes on the throne of Cappadocia, from which he had been driven by Mithridates. On his return to Italy (91 B.C.), the long-smouldering animosity between Marius and him was on the point of bursting forth, but the terrible *Social War* forced all Romans to postpone their quarrels until the common danger had been averted. Both Marius and Sulla commanded armies in this great struggle; but the successes of S. threw those of Marius into the shade, and the mortification of his rival was deep and bitter. In 88 B.C., S. was elected consul along with Q. Pompeius Rufus, and the senate conferred on him the command of the Mithridatic War. But this was a command that Marius himself passionately desired, and when he heard that S. had obtained it, he rushed headlong into treason and civil war.

Here it may perhaps be necessary to observe that Marius and S. were not only personal rivals, but the leaders of opposite political parties. The former, a man of humble origin (see Marius), was a rough, stubborn, irascible, and alliterate *plebeian*; the latter a finely cultivated *patrician*, subtle and sagacious in policy, and winning in manners. In the terrible scenes that ensued, although S. showed himself by far the fiercer and more sanguinary of the two, it should not be forgotten that it was Marius who commenced the contest. Allying himself with the tribune P. Sulpicius Rufus, a political adventurer in difficulties, Marius placed himself at the head of the new Italian party, on which the rights of Roman citizenship had been conferred, and hoped to force the senate to recall the appointment of S. to the command of the expedition to the East. S. was compelled to flee to Nola in Campania, where his camp then was; but finding the soldiers full of enthusiasm, he resolved to lead them against the pseudo-government that had been established at Rome.

The story of the overthrow of the Marian party, the expulsion of Marius, and his subsequent wanderings in Africa, &c., are well known, and intimately as these events are inwoven with the fortunes of S., cannot be repeated here. Suffice it to say, that after settling affairs at Rome as well as he could, S. embarked for the East (87 B.C.), and was away for four years. Most of his fighting, however, was done in Greece against Archelaus, an ally of Mithridates, whom the latter repeatedly subsidized with men and money. Athens was stormed and plundered (86 B.C.), and Archelaus himself was defeated with frightful slaughter at Chæroneia in the same year, and again in the neighborhood of Orchomenos (84 B.C.). S. now crossed the Hellespont, crushed Fimbria, a general sent out by the Marian party (which, in S.'s absence, had again got the upper hand in Italy), forced Mithridates to sue for peace, and after extorting heavy contributions from the cities of Asia Minor, sailed for Italy, and landed at Brundusium in the spring of 83 B.C. Marius was now dead, but his party were strong in numbers, if not in organization; yet, before the close of 82 B.C., the Marian party in Italy was utterly crushed. In Spain, however, under the gallant and high-souled Sertorius (q. v.), it held out for ten years longer.

When S. felt himself master of the situation, his thoughts turned to revenge. Then followed the fearful period of the *proscriptions* (81 B.C.)—a virtual 'Reign of Terror' throughout Italy, the object of which was literally to extirpate the Marian party. In this, however, it was only partially successful; and the next generation saw that party rise to more splendid predominance than ever in the person of Julius Cæsar (q. v.), nephew of old Marius. In 81 B.C., S. got himself appointed dictator, an office which he held until 79 B.C. This period was signalized by his framing a series of laws—often spoken of collectively as the 'Sullan legislation'—the design of which was to make the senate and the aristocracy as vigorous and powerful as in the times of the Punic Wars, but which utterly failed of its end.

On resigning his dictatorship, S. retired to his fine estate at Puteoli, to enjoy at his ease those sensual pleasures to which he had been deeply addicted from his earliest manhood. Literature, wine, and women were luxuries in which he had always indulged, but now he wholly devoted himself to them—in a sort of *swinish* manner. It is strange to reflect that the man who undertook to legislate with the view of mending the public morals, should himself have surpassed in profligacy all his contemporaries. What more convincing proof could we have that morality in Rome had ceased to be more than a name! S.'s debaucheries hastened his end. He died 78 B.C., when only 60 years of age, of the disgusting disease known as *Morbus Pediculosus*.

SU'LLIVAN'S ISLAND, a large island, six miles below Charleston, South Carolina, U. S., between the harbor and ocean, the site of Fort Moultrie, now dismantled, and of the summer residences of the wealthy inhabitants. When Fort Moultrie was evacuated by Major Anderson, December 26, 1860, several batteries were erected on the shore of this island, bearing upon the channel and Fort Sumter.

SULLY, Maximilien de Bethune, Duke of, the celebrated minister of Henry IV. of France, was the second son of François, Baron de Rosny, and was born at Rosny, near Mantes, in 1560. The Rosny family, an offshoot from the great House of Flanders, was never possessed of much wealth or influence, and had severely deteriorated in both respects during the early religious wars. S. was at an early age committed to the care of Henry of Navarre, the head of the Huguenot party, which not only obtained for him an excellent education, but laid the foundation of a companionship which lasted, without intermission, till Henry's death. After narrowly escaping during the St. Bartholomew massacre, he accompanied his patron in his flight from court (1575), and during the civil war which followed, exerted himself to the

utmost, by daring valor in the field and otherwise, to serve the master for whom he cherished the most absorbing devotion.

After Henry's authority had been well established, S., who had for some years previous been his trusted adviser, became (1594) counselor of state and of finance. The financial affairs of the country were then in a frightful condition; from the chief of the department down to the very lowest country agent, the administration was an organized system of pillage, and but a small percentage of the taxes levied found its way into the imperial treasury. The Baron de Rosny was the very man to remedy this state of matters; rude, obstinate, and haughty, but at the same time resolute, active, indefatigable, wholly devoted to his master's interests; and backed by the influence of Gabrielle d'Estrees, and by Henry's own clear-sighted convictions, he cared nothing for the clamor and hatred of the court, which had largely profited by the former state of chaos. Not content with regulating the affairs of the revenue from the seat of power, he made a tour through the chief provincial districts, armed with absolute authority, personally examined the accounts, dismissed or suspended delinquents, and largely replenished the treasury with the ill-gotten wealth which he compelled them to disgorge. By indomitable perseverance, he little by little brought the affairs of the country into an orderly state; although in the diminution of the expenditure his efforts were by no means so successful, as the king, his mistresses, and the other companions of his pleasures, combined to oppose all retrenchment as far as they were concerned. In 1596, the disposable revenue of the state was 7—9 millions; in 1609, it was no less than 20 millions, with a surplus of 20—22 millions in the treasury, and the arsenals and fleet in a state of excellent equipment. S., however, was more than a mere financier; he had the supreme charge of various other branches of the administration, zealously promoted agriculture by diminishing the taxes of the peasantry, encouraging export trade, draining marshlands, and constructing numerous roads, bridges and causeways.

S. was the servant of the king and government alone, and was of necessity disliked by the people for his severity, by the Catholics for his religion, and by the Protestants for his invariable refusals to sacrifice the smallest jot of his master's or the country's interest for their sake. Accordingly, with the death of Henry, his career of supremacy was at once ended, and he was forced to resign the superintendence of finance, 26th January 1611, though he retained his other high offices, and was presented by Maria de Medicis with 300,000 livres as acknowledgement of his services. He had been created Duke of Sully and Peer of France in February 1606. S. wrote three treatises on war and police, which are lost, and two pieces of verse, which are extant; but the work which will ever be connected with his name is the *Mémoires des sages et royales Œconomies d'Estat de Henry le Grand;* a dull, wearisome, and disorderly collection of writings, but of priceless value to a historian of Henry IV.'s time. S. printed the first two volumes of the *Mémoires* at his own château of Sully in 1634, the third and fourth were published at Paris in 1662, and the whole has been several times republished, as well as translated into English, German, and Russian. S. died at Villebon, near Chartres, (Eure-et-Loir), 22d December 1641. Artists have generally represented S. as older than Henry IV., while in reality he was seven years younger.

SULMO'NA, or SOLMONA, a city of Southern Italy, province of Aquila, in Abruzzi. Pop. (1881) 17,600. It is situated in a vast fertile plain, watered by two rivers, and bounded by hills. It is very well built, having one very wide street in the center of the city. There is a handsome town-hall, a cathedral, and a convent dedicated to S. Pietro Celestino, built with stones from the ancient *Corfinium*. It has paper manufactories, dye-houses, and tan-yards. S. was the birthplace of Ovid. In the 8th and 9th centuries, it was sacked by the Saracens, but was restored under the Normans, and has ever since been a flourishing and industrious city.

SU'LPHATES. See SULPHURIC ACID.

SU'LPHIDES, METALLIC, formerly known as *Sulphurets*, are combinations of sulphur with a metal. Many of them occur native, and form highly valuable ores. They are all solid at ordinary temperatures, and, with the exception of those of potassium, sodium, calcium, strontium, barium, and magnesium, are insoluble in water; they are, moreover, conductors of electricity. Many of them, especially of those that occur native, exhibit very brilliant and characteristic colors. The same metal may have several sulphides, and in general there is a sulphide for each oxide. The sulphides are, however, sometimes the more numerous. Most of these compounds may be fused at a heat a little above redness, and if the air be excluded, the protosulphides (those containing one atom of sulphur and one atom of metal) remain unaffected; but many of the higher sulphides, such as the bisulphide of iron (FeS_2) and the bisulphide of tin (SnS_2), give off an atom of sulphur, and are reduced to protosulphides. If, however, there is a free admission of air or of oxygen gas to the heated sulphides, they are all decomposed, the sulphur becoming oxidized, and passing off as sulphurous acid (SO_2), while the metal usually remains in combination with oxygen. When heated before the blowpipe, most of the sulphides evolve an odor of sulphurous acid, and very small quantities of soluble sulphides may be detected in neutral or alkaline solutions by the addition of a solution of nitroprusside of sodium ($Na_2.Fe_2Cy_5NO_2 + 4Aq$), when a magnificent purple color, which, however, is not permanent, is evolved. It has very recently been discovered by Mr. Barrett, and announced in his paper 'On some Physical Effects produced by the contact of a Hydrogen Flame with Various Bodies,' in the *Philosophical Magazine* for November 1865, that the sudden appearance of a blue color when the hydrogen flame is brought in contact with a body containing sulphur, is a most delicate test for the presence of this element, detecting it even when the nitroprusside of sodium test fails. By this test Mr. Barrett detected $\frac{1}{100000}$th of a grain of sulphur.

The sulphides are prepared in various ways, of which it is sufficient to notice the most important. (1.) The protosulphides of the metals of the alkalies and alkaline earths may be obtained by decomposing their sulphates by igniting them in closed vessels with charcoal, the oxygen being removed in the form of carbonic oxide. (2.) Many of the metals, when heated with sulphur, combine directly with it; sulphide of iron, for example, is usually prepared in this manner. (3.) Hydrated sulphide of tin, titanium, molybdenum, tungsten, vanadium, arsenic, antimony, bismuth, copper, lead, mercury, silver, gold, and platinum with its allied metals, may be obtained by passing a stream of sulphuretted hydrogen through neutral or acid solutions of their salts, when they are precipitated in an insoluble form; and the hydrated sulphides of zinc, iron, manganese, cobalt, and nickel may be prepared by double decomposition, by mixing a solution of the salt of the metal with a solution of a sulphide of one of the metals of the alkalies, as, for example, sulphide of potassium: thus, sulphate of zinc, if mixed with sulphide of potassium, yields sulphate of potash, which remains in solution, and sulphide of manganese, which falls as an insoluble precipitate. 'In many cases,' says Professor Miller, 'the atoms of these hydrated sulphides are characteristic of the metal; for example, the hydrated sulphide of zinc is white; that of manganese, flesh red; those of cadmium, arsenic, and persulphide of tin are yellow; that of tersulphide of antimony is orange red; and that of the hydrated protosulphide of tin is chocolate brown. The sulphides of molybdenum, rhodium, iridium, and osmium are brown, each with its peculiar shade, whilst in a large number of instances—including the sulphides of iron, cobalt, nickel, uranium, vanadium, bismuth, copper, lead, silver, mercury, gold, platinum, and palladium—the precipitated sulphides are of a black, more or less pure.'—*Inorganic Chemistry*, 2d ed. 1860, p. 322. A recollection of the colors of these precipitates will save the young chemist a large amount of labor in testing for the presence of the metals.

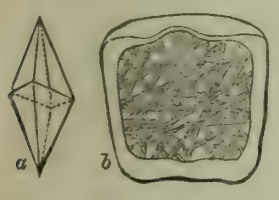
SULPHOCYA'NOGEN AND THE SULPHOCYA'NIDES. The former of these terms is given to a monobasic radical, C_2NS_2 or CyS_2, which has never yet been isolated, but which forms an acid compound, known as hydrosulphocyanic acid (H,C_2NS_2), with hydrogen, and yields numerous metallic salts. These salts, known as sulphocyanides, may be represented by the general formula, M,CyS_2, where M represents any metal. The sulphocyanides of potassium, sodium, and ammonium are crystallizable and soluble in water; those of the heavy metals are comparatively insoluble. These salts do not possess the poisonous character of the cyanides. *Sulphocyanide of potassium* (K,CyS_2) is anhydrous, but very deliquescent, and occurs in long streaked colorless prisms, somewhat resembling niter both in appearance and taste; it is extremely soluble in water, and fuses on the application of a gentle heat. The *sulphocyanide of mercury* is a white powder which possesses the property of swelling or growing in size to an almost incredible degree when moderately heated, so as to decompose it into a mixture of mellon ($C_{18}N_{18}$), with a little sulphide of mercury. The resulting mass often assumes a most fantastic shape, and is sufficiently coherent to retain its form; it is of a yellow color externally, but black within. It is this sulphocyanide which is the ingredient of the well-known toy known as 'Pharaoh's serpents.' Each serpent consists of a little cone of tinfoil, resembling a pastille in shape, and filled with the above-named compound. On lighting the cone at the apex, there begins to issue from it a thick serpent-like coil, which continues twisting and increasing in length to an extraordinary degree, the serpent-like shape resulting from the salt being burned in the tinfoil cone. The compound is readily obtained by precipitating a strong solution of pernitrate of mercury with sulphocyanide of ammonium, which is most cheaply prepared by Mr. Wood's method from bisulphide of carbon.

SULPHOVI'NIC or SULPHETHY'LIC ACID (HO,C_4H_5O,S_2O_5) is formed by mixing alcohol with an equal bulk of oil of vitriol. Great heat is evolved, and the two bodies enter partially

into combination; this new compound acid possessing only half the saturating capacity of sulphuric acid. In connection with the theory of the formation of ether from alcohol and sulphuric acid, it may be observed that this sulphovinic acid is developed as an intermediate product, if the temperature be raised to 212°, but not otherwise. This is one of the class of acids to which the term *vinic acids* is applied.

SU'LPHUR (symb. S, eq. 16—new system, 32—sp. gr. of rolled sulphur, 1·98 [see ATOMIC WEIGHTS], and of amorphous sulphur, 1·957; sp. gr. of vapor, 6·617 at 824°, and 2·2 at 1900°, atmospheric air being the unit of comparison for the vapor) is one of the most important of the non-metallic elements. At an ordinary temperature, it exists as a solid, brittle, tasteless, and inodorous body, of a characteristic yellow color, and insoluble in water. A piece of solid sulphur, heated to a temperature of 239°, fuses into a thin yellow liquid; while in closed vessels, it may, by a further heat, be distilled, the boiling-point being about 824°, and at this temperature it yields a deep yellow vapor, of sp. gr 6·617. When the sulphur-vapor comes in contact with cold air, it condenses in the form of a fine yellow powder, known as *Flowers of Sulphur*. If fused sulphur be rapidly cooled, it solidifies into a compact mass, of a granular crystalline texture; and if, in its liquid state, it be allowed to run into cylindrical wooden moulds, we obtain it in the ordinary form of roll-sulphur, or common brimstone; if, on the other hand, it be allowed to cool slowly, it crystallizes in long, glistening, deep, yellow, oblique prisms, with a rhombic base, which, however, soon lose their most characteristic properties. As native sulphur is frequently met with in yellow crystals, whose form is derived from the octahedron with a rhombic base, it is obviously a dimorphous substance.

It has been already stated that sulphur fuses at 239°; from that temperature up to 280°, it forms a yellow, transparent, limpid liquid; as the heat increases, the color becomes brown, and almost black, and the liquid becomes viscid, these changes being very distinctly seen at 350°. If the external application of heat be steadily continued, it will be found that for a while the temperature remains constant, but it afterwards rises, and at nearly 500°, the sulphur again liquefies, although less completely than when first melted. If it be now suddenly cooled by pouring it, in a slender stream, into cold water, we obtain a spongy, tenacious, and plastic mass, which may be drawn out into elastic threads, whose color, after they have cooled, varies from an amber to a deep brown color, according to the heat that has been employed. After some hours, the ductile sulphur loses its characteristic properties, increases in density, and returns to the brittle form; or, if it be heated to 212°, it suddenly returns to the brittle condition; the temperature rising to 230° during the change. Hence, sulphur may be obtained in three (if not in more) allotropic states, which are distinguished by the symbols $S\alpha$, $S\beta$, $S\gamma$. The first variety, $S\alpha$, is the native octahedral crystal of sulphur (*a*); it may be obtained artificially by dissolving sulphur in bisulphide of carbon, or chloride of sulphur, and submitting the solution to spontaneous evaporation. These crystals are semi-transparent, of an amber-yellow color, and undergo no change on exposure to the air. The second variety, $S\beta$, is the oblique prismatic crystal already described as being formed when fused sulphur cools slowly. The best method of obtaining these crystals is to melt a few pounds of sulphur, and allow it to solidify on the surface. On perforating the external crust with a hot wire, and pouring out the sulphur that remains liquid, the interior of the cavity is found to be traversed in all directions by these crystals (*b*), occurring as transparent brownish needles, having a specific gravity considerably less even than that of roll-sulphur. On exposure to the air, they soon lose their coherence, and form an opaque and crumbling mass, consisting of minute rhombic octahedra. This conversion of the prismatic into the octahedral form takes place immediately, if the prisms are immersed in bisulphide of carbon.



The third variety, S., is the plastic amorphous sulphur, which has been sufficiently described. If sulphur be frequently heated to 600°, and suddenly cooled, a black variety of this element is produced; and a red variety has been obtained, but the redness is now supposed to be due to the presence of a trace of some fatty body.

Sulphur is a bad conductor of heat, and the mere heat of a warm hand often causes it to crackle, and even to fall to pieces, from the unequal expansion. It is an insulator of electricity, and becomes negatively electric by friction. It is slightly soluble in alcohol, ether, and the fatty oils; its best solvents being the bisulphide of carbon and chloride of sulphur. When it is heated in the air, it takes fire at about 470°, burning with a blue flame, and becoming converted into sulphurous acid, whose pungent suffocating fumes are characteristic of sulphur. This element is second only to oxygen in its powerful affinity for other elements, with most of which it unites, and often in several proportions. With most of the metals it combines very readily, and in some cases, with a development of light and heat; thus, silver and copper burn in sulphur-vapor just as iron-wire or zinc-foil burns in oxygen. In consequence of its power, with the aid of heat, of forming sulphurous acid with the oxygen of the air, and thus rendering the latter incapable of supporting combustion, burning sulphur may be usefully employed for the extinguishing of fire—as, for example, in chimneys.

Sulphur occurs very widely distributed in the mineral kingdom, partly free and partly combined with other elements. The free sulphur is either found pure in regularly formed crystals, or intimately mixed with earthy matters. The principal sources of crystalline sulphur are Urbino in Italy, Girgenti in Sicily, and Radoboy in Croatia; while the earthy sulphur is mainly derived from Italy, Moravia, and Poland. Iceland is rich in both varieties, but the mineral wealth of that island remains almost unworked. At present, by far the greatest quantity of the sulphur employed in Europe comes from Sicily; and, as a general rule, it is abundant in volcanic districts. In the form of sulphide, sulphur occurs abundantly in combination with iron, copper (iron and copper pyrites), lead (galena), zinc (blende), &c., the bisulphide of iron (or iron pyrites) furnishing most of the sulphur that is employed in the manufacture of sulphuric acid. Sulphur is still more extensively distributed in the form of sulphates, the sulphates of lime, magnesia, baryta, &c., being abundant natural productions. In the vegetable kingdom, sulphur is a constituent (although only to a small amount) of the albuminous bodies which are so widely diffused in plants; and of certain volatile irritant oils, as those of mustard, garlic, asafœtida, &c.; and, moreover, the vegetable juices contain it in the form of certain sulphates. In the animal kingdom, it is not only a constituent of the albuminous, fibrinous, and gelatinous tissues, but of the hair, saliva, bile, urine, &c. The two animal substances in which it is most abundant are Cystin (q. v.), an occasional constituent of urinary calculi, and Taurine (q. v.), a constituent of the bile, in both of which it forms about a quarter of the entire weight.

It would be out of place in this article to enter into details regarding the *extraction* or *preparation* of sulphur. It is sufficient to state that the grosser impurities are removed by crude processes of fusion and distillation at or near the place from whence it is obtained. That which is imported into Britain undergoes further purification. What is called *refined sulphur* is that purified by distillation in a large cast-iron still, and condensed in a receiver kept cool. When the vaporized sulphur is condensed in a large chamber, it is obtained in the form of *sublimed sulphur*, or *flowers of sulphur;* but as the walls get hot it melts and collects on the floor, and is run into cylindrical wooden moulds, from which, when cool, it is taken out as *roll* or *stick sulphur*. The residue left in the retort is a mixture of sulphur with various impurities. Under the names of *Black Sulphur*, or *Sulphur vivum* (commonly inquired for at the chemist's under the title of *Sulphur of Ivy*), it is used in veterinary medicine, and for the purpose of dressing mouldy hops. Sulphur is thrown down from certain of its compounds (as from a strong solution of a polysulphide of calcium, sodium, or potassium) by dilute hydrochloric acid; it falls as a grayish-white, very fine, light powder, known in the Materia Medica as *milk of sulphur*, or *precipitated sulphur*. For the method of obtaining sulphur from iron pyrites, we must refer the reader to Miller's *Inorganic Chemistry*, 2d ed. p. 154. The proceeding is usually conducted on a large scale, 2000 tons of pyrites being roasted at once, the roasting extending over five or six months, and the final result being about 20 tons of sulphur. The most common impurities met with in ordinary commercial sulphur are selenium and realgar (bisulphide of arsenic). Flowers of sulphur frequently exhibit a slight acid reaction, in consequence of a little sulphurous acid clinging to them. By rinsing them with water, this impurity is at once removed.

Sulphur is extensively employed in the arts and manufactures; as in the manufacture of matches, gunpowder, &c. When converted into sulphurous acid, it is employed as a powerful bleaching agent, and also for the destruction of insects, fungi, &c.; but its chief consumption is in the manufacture of sulphuric acid.

The compounds of sulphur and oxygen are no less than seven in number, all of which present the character of acids. These acids have the following composition :

		Sulphur.		Oxygen.
Sulphurous acid	SO_2	16	:	16
Sulphuric acid	SO_3	16	:	24
Hyposulphurous acid	S_2O_2	32	:	16
Hyposulphuric acid	S_2O_5	32	:	40
Trithionic acid	S_3O_5	48	:	40
Tetrathionic acid	S_4O_5	64	:	40
Pentathionic acid	S_5O_5	80	:	40

The last five of these acids have never been obtained in the anhy-

drous form. We shall only notice the most important members of this group, viz., the first three of them, and of these, the second, *Sulphuric Acid*, is so extremely important, that it is discussed in a special article. (The last three derive the essential portion of their name from the Greek word *theion*, sulphur.)

SULPHUROUS ACID or SULPHUROUS ANHYDRIDE (SO_2), occurs under the ordinary relations of temperature and pressure as a colorless gas, possessing the suffocating odor of burning sulphur. In its concentrated form, it is quite irrespirable, and in a diluted state it excites cough, and produces the symptoms of an ordinary catarrh. It is not only incapable of burning, but it rapidly extinguishes the flame of burning bodies. It is very freely soluble in cold water, which at 32° takes up nearly 69 times its volume of the gas, while at 75° it only takes up 32 volumes; the solution known as *Aqueous Sulphurous Acid* having at first the same smell and taste as the gas, but soon absorbing oxygen from the air, and becoming converted into sulphuric acid. By the action of cold, sulphurous acid may be condensed to a colorless transparent limpid liquid, which freezes at —105°, forming a transparent crystalline solid.

The specific gravity of the gas is 2·247 (atmospheric air being the unit), and that of the liquid is 1·49 (water being the unit), the solid being considerably heavier. Although dry sulphurous acid gas and dry oxygen, when mixed, exert no action on one another, there are many conditions under which sulphurous acid rapidly absorbs oxygen, and is converted into sulphuric acid. It has been mentioned that this takes place if the gas be dissolved in water; a similar action takes place under the influence of hydrated nitric acid, iodic acid, and certain metallic oxides. For example, oxide of lead, when immersed in the gas, burns and is converted into white sulphate of lead ($PbO_2 + SO_2 = PbO,SO_3$). Hence, sulphurous acid is a powerful reducing or deoxidizing agent. This gas is a common and abundant product of volcanic action, and is occasionally met with in solution in the springs in volcanic regions. It may be prepared artificially by simply burning sulphur in the air or in oxygen gas, or by heating in a flask 4 parts of flowers of sulphur mixed with 5 parts of powdered black manganese, sulphurous acid and sulphide of manganese being the products, as shown by the equation $2S + MnO_2 = SO_2 + MnS$. In consequence of its solubility in water, this gas should be collected over mercury. In addition to the uses of sulphurous acid as a bleaching agent, it is valuable both as a disinfectant agent and as a powerful antiseptic; its latter property has been applied to the preservation of meat, which, after exposure to this acid, will keep fresh for years, if it be enclosed in metallic canisters filled with nitrogen, to which a little binoxide of nitrogen has been added, to remove any trace of oxygen. But by far its most important use is, as a first stage in the manufacture of sulphuric acid. In combination with bases, this acid forms the *sulphites*—a class of salts which, excepting the sulphite of soda, are of little practical importance, except for their power, when moist, of extracting oxygen, and thus acting as reducing agents. For example, the salts of the sesquioxide of iron are reduced by them to salts of the protoxide.

HYPOSULPHUROUS ACID (S_2O_2) as yet is only known in a state of combination with bases; for on attempting to separate the acid from the base, the former becomes decomposed into sulphur and sulphurous acid. The most important of its salts is the *Hyposulphite of Soda* ($NaO,S_2O_2 + 5Aq$), whose mode of preparation and characters are described in the article SODIUM. This and other soluble hyposulphites may be easily recognized by the facility with which they dissolve the haloid salts of silver, forming a solution of an extremely sweet taste, and containing a double hyposulphite of silver and soda, with an admixture of chloride, iodide, or bromide of sodium. It is this power of dissolving those salts of silver which are insoluble in water, that renders the hyposulphite of soda so important an agent in photography. The only other salt of this acid which we shall notice is the *Hyposulphite of Gold and Soda* [$AuO,S_2O_2,3(NaO,S_2O_2) + 4Aq$] which may be prepared by mixing concentrated solutions of 1 part of chloride of gold and 3 parts of hyposulphite of soda, and adding alcohol, when the required salt is precipitated. It is used for gilding the daguerreotype plate, and for coloring the positive proof obtained in photographic printing.

With hydrogen, sulphur forms two compounds, viz., *Sulphuretted Hydrogen*, or *Hydrosulphuric Acid* (q. v.), and *Persulphide of Hydrogen*, an oily liquid, having the smell and taste of sulphuretted hydrogen, and in many of its properties having an analogy to binoxide of hydrogen. Sulphur combines with carbon to form a *Bisulphide of Carbon* (CS_2), a very volatile colorless liquid, of a high refractive power, of an acrid and pungent taste, and a very disagreeable odor. It is heavier than water, in which it is insoluble, but dissolves freely in alcohol and ether, and is the best solvent for sulphur and phosphorus. Bisulphide of carbon does not occur as a natural product, but may be obtained by heating fragments of charcoal to bright redness in a porcelain tube, and passing sulphur vapor along it. Its vapor, when freely inhaled, exerts a similar anæsthetic action with those of chloroform and ether. Workmen in caoutchouc or other manufactures in which bisulphide of carbon is used as a solvent, suffer very much from prolonged exposure to its vapor, which produces headache, loss of appetite, impairment of vision and hearing, and causes general derangement of health by its deleterious action on the nervous system. Sulphur combines with chlorine in several proportions, the most important of these compounds being the *Subchloride of Sulphur* (S_2Cl) and the *Chloride of Sulphur* (SCl). Both of them are liquids, and are formed by the direct action of the combining elements. The subchloride is a yellow volatile liquid with a penetrating and disagreeable odor. When dropped in water, it sinks to the bottom (its spec. grav. being about 1·687), and is slowly decomposed into hydrochloric and various sulphur acids, and free sulphur. It is capable of dissolving about 67 per cent. of sulphur at an ordinary temperature, and, like bisulphide of carbon, is extensively employed in vulcanizing india-rubber. The chloride of sulphur is formed by saturating the subchloride with chlorine. It is a deep red liquid, resembling the previous compound in most of its properties. It is decomposed by the sun's rays into the subchloride and free chlorine.

With regard to the history of sulphur and its compounds, it may be observed that sulphur seems to have been known from the earliest times, and that sulphuric acid was most probably known to the Arabians. The manufacture of English sulphuric acid dates, however, only from the 18th century. Sulphurous acid was first investigated by Stahl, Scheele, and Priestley; hyposulphuric acid was discovered by Welter and Gay-Lussac; hyposulphurous acid, by Gay-Lussac and Herschel; trithionic acid, by Langlois; tetrathionic acid, by Fordos and Gelis; and pentathionic acid, by Wackenroder. Scheele was the first who accurately studied hydrosulphuric acid, or sulphuretted hydrogen.

Sulphur is used to a considerable extent and for very different purposes in medicine. It is given internally either as sublimed sulphur (flowers of sulphur) or as precipitated sulphur (milk of sulphur), in somewhat large doses, as a mild cathartic—its purgative effects being due to its stimulating the muscular coat of the intestines. In consequence of its being both gentle and sure in its action, it is the best purgative to employ in cases of piles or in stricture or other painful affections of the rectum. The only objection to its use is that, from its becoming partly converted in the system into sulphuretted hydrogen, the evacuations, and even the insensible perspiration, often become abominably fœtid, and continue so for some time after the primary operation of the medicine. As a purgative, the dose is about two drachms, made into an electuary with treacle or honey. It is, however, generally combined with jalap and cream of tartar.

The *Confection of Sulphur* of the Pharmacopœia is composed of sulphur, cream of tartar, and syrup of orange-peel rubbed together—the dose being from half an ounce to an ounce, or from one to two tablespoonfuls. In small doses, sulphur is of great value in cases of atonic gout and chronic rheumatism. An electuary known as *The Chelsea Pensioner*, consisting of two ounces of sublimed sulphur, one ounce of powdered rhubarb, half an ounce of resin of guaiacum, one ounce of cream of tartar, half an ounce of ginger, and two drachms of powdered nutmegs, with as much treacle as is necessary, in doses of one or two teaspoonfuls night and morning, is a combination of great value in these cases. It originally gained its reputation by curing Lord Amherst of rheumatism, and is still a favorite remedy at Chelsea Hospital. Dr. Neligan states that steaming the lower bowel, by sitting over the vapor of warm water upon which a tablespoonful of flowers of sulphur had been sprinkled, constitutes a most valuable remedy in what is popularly known as a 'fit of the piles.' The external use of sulpher in the form of ointment has been already noticed in the article ITCH. It is also used externally in many other cutaneous disorders, particularly in lepra and psoriasis; and in chronic cases, its application in the form of vapor is often of great service.

SULPHU'RIC ACID, or, more correctly, Hydrated Sulphuric Acid (SO_3,HO), is the chemical name of the liquid commercially and properly known as *Oil of Vitriol*.* It is a dense, colorless, oily liquid, without smell, of a spec. grav. of 1·846 at a temperature of 60°, and of an intensely acid taste and reaction. It has a powerful caustic action, and chars and destroys organic matters for its strong affinity for water; and in consequence of this destructive property, it must always be handled with the greatest caution. So powerful is this affinity, that if the acid be exposed for a few days to the air in a shallow dish, so as to present a large surface, it often doubles its weight by absorbing aqueous vapor from the air; and in consequence of its possessing this property, it is extensively used in laboratory operations as a desiccating agent. It mixes completely with water in all proportions, and as great heat is given out at the moment of mixture, the dilu-

* It received this name from having been first produced by the distillation of green vitriol (sulphate of iron); Basil Valentine being usually credited with the discovery. See ALCHEMY.

tion should be performed by very gradually adding the acid to the water. When cold, the mixture occupies less bulk than the two components previously occupied. This acid freezes at a temperature of —15°, and boils at 620° (or according to Marignac, at 640°), and just above the boiling-point, it assumes the form of a vapor, with a spec. grav. of 2·15. Oil of vitriol, or the protohydrate, is not the only hydrate of sulphuric acid. Three others are known to exist. When the fuming oil of vitriol of Nordhausen is exposed to a low temperature, a white crystalline substance separates, which is a hydrate, containing half as much water as the common liquid acid.

Its formula is $2SO_3.HO$, or $(SO_3)_2HO$. Its fusing-point is 95°. Then, again, a mixture of 49 parts of the strong liquid acid and 9 parts of water ($SO_3,2HO$) freezes at 47°, and crystallizes into splendid rhombic prisms, from which property it is often termed *glacial sulphuric acid*. It boils at 435°, and its spec. grav. is 1·780. Lastly, when a very dilute acid is concentrated by evaporation *in vacuo*, at 212°, till it ceases to lose weight, there will be a resulting compound, consisting of 40 parts of the real acid, and 27 of water, and represented by the formula, $SO_3,3HO$. It boils at 348°, and its spec. grav. is 1·602. There are thus no less than four hydrates of sulphuric acid—viz. (1) the dihydrate, $2SO_3.HO$; (2) the ordinary protohydrate, $SO_3.HO$; (3) the bihydride, $SO_3.2HO$; and (4) the terhydrate $SO_3,3HO$. The compound formerly known as *anhydrous sulphuric acid* possess none of the characteristic properties of an acid. See SULPHURIC ANHYDRIDE; also CHEMISTRY.

Sulphuric acid in its free state is a very rare natural product; although, in combination with bases, it is common in the animal and vegetable, and abundant in the inorganic kingdom. The only cases in which it is known to occur free are certain American rivers, especially the Rio Vinagre, and some lakes in Tennessee and in Java; and it has been found to be a normal constituent of the saliva of *Dolium galia*, a species of snail found in Sicily. In all these cases, the acid is, of course, in an extremely diluted form. In plants, it exists in the juices, and in animals in the blood and its derivates chiefly in the form of sulphates of the alkalies; while in the mineral kingdom it occurs as gypsum (sulphate of lime), heavy spar (sulphate of baryta), celestine (sulphate of strontia), &c.

Sulphuric acid may be prepared on a small scale by boiling sulphur in *aqua regia*, or in nitric acid, the sulphur becoming gradually oxidized into sulphuric acid. As a general rule, however, the commercial acid is employed even for laboratory experiments. See below.

In order to obtain the acid in a pure form, suitable for medical use or medico-legal analyses, it must be redistilled with sulphate of ammonia in a retort containing a few slips of platinum foil, the first and last portions being rejected. The distillation is attended with violent concussions, partly owing to the high specific gravity of the acid, and partly owing to its high boiling-point, and this convulsive action is moderated mechanically by the platinum slips. Sulphuric acid thus prepared according to the directions of the British Pharmacopœia may be regarded as perfectly pure, presuming arsenic is not present. Strong sulphuric acid has comparatively little action on the metals except at a high temperature, when it dissolves them, and, at the same time, undergoes partial decomposition; the metal being oxidized by a portion of the acid which becomes decomposed into oxygen and sulphurous acid, and then uniting with a portion of undecomposed acid to form a sulphate. Silver, copper, mercury, arsenic, antimony, bismuth, tin, lead, and tellurium are thus acted on. Gold, platinum, rhodium, and iridium are not affected by the acid even at a boiling temperature. The more oxidisable metals, such as zinc, iron, nickel, and manganese, are readily soluble in the dilute acid, water being decomposed, and hydrogen liberated, while the oxygen of the water unites with the metal; and the metallic oxide, at the moment of its formation, combines with the sulphuric acid to form a sulphate.

The *sulphates*—or salts formed by the combination of sulphuric acid with a base—are generally composed, as in the case of green vitriol (FeO,SO_3+7Aq), of 1 equivalent of acid and 1 of metallic oxide, with or without water of crystallization. With the alkalies, this acid also forms acid salts, as bisulphate of potash, and in a few cases, copper, for example, it forms basic salts. The insoluble sulphates, such as that of baryta, may be obtained by precipitating a soluble salt of the base by a soluble sulphate; thus, nitrate of baryta and sulphate of soda yield an insoluble sulphate of baryta and nitrate of soda, which remains in solution. The soluble sulphates may be prepared by dissolving the oxide or carbonate in dilute sulphuric acid, in those cases in which the metal itself is not readily attacked by the acid. Sulphuric acid and the soluble sulphates are easily detected by their yielding, with a solution of a baryta salt, a white precipitate of sulphate of baryta insoluble in acids.

This acid is employed in the arts and manufactures for a large number of purposes. Its use as a desiccating agent for laboratory purposes has been already noticed, and its application to the development of oxygen gas has been described in the article on that element. But its greatest consumption, doubtless, is in the preparation of the *Salt-cake*, which is used in the manufacture of Carbonate of Soda (q. v).

In medicine, a *dilute sulphuric acid*, formed by gradually mixing three fluid ounces of the strong purified acid with thirty-five fluid ounces of water, or *aromatic sulphuric acid* (known also as *elixir of vitriol*), prepared by mixing three ounces of sulphuric acid with a quart of rectified spirit, adding cinnamon and ginger, digesting for a week, and filtering, are almost always employed. In doses of from ten to thirty minims, properly diluted, these preparations exert a strong astringent power, and are serviceable in all forms of passive hæmorrhages, and in checking inordinate discharges when they arise from debility. In ordinary diarrhœa, and even in the premonitory diarrhœa of cholera, dilute sulphuric acid is of great use. In painters' colic, it is given in order to convert any lead that is absorbed into an insoluble sulphate, which is inert. Sulphuric acid lemonade is also used as a prophylactic against the disease. As this acid exerts a deleterious action on the teeth, it should be directed to suck it through a quill. In some cases, it is prescribed not so much for its specific as for its solvent power; with this object, it is usually prescribed with quinia. The strong acid is used in surgery as a caustic. In cases of *poisoning* with this acid, the most prominent features are: burning pain extending from the mouth to the stomach, intense pain in the bowels, vomiting, great prostration, coldness of the surface, and fœtor of the breath. The mucous membrane of the parts injured by the acid is at first converted into a white slough, which soon becomes black, and the patient usually dies from exhaustion within twenty-four hours. The best antidotes are the alkaline bicarbonates, or carbonate of magnesia. If the primary symptoms be conquered, the patient often dies subsequently from stricture of the œsophagus.

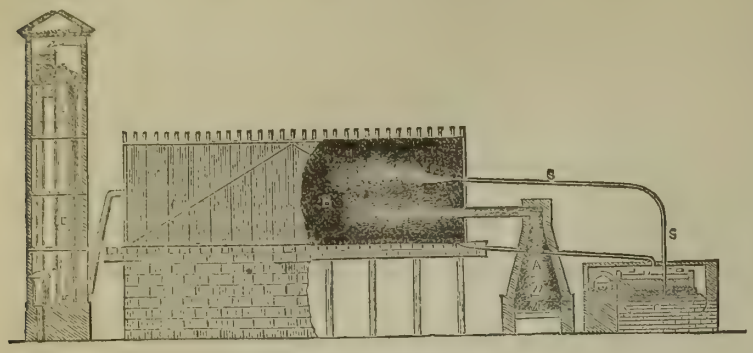
Sulphuric Acid Manufacture.—There are two distinct processes by which sulphuric acid is at present prepared on a large scale—viz., by the distillation of green sulphate of iron—the original process of Valentine; and by the oxidation of sulphurous acid through the agency of nitrous acid and hyponitric acid. The first process is chiefly employed at Nordhausen, in Prussia, and is thus described by Fownes: 'The sulphate of iron, derived from the oxidation of iron pyrites, is deprived by heat of the greater part of its water of crystallization, and subjected to a high heat in earthern retorts, to which receivers are added as soon as the acid begins to distil over. A part gets decomposed by the very high temperature; the remainder is driven off in vapor, which is condensed by the cold vessel containing a very small quantity of water or common sulphuric acid. The product is a brown oily liquid of about 1·9 specific gravity, fuming in the air, and very corrosive. It is chiefly used for the purpose of dissolving indigo.'

The second method is that universally followed in Great Britain, the germs of which were likewise discovered by Valentine. He observed that when the fumes of burning sulphur were collected under a bell jar, slightly moistened with water, a small quantity of liquid was deposited. This liquid, which was simply sulphuric acid, on being concentrated from its solution by boiling, was long sold as oil of sulphur *per campanum* at prices as high as 2*s*. 6*d*. per ounce.

About the year 1740, the French chemists Lefevre and Lemery suggested that, by the use of nitre along with the sulphur, the operation might be conducted in close vessels, and a much greater quantity of acid might be produced. This idea was acted on in England by a Dr. Ward, who established works at Twickenham and Richmond, conducting his manufacture by burning the mixed sulphur and nitre in large stoppered glass receivers, into each of which a small quantity of water was first introduced. The substitution, by Dr. Roebuck of Birmingham, of lead chambers in place of the glass vessels, may be regarded as essentially the establishment of the process of manufacture followed at the present day. Dr. Roebuck established his first works at Prestonpans in 1749.

The first stage in the manufacture of sulphuric acid is the preparation of sulphurous acid by the burning of sulphur or of iron pyrites. Previous to the year 1838, Sicilian sulphur was almost exclusively used in the manufacture, but in that year, the very ill-advised establishment of a monopoly of the sulphur trade by the Sicilian government, and its consequent increase in price, diverted the minds of manufacturers to the employment of iron pyrites (sulphuret of iron), the use of which, as a source of sulphurous acid, was already not unknown. The monopoly was quickly abolished, on the representations of the English government, but not until it was demonstrated that the world was independent of Sicily both for sulphuric acid and sulphur. Iron pyrites is now much more used than sulphur, and the only hindrance to its universal adoption is the presence of foreign matter in the pyrites, the most deleterious being arsenical compounds; and it has hitherto been found impracticable to free the sulphuric acid wholly from the arsenious acid which consequently accompanies it. This renders the acid prepared from pyrites inapplicable for many purposes.

When sulphate is the material used for producing the sulphurous acid, it is burned in an oven or 'burner' (A) of brickwork, having a sole or bottom of iron, termed the 'burner-plate.' Under this, a small fire is at first lighted, which is allowed to go



Manufacture of Sulphuric Acid:
A, sulphur-burner, or furnace; B, lead chamber, shown in section at B'; C, steam boiler; D, leaden pan; E, coke tower; S, steam-pipe; *n*, niter pot.

out after the sulphur has ignited. A little above the sulphur, a small pot, called the niter pot, *n*, is either placed on a stand, or hung from the roof, filled with a quantity of either nitrate of soda or nitrate of potash, with sulphuric acid sufficient for its decomposition—8 or 10 lbs. of the niter, with 5 or 6 lbs. of sulphuric acid, being allowed for every cwt. of sulphur. The decomposition of the niter by the heated sulphuric acid, furnishes nitric acid fumes, which go over into the chamber along with the sulphurous acid. The sulphurous readily abstracts from the nictric acid the additional equivalent of oxygen required for its conversion into sulphuric acid, reducing the nitrous compound from nitric acid, NO_5, to nitrous oxide NO_2; the reaction being thus—$3SO_2 + NO_5 = 3SO_3 + NO_2$. Nitrous oxide in its turn quickly converts itself into nitrous acid, NO_4, by the abstraction of two additional equivalents of oxygen from the air that is constantly entering the chamber through the burners. Again, in the presence of moisture which is supplied by a jet of steam from the boiler C, sulphurous acid readily deprives the nitrous acid of two equivalents of oxygen, and thus forms two more volumes of sulphuric acid, and again liberates nitrous oxide; which is ready once more to seize upon the oxygen of the air, and would continue so acting and reacting *ad infinitum*, were it not carried forward and out by the chimney provided for the escape of the freed nitrogen.

The chamber is an immense box or room of lead, bound together with a strong framework of timber, and generally raised on arches several feet above the ground. Chambers vary in size from 60 to 140 feet in length, and from 20 to 40 feet in width and height. Curtains of lead proceeding alternately from the bottom to near the top, and *vice versâ*, are very frequently used; they serve to retard the progress of the gases, and thus insure the transformations desired. The floor of the chamber is covered with water, into which the sulphuric acid falls as it is formed; and when this solution attains a certain strength, it is tapped off for concentration. When the gases reach the chimney, on account of the reactions of the nitrous compounds already explained, a large amount of nitrous acid would not only be wasted, but would also be deleterious to the neighborhood, were steps for its recovery not adopted. This recovery is usually effected by means of a tower filled with coke, E, down which a constant stream of strong sulphuric acid trickles, the acid absorbing the nitrous fumes in their way upwards. Instead of a single chamber, curtained off or not as the case may be, sometimes three or five distinct chambers, connected by pipes, are employed, those communicating directly with the burners being termed working chambers, and the others receiving chambers, the last either acting as or communicating with a condenser or chimney.

When iron pyrites is used as the source of sulphurous acid, suitable burners are used. In England these are arched chambers about four feet each way, on plan with furnace-bars placed a little above the ground. There are also the necessary doors and air-holes. The pyrites is broken into pieces, and spread in layers on the bars, which are previously heated to redness, and the heat evolved by the burning sulphur is thereafter sufficient fuel for the fresh charges. The exhausted ore is frequently sufficiently rich in copper for its extraction; indeed, when there is not more than 2½ per cent. present in pyrites, it is now recovered.

In consequence of strong sulphuric acid absorbing both sulphurous acid and nitrous acid, the acid requires to be drained off from the chamber while the solution is comparatively weak, at which strength, viz., of a specific gravity of about 1·4, it is used for some purposes in the arts, under the name of 'Chamber Acid.' This is concentrated by evaporating, in lead pans, D, till it reaches the specific gravity of 1·6, then boiling in a platinum retort, on which strong acid does not act, even at high heat, or in large flint-glass retorts.

An important improvement has recently been introduced into the manufacture of sulphuric acid, by Mr. W. Glover of New-castle-on-Tyne. Instead of conducting the gaseous sulphurous acid from the sulphur or pyrites burners direct to the lead chamber, it is first passed through a 'Glover' or 'denitrating tower,' which nearly resembles in form and size the 'coke-tower' shown in the figure. This is packed openly with fire-brick or flints. On the top of it are placed two cisterns, one containing strong nitrated sulphuric acid from the coke-tower, and the other, the weaker 'Chamber Acid.' Both of these are allowed to flow down through the flints, and thus mixing, the strong acid becomes too weak to retain the dissolved nitrous fumes. As these fumes separate, they are carried away with the sulphurous gas from the pyrites burners into the lead chambers. By the use of the 'Glover tower,' the sulphuric acid is purified of nitrogen compounds; these are saved for use in the lead chamber; and the 'Chamber Acid' is concentrated to about 1·75 specific gravity, without the use of lead pans and coal.

The manufacture of sulphuric acid is a very extensive industry; immense quantities of it being consumed in the manufacture of soda, in that of bleaching-powder, in calico-printing and dyeing, and, in fact, in most chemical operations both in the manufactory and the laboratory. See Lunge's *Manufacture of S. A. and the Alkalies* (3 vols. 1879–81).

SULPHURIC ANHYDRIDE, formerly known as ANHYDROUS SULPHURIC ACID, is commonly represented by the formula SO_3, but there are good reasons for believing that it is a compound of two atoms of sulphur with six of oxygen. It is a colorless crystalline solid, which is tough and ductile, and can be moulded in the fingers like wax without injuring the skin. It liquefies at 65°, and boils at about 112°, forming a transparent vapor, if hot water be present. It unites with moisture when exposed to the air, and gives off dense white fumes. When thrown into water, the heat emitted is so great that it hisses as red-hot iron would do; and the solution has all the properties of ordinary sulphuric acid. It may be obtained by the distillation of fuming Nordhausen acid, when white fumes pass over in the cooled receiver, and solidify into a white silky-looking fibrous mass. It may be also obtained by the distillation of acid sulphate of soda ($NaO,HO,2SO_3$), after it has been deprived of its atom of water. It combines with sulphur, iodine, and hydrochloric acid; but both it and its compounds are of chemical interest rather than practical value. See CHEMISTRY.

SULPHURIC ETHER is a term commonly but improperly applied to ethylic, vinic, or ordinary Ether (q. v.). True *sulphuric ether*, known also as *sulphate of ethyl* ($2C_4H_5O,S_2O_5$), is an oily liquid, of burning taste and ethereal odor, resembling that of peppermint, of specific gravity 1·120 (while that of ordinary pure ether is 0·720), and almost incapable of being distilled without decomposition, as at a temperature of about 280° it resolves itself into alcohol, sulphurous acid, and olefiant gas.

In the article ETHER, reference is made to the anæsthetic properties of that compound. Dr. Richardson has discovered that local insensibility may be readily induced by the application to the skin of the finely divided spray of perfectly pure rectified ether, of specific gravity 0.723. The skin blanches in from half a minute to two minutes; and by following the knife with the spray, more than merely superficial incisions may be rendered painless. It has been successfully employed in amputations of fingers and toes, removal of tumors, opening of abscesses, removal of teeth, &c.

SU'LPHUROUS ACID some years ago became one of the most popular articles in our Pharmacopœia. This sudden popularity was mainly due to the researches of a Scottish provincial physician, Dr. Dewar of Kircaldy, who, from beginning his experiments on cattle during the period of the cattle-plague of 1866, extended them to other animals and to man, and obtained remarkably satisfactory results (see *Medical Times and Gazette* for 1867, vol. i., pp. 492, 548). There is, of course, nothing new in applying sulphur-fumes—which in reality are composed of suphurous acid gas—as a disinfectant. The classical scholar will recollect that Ulysses employed them to remove the unpleasant smell arising from the dead bodies of Penelope's murdered lovers. 'Bring brimstone, the relief of evils,' he exclaims, 'and bring me fire that I may sulphurize the house.'—Hom. *Od.* xx. 481, 482. It is also recorded by Ovid (*Fasti*, iv. 735) and other writers that the shepherds of Italy yearly purified their flocks and herds with 'the blue smoke of burning sulphur.' Professor Graham's remark, that of gaseous disinfectants, sulphurous acid (obtained by burning sulphur) is preferable, on theoretical grounds, to chlorine, and that no agent checks so effectually the first development of animal and vegetable life,

may be said to contain all that was known with regard to the medicinal value of this gas, till Dr. Dewar began his investigations. In his experiments in connection with the cattle-plague, he found that the most safe and convenient apparatus consists of a chafer two-thirds full of *red* cinders, a crucible inserted in the cinders, and a piece of sulphur-stick. A piece of sulphur as large as a man's thumb will burn for nearly twenty minutes, and will suffice for a cow-house containing six animals; and it appears undoubted that if there be due ventilation, this process may be performed four times a day for at least four months with positive advantage to the animals.

When this system had been efficiently carried out—and it has been largely tried by his friends—no case of illness, not to say of death, occurred. In Mr. Crookes's Report *On the Application of Disinfectants in arresting the Spread of the Cattle-plague*, that able chemist observed that 'the value of sulphurous acid in arresting the progress of the cattle-plague has been proved beyond a doubt by the experiments of Dr. Dewar, and my own results entirely confirm his.' His experiments in relation to the cattle-plague led Dr. Dewar to the further discovery of the value of sulpur fumigation in other departments of veterinary medicine. Peripneumonia, ringworm, mange, are amongst the diseases which rapidly disappear under its influence; and in the sudden undefined illnesses known in Scotland as 'drows' and 'towts,' to which most of our domestic animals are liable, sulphurous fumigation, if applied at the outset, rarely fails to cut short the attack.

In medical practice, there are three different forms, independently of the sulphites, in which sulphurous acid may be employed—viz. (1) As the sulphurous acid of the British Pharmacopœia, which contains 9·2 per cent. by weight, or about twenty times the volume of sulphurous acid gas dissolved in water; (2) in the form of spray, which escapes from the preceding compound under the action of an apparatus called a Spray-producer; and (3) as a gas evolved by sprinkling at intervals small quantities of 'flowers of sulphur' on red-hot cinders placed on a common shovel, resting on a stool in the middle of the room, or by burning bisulphide of carbon (*Lancet* for 1876, vol. ii., pp. 712, 811). A mixture of equal parts of sulphurous acid and water has been recommended in all cases of 'breaches of the skin,' as primary wounds (whether resulting from injuries or surgical operations), in ulcers, burns, bed-sores, chapped hands, chilblains, saddle-sores (whether of man or beast), sore nipples, and in cases of bruises, such as black-eye, &c. Moreover, in erysipelas, its soothing properties, if diluted with two or three parts of water, are very striking.

According to Dr. Dewar, the feverish irritability of young children is speedily relieved by dropping from time to time a few minims (5 to 30, according to age) of the acid on a few folds of muslin fastened on the breast: here, however, the action is not local, but is due to the evolution of the gas which is inhaled. Amongst the cases in which the acid is serviceable, when applied in the form of spray or inhaled as gas, are asthma, bronchitis, catarrh, croup, diphtheria, facial neuralgia, laryngeal affections, phthisis (at all events as a palliative), scarlatina, and typhoid. Dr. Dewar ascribes the healing action of sulphurous acid to its power of destroying fungi. That the acid has this power, we freely admit, but we cannot so readily admit the correctness of his view that all the diseases in which he has found it serviceable (including piles and chilblains) are dependent on fungous growths. Dr. Dewar reports a case of severe sciatica, in which immediate and perfect relief was afforded by the injection of an ounce of sulphurous acid in a breakfast-cupful of gruel into the rectum. There is one affection of this class, to which Dr. Dewar does not refer, in which it has been prescribed with advantage—viz., the form of gastric disorder in which *Sarcina Ventriculi* (q. v.) occurs in the vomited matter, the dose being half a drachm, largely diluted with water.

None of the *sulphites* or *hyposulphites* have as yet been introduced into the Pharmacopœia. We notice them here because their action is supposed to depend upon the liberation of sulphurous or hyposulphurous acid when the salt comes in contact with the acid juices of the stomach. It is mainly to Dr. Polli that we are indebted for the introduction of the sulphites and hyposulphites of the alkalies and alkaline earths (soda, potash, and magnesia) into medicine. From the year 1857 onwards, he for several years devoted almost all his time to the study of these agents. His labors are briefly summed up as follows by Dr. Sanson in an excellent Memoir on 'The Germs of Cholera, and the Means of their Destruction,' published January 22, 1868, in the *Medical Press and Circular*: 'It was found that animals could, without any apparent ill effects, swallow and absorb large doses of the sulphites. It was then observed that when the animals were killed, they long resisted the putrefactive process. Another series of experiments—and in this series 300 dogs were the basis of the deductions—showed that the sulphites exerted a prophylactic and curative power when septic poisons were introduced into the economy. Then, as regards the human subject, it was found that the stomach would tolerate large doses of the sulphites of soda or magnesia. They were tried in the various eruptive fevers, intermittent, diphtheria, typhus, typhoid, cholera and choleraic diarrhœa, pyæmia, puerperal fever, dissection wounds, malarial infection, &c. The records of cases treated in this way show an extraordinary amount of success.'

In a paper published by Dr. Polli himself in *The British Medical Journal* for November 16, 1867, he states that since the promulgation, in 1861, of his views regarding the therapeutic value of the sulphites, no less than 158 papers on the subject have appeared; and with the exception of five or six containing certain criticisms on his labors, 'all the remainder confirm, in the strongest terms, by many hundreds of detailed observations, the value of these remedies.' A scruple of the salt dissolved in a wine-glassful of water flavored with tincture of orange-peel, is the average dose, and it should be taken every four hours; and in some cases, as in typhoid, a grain of quinine may be advantageously added to each dose. Dr. Polli's directions for its use in the prevention and cure of cattle-plague are given in the *British and Foreign Medico-Chirurgical Review*, Jan. 1872, p. 266. In the hands of other physicians, however, sulphurous acid has not led to such remarkable results as those of Dr. Dewar; and although recognized as a valuable remedy in many diseases, especially those caused by parasites, it cannot be said to have shown the same extraordinary efficacy as he claimed for it.

In consequence of the powerful antiseptic properties of sulphurous acid, either in the form of gas or gaseous solution in water, and of the sulphites, these substances have been employed for the purpose of preserving meat from putrefaction. A joint of meat or a fowl submitted to a daily sulphur fumigation may be kept fit for use for many weeks. The bisulphite of lime has been found to be the most applicable of the various compounds of this class as a preservative; and Messrs. Medlock and Bailey have patented a method of preserving meat by means of a preparation of this salt. In hot weather, a few drops of a strong solution of this salt will serve to keep fresh a pint of soup, jelly, milk, &c. Dr. Dewar patented a method of preserving meats by sulphurous acid, or some of its compounds; but as yet the process has not come into extensive use.

SU'LTAN, or SULTAUN, an Arabic word, signifying 'mighty man,' and evidently closely connected with the Hebrew word *shalal*, to rule, is in the East an ordinary title of Mohammedan princes, and also used in private life as a title of courtesy for people of high rank. It is given, *par excellence*, to the ruler of Turkey, who assumes the title Sultan-es-Selatin, or Sultan of Sultans. It is also applied to his mother and daughters; the word in Turkish having no grammatical gender, and corresponding also to our princess. The wife of the S. is not now entitled to the epithet S. or Sultana.

SULU ISLANDS, an archipelago of above 60 islands in the Mindoro Sea, between the Philippines and Borneo (q. v.). Ca. gayan Sulu, the chief of the islands, 36 miles long and 12 broad, contains the town of Soong, the residence of the sultan of the group. See PHILIPPINE ISLANDS.

SU'MACH (*Rhus*), a genus of small trees and shrubs, of the natural order *Anacardiaceæ;* having small inconspicuous flowers in panicles or in corymbs; a 5-parted calyx, 5 petals, springing from beneath a large orbicular disk; 5 stamens; a 1-celled germen with three stigmas; the fruit a small, nearly dry drupe, with bony *putamen*. The species are numerous, diffused over almost all parts of the world, except its coldest regions and Australia; and some of them, on account of peculiar principles which they contain, are of importance in the arts and in medicine; some are remarkable for their poisonous properties.—VENETIAN S. (*R. cotinus*), known also as Wig S. or Wig Tree, is a native of the south of Europe and west of Asia, and is often planted in Britain as an ornamental shrub. It has simple leaves, and hairy corymbs of fruit, which have a sort of resemblance to periwigs. The wood dyes yellow; and, with the addition of other substances, green and brown, and is known in trade by the name of *Young Fustic*. It is largely imported into Britain. The bark is sometimes used as a substitute for Peruvian Bark. The leaves are astringent, and are used in dyeing Turkey Red. The root is also used in dyeing, and the whole plant is used in Italy for tanning, and is there called *Scotino*. The seed resembles the almond in flavor.

The very acid fruit of the ELM-LEAVED S. (*R. coriaria*)—a native of the countries around the Mediterranean, with pinnate leaves, not unfrequent in British shrubberies—has been used from the earliest times, as it still is by the Turks and Persians, as a condiment with different kinds of food. Both the seeds and the leaves are used medicinally, in the south of Europe and the East, as tonic and cooling. This species is also extensively used for tanning, particularly in Turkey and in Spain. The leaves and twigs are used for dyeing black, the roots and fruit for dyeing red, and the bark for dyeing yellow.—Similar to this in its properties and uses is the VIRGINIAN S., or STAG'S-HORN S. (*R.*

typhina), a native of almost all parts of North America, and common in British shrubberies, which has the branches curiously crooked, and covered, when young, with a soft velvety down. It has pinnate leaves, with numerous leaflets.—The SMOOTH-LEAVED S. (*R. glabra*), a very similar species, also North American, has very acid leaves, which are eaten by children, and are

Sumach (*Rhus cotinus*), showing leaves, flowers, and fruit.

used in domestic economy and in medicine on account of the malic acid which they contain. The bloom of the fruit is also very acid. This species is sometimes troublesome in North America, overrunning ground as a weed.

Of the acrid and poisonous species, the most important is the POISON OAK (*R. toxicodendron*) of North America, a shrub from one to three feet high, with leaves of three leaflets, and a milky juice, which becomes black on exposure to air. The leaves are used in medicine in cases of paralysis, amaurosis, and other nervous affections, as a stimulant of the nervous system, also in chronic rheumatism and obstinate eruptions; but are efficacious only when fresh, as the poisonous substance is volatile. Similar to this in properties are the POISON IVY, or POISON VINE (*R. radicans*), the POISON ALDER, POISON S., or SWAMP S. (*R. venenata*), also known as Dogwood, and other North American species, the juice of which is very acrid, and even the emanations are injurious to some persons, who, from remaining a short time near these plants, or from handling them, experience swelling of the whole body, with subsequent inflammation of the skin, pustules, and violent itching, whilst it is remarkable that others appear quite unsusceptible of their influence.—The VARNISH S., or JAPAN VARNISH TREE (*R. vernicifera*), a native of Japan and Nepaul, yields a varnish much used in Japan for lacquer-work. This varnish is the juice which flows from wounds in the tree, and which becomes thick and black by exposure to the air, but is still so transparent that the finest veins of wood varnished with it may be seen through it. It is sometimes mixed with coloring matters, sometimes with gold-leaf finely ground. The expressed oil of the seeds becomes as hard as tallow, and is used for candles.

The name TANNERS' S. is given to *Coriaria myrtifolia*, a shrub of the south of Europe, of the natural order *Ochnaceæ*. The leaves are astringent, and are used for tanning, and for dying black.

SUMA'TRA (called by the Arabians *Srimat*, or *Srimata* 'the happy,' whence its present name), the most westerly of the Sunda Islands, lies south of the Malay Peninsula, from which it is separated by the Strait of Malacca. Lat. between 5° 45′ N. and 5° 50′ S. It is 1040 miles long and 266 miles in extreme breadth; area, 168,000 sq. m; pop., including that of the adjacent isles, 5,000,000, about two-thirds of whom are directly or indirectly under Netherlands rule. The Europeans in 1873 numbered 2654, not including the army in Atcheen.

Physical Features.—The Barisan Mountains run throughout its entire length, varying in altitude from 1550 feet in the south-west to 6000 under the equator. Lofty cones, of which about 20 are volcanoes, attain to from 6000 to upwards of 10,000 feet. Another series of mountains runs parallel with the Barisan, lofty plateaux of great extent linking them together at various points. On the west coast, a few miles of low land lie between the mountains and the sea, in some parts spurs reaching the shore in beetling cliffs. Wide alluvial plains, covered with dense jungle and forest, through which the rivers run sluggishly, forming deltas at their mouths, stretch along the north-east coast; while the tidal action is eating into the west coast, new ground is forming on the east.

Extensive valleys lie between the mountain chains. Several beautiful lakes are scattered over the interior. The largest is Lake Singkarah or Samawang, in Upper Padang, 17 miles long and 6 broad. It is 1167 feet above the sea, and discharges its waters by the Ombilin, which, flowing towards the east coast, becomes the Indragiri.

The mountain systems are of trachyte, granite, limestone, red sandstone, and a wide-spread conglomerate composed of granitic and quartzose particles, the hollows in many places being filled with lava. Sienite, porphyry, serpentine, jasper, basalt, and tufa occur. Tertiary deposits are found in the valleys, and in some parts of the coasts a rich vegetable mould rests on beds of red and grey clay, or on coralline limestone. Potter's clays are met with, and gold is widely diffused. Coal, iron-ore, copper, sulphur, lead, silver, saltpeter, alum, naphtha, &c., abound.

Rivers.—S. has many rivers, the most important being the Tūlang-Bawang; the Mūsi, or river of Palembang; the Djambi, Indragiri, and Siak, on the east; the Singkel, Tabūjong, Indrapūra, Moko-Moko, Bencoolen, and Padang Gūtjie on the west. The capes and bays are numerous, the Bay of Tapanūli being capable of containing a large fleet. A chain of islands lies parallel to S. in the Indian Sea. The most important are—Babi or Si Malu, Nias (q. v.), the Batū Islands, North Pora, Coco Island, South Pora, North Pagei, and South Pagei. To the south-east lies Banca, rich in tin, producing also iron, lead, silver, copper, arsenic, and amber.

Climate.—The climate of S. is moderately healthy, especially on the east coast. In Tapanūli, however, are large marshes, inducing intermittent and typhoidal fevers, dysentery, and other diseases. A slight increase of temperature takes place from October to March, the minimum being in May. Except in the highlands of the interior, where it is cool, the thermometer ranges from 70° F., at sunrise, to 94° at 2 P.M. The monsoons are irregular, and rain falls during all the months, though the quantity in October and December is double that in February and June.

Flora.—S. has many fine species of timber trees—as the Djati (*Tectona grandis*), the Maris, a hard and heavy wood, ebony, iron-wood, &c. The magnificent *Dryobalanops camphora*, and other resin-producing trees, are abundant. Several species of fig, the *Urceola elastica*, from which caoutchouc is obtained, and the gutta-percha tree (*Isonandra gutta*), are numerous. In the villages, the Bombax, or silk-cotton tree, forms a shady resting-place at noon. The lovely *Cinnamomum cassia*, the *Melaleuca leucadendron*, which yields the medicinal cajeput oil, the satin-wood (*Chloroxylon swietenia*), the gigantic reed (*Calamus draco*), from the ripe fruit of which the dragon-blood gum exudes, and a great variety of palms, form part of the botanical wealth of the island. Flowering plants and shrubs are numerous, and countless parasites garland the forest trees with flowers of every hue. The most curious of these is the *Rafflesia* (q. v.), which, clinging to the bark of large trees, spreads out the largest known flower, with a calyx 3 feet in diameter and 9 inches deep, and capable of containing 2 gallons of fluid.

The fruits are richer in flavor than those of Java. Among these are the guava, citron, oranges, lemon, durian, mango, bread-fruit, cocoa-nut, pomegranate, water-melons, pine-apples, and the highly-prized mangosteen, or berry of *Garcinia mangostana*. Cacao, cotton, maize, indigo, tobacco, gambier, and more especially rice, millet, pepper, and coffee, are cultivated.

Fauna.—The elephant, single and double horned rhinoceros, tiger, leopard, black bear and tiger-cat, wild swine, tapirs, antelopes, deer, monkeys (including the ourang-outang), ant-eaters, many kinds of bat, &c., abound. Buffaloes, cows, goats, horses, sheep, and swine are kept by the natives. The peacock and the pheasants of S. are of rare beauty. Hippopotami and crocodiles frequent the rivers, which have many kinds of fish, including a species of salmon.

Geographical and Political Divisions.—The kingdom of Atcheen (q. v.), Acheen, or *Achin* occupies the north-western portion of the island (extending further south on the east coast than on the west); area, 20,000 sq. miles; pop. about 400,000. The Dutch began in 1873 a tedious was for the subjugation of the country, which in 1882 war not yet completed. It is well cultivated, and produces much pepper. Singkel, Tapanūli, and Lower Padang, administratively under the Presidency of Padang, lie in succession to the south-east of Acheen. Bencoolen stretches along the west coast from 101° to 104° 40′ E. long.; and the extreme south and the east coast, between 4° 4′—5° 56′ S. lat., form the Lampong districts. North of these is the residency of Palembang, with the kingdom of Djambi, ruled over by a native prince under Dutch control. Farther north are Indragiri, Kampar, and Siak, governed as Djambi. Between Siak and Acheen are many petty states.

People.—The natives are chiefly Malays who profess Mohammedanism. In appearance, manners, and customs, however, the inhabitants of Acheen and the Lampongs differ widely from those of other parts. The Acheenese are tall, well-made, active, and intelligent, but cunning, proud, treacherous, and blood-thirsty. They live simply, but are slaves to opium. The Lampongers are of middle stature, well formed, of pleasant exterior, mild, but uncivilized and lazy. Caste prevails, and they follow the usages

of their fathers, Mohammedanism being imperfectly known and practised. Polygamy obtains, the wives being bought from their relatives. The houses are on posts of iron-wood, several families living under the same roof. In other parts of S. the usual Malay type is found. The Kūbūs, in the north-west of Palembang, are probably the remains of the aborigines, a harmless race who live chiefly by the chase and fishing. Theft and murder are scarcely known among them. They believe in an after spirit-life.

Trade and Produce.—The imports and exports of the independent and half-independent kingdoms cannot be ascertained. Acheen alone produces 8000 tons of pepper annually, and also exports gold, precious stones, cotton, raw silk, sapan wood, benzoin, camphor, sulphur, betel, &c., to the west of India by way of Pūlū Penang and Singapore, receiving in return manufactured goods, salt, opium, &c. On the S.W. coast, Bencoolen, the Lampongs, and Palembang, the imports have an annual value of about £750,000; the exports to £850,000. Java has nearly half the trade, Europe and Eastern countries the remainder. Imports—rice, cotton and other textile fabrics, &c.; exports—benzoin, gum, elastic, resin, pepper, rattans, cotton, coffee, drugs, ivory, dyestuffs, edible nests, wax, tobacco, bêche-de-mer, &c. The rice-culture is extensive, the west coast producing as much as 320,000 tons in a single year. The coffee yield varies from 5500 tons to nearly twice as much. Upper Padang sends the largest quantity of coffee and rice, with much cocoa-nut oil, to market.

History.—Marco Polo visited S. in the 13th c,, Alvaro Talezo in 1506, and Siquera in 1509, the Portuguese then entering into trading relations with the natives. About 90 years later, the Dutch under Houtman reached the island, and on a second visit he was treacherously murdered at Acheen. In 1601, two ships from Zeeland, with the Netherlands commissioners, General De Roi and Laurens Bikker, arrived, were favorably received by the king, obtained a full cargo, and returned with two Acheneese ambassadors. Later, the Dutch drove the Portuguese from their factory at Pūlū Tjinko, to the south of Padang; and in 1666, the latter place became the seat of the Netherlands power on the west coast. In 1795 Padang was taken by the British, and retained till 1819. A few years after, Bencoolen was also given up to the Dutch, and the southern division of the island soon fell under the same rule. Various rebellions against the Netherlands dominion have since arisen, with the uniform result of extending the power of the Dutch towards the interior and the north. The appalling eruption of 1883 at the volcanic island of Krakatoa, between S. and Java, raised a vast sea-wave which swept destructively the southern shore of S., and raised a new line of volcanic cones in the Straits of Sunda.—See the work, *Nederlandsch Indie*, by Nijhoff; *The Malay Archipelago*, by A. R. Wallace (1869); *Australasia*, by A. R. Wallace (1880).

SUMBA'WA, one of the chain of islands to the east of Java, lies between 8° 4′—9° 2′ S. lat., and 116° 50′—119° 15′ E. long., is now divided into the kingdoms of Sumbawa, Bima, Dompo, and Sangar, each governed by its own sovereign. Area, 5838 square miles. Pop. nearly 100,000. The island is mountainous, but except the volcano Tambora, which is 9522 feet, the elevation does not exceed 5660. The most valuable timber-tree is the Djati (*Tectona grandis*, or Indian teak), and the tamarind is so abundant as to be little valued. Rice is extensively grown. Sapan-wood is contracted for with the princes, by the Netherlands colonial government.

The natives of S. belong to the Malay race, but speak three different languages. They are inoffensive and industrious, murder, robbery, and theft being almost unknown. Many of them are Mohammedan, but the mountaineers are chiefly heathen, with an idea of a supreme being. Ancient relics recently found in Bima, indicate that they were formerly professors of Hinduism.

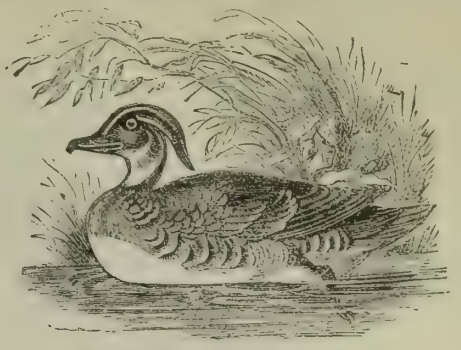
In 1815, an eruption of Tambora depopulated the kingdoms of Tambora and Papekat, 12,000 lives being lost, and great damage done to the whole island by the ashes. Another took place in 1836, and one of Gunong Api, in Bima, in 1860, but with little loss.

SU'MBUL (see MUSK PLANT) has been extensively employed for some years past, both in this country and in America, in the treatment of epilepsy, hysteria, and other diseases of the nervous system. It has a musk-like odor, and an aromatic and somewhat bitter taste. It may be given in the form of infusion, tincture, or resin.

SU'MMARY DILIGENCE, in the practice of the law of Scotland, means issuing execution without the formality of an action, as a creditor enforcing payment of a bill of exchange or of a bond.

SUMMER, a horizontal beam, called also Breast Summer.

SUMMER DUCK, or WOOD DUCK (*Dendronessa sponsa*, or *Aix sponsa*), a very beautiful species of duck, of the section having the hind-toe destitute of membrane, a native of North America. It is found during the breeding season in almost all parts of the United States, and as far north as Nova Scotia, migrating southwards in winter, when it abounds in Texas and Mexico, but some remain during winter even in Massachusetts. It has been found capable of domestication.—Very similar to it is the MANDARIN DUCK (*Dendronessa* or *Aiz galericulata*), a Chinese species. Both of these species have the power of perching on trees. The S. D. makes its nest in the hollow of a tree.



Summer Duck (*Dendronessa sponsa*).

SUMMER ISLANDS, a small archipelago of islets off the west coast of Scotland, near the entrance of Loch Broom, an inlet in the north-west of the county of Ross. The islets are about 20 in number; and the largest of them, Tanera, 2 miles long, and 1 mile broad, has a pop. (1881) of 119.

SU'MMONS, in English Law means generally a writ directed to a party to appear and answer some complaint before a court or judge. It is the first writ in an action at law; and a similar writ issues incidentally both in Chancery and in interlocutory matters. It is also the first step in proceedings before justices.—In Scotland, it is also the first writ in an action.

SUMNER, CHARLES, American statesman, was born at Boston, Massachusetts, January 6, 1811. His father was a lawyer, and for many years sheriff of the county. He was educated at Harvard College, where he graduated in 1830; studied law at the Cambridge Law School; was admitted to the bar in 1834, and entered upon a large practice; edited the *American Jurist;* published three volumes of Sumner's *Reports of the Circuit Court of the United States;* gave lectures at the Law School, but declined a proffered professorship; and from 1837 to 1840, visited England and the continent of Europe. On his return, he edited Vesey's *Reports*, in 20 vols., and in 1845, made his début in politics in a 4th of July oration, on the True Grandeur of Nations—an oration against war and the war with Mexico, pronounced by Mr. Cobden the noblest contribution by any modern writer to the cause of peace. Identifying himself with the Free-soil party, he was, in 1850, chosen U. S. senator from Massachusetts, in place of Daniel Webster, where he opposed the Fugitive Slave Law, and declared 'freedom national—slavery sectional.' In 1856, he made a two days' speech on 'the Crime against Kansas,' some of which was of a violently personal character, in consequence of which he was attacked in the Senate Chamber, May 22, and severely beaten by Preston C. Brooks, and so severely injured that his labors were suspended for three or four years; during which he visited Europe for repose and health. Returning to the Senate, he supported the election of Mr. Lincoln, urged upon him the proclamation of emancipation, and became the leader of the Senate, as chairman of the Committee on Foreign Relations. In 1862 he was again elected a senator, and re-elected in 1869. In 1871 he opposed the annexation of Hayti to the United States. He published *White Slavery in the Barbary States* (1853); *Orations and Speeches* (1850), &c. He died in 1874. A *Memoir and Letters* appeared in 1878.

SU'MPTUARY LAWS (Lat. *sumtus*, expense), laws passed to prevent extravagance in banquets, dress, and private expenditure. They abound in ancient legislation. The Locrian legislator, Zaleucus, 450 B.C., ordained that no woman should appear in the streets attended by more than one maid-servant, unless she were drunk, or wear gold or embroidered apparel, unless she designed to act unchastely. At an early period in Roman history, the Censors, to whom was intrusted the superintendence of public and private morality, punished with the *notatio censoria* all persons guilty of luxurious living; but as the love of luxury grew with the increase of wealth and foreign conquest, various legislave enactments were passed with the object of restraining it. The Lex Orchia, 161 B.C., limited the number of guests to be present at a feast; the Lex Fannia, 161 B.C., regulated the cost of entertainments, enacting that the utmost sum which should be expended on certain festivals was to be 100 asses, 30 asses on certain other festivals, and 10 asses on an ordinary entertainment, where also

no other fowl than one hen was permitted to be served up, and that not fattened for the purpose. There were also the Lex Didia, Lucretia, Cornelia, Æmilia, Antia, Julia, and others, most of them passed in consequence of the practical disregard of the similar laws that had preceded them; but they all seem to have been habitually transgressed in the later times of the Republic.

Sumptuary laws were in great favor in the legislation of England from the time of Edward III. down to the Reformation. Statute 10 Edward III. c. 3, narrates, that 'through the excessive and over-many costly meats which the people of this realm have used more than elsewhere, many mischiefs have happened; for the great men by these excesses have been sore grieved, and the lesser people, who only endeavor to imitate the great ones in such sorts of meat, are much impoverished, whereby they are not able to aid themselves, nor their liege lord, in time of need, as they ought, and many other evils have happened as well to their souls as their bodies;' and enacts that no man, of whatever condition or estate, shall be allowed more than two courses at dinner or supper, or more than two kinds of food in each course, except on the principal festivals of the year, when three courses at the utmost are to be allowed. All who did not enjoy a free estate of £100 per annum were prohibited from wearing furs, skins, or silk, and the use of foreign cloth was allowed to the royal family alone. Act 37 Edward III. declares that the outrageous and excessive apparel of divers people against their estate and degree is the destruction and impoverishment of the land, and prescribes the apparel of the various classes into which it distributes the people; it goes no higher than knights, but there are minute regulations for the clothing of women and children. This statute, however, was repealed the next year. In France, there were sumptuary laws as old as Charlemagne, prohibiting or taxing the use of furs; but the first extensive attempt to resist extravagance in dress was under Philip IV.

By an edict of Charles VI., no one was allowed to exceed a soup and two dishes at dinner. Sumptuary laws continued to be introduced in England in the 16th, and in France as late as the 17th century. Scotland had also a similar class of statutes. The Scottish Parliament attempted to regulate the dress of the ladies, to save the purses of the 'puir gentlemen their husbands and fathers.' There was a prohibition against their coming to kirk or market with the face muffled in a veil; and statutes were passed against superfluous banqueting, and the inordinate use of foreign spices 'brocht from the pairts beyond sea, and sauld at dear prices to monie folk that are very unabill to sustain that coaste.' Neither in England, Scotland, nor France do these laws appear to have been practically observed to any great extent: in fact, the kings of France and England contributed far more, by their love of pageantry, to excite a taste for luxury among their subjects, than by their ordinances to repress it. Mr. Froude suggests that such statutes may have been regarded, at the time when they were issued, rather as authoritative declarations of what wise and good men considered right, than as laws to which obedience could be enforced. Enactments of this kind have long been considered to be opposed to the principles of political economy. Most of the English sumptuary laws were repealed by 1 James I. c. 25, but a few remained on the statute-book as late as 1856.

SU'MTER, Fort (originally spelled *Sumpter*, after General Sumpter, in whose honor it was named), an American fort of the second class, built 1845—1855, in the form of a truncated pentagon 50 feet high, on an artificial island, at the entrance of Charleston Harbor, two and a half miles distant from Forts Moultrie and Pinckney, on either side. On the secession of South Carolina, December 1860, Major Anderson, in command of the defences of the harbor, was called upon to surrender them to the state authorities. Instead of doing this, he abandoned the other forts, and occupied Fort S., mounting 52 guns, with a garrison of 70 men and 30 or 40 workmen. This was considered an act of war by the Confederates and their troops, who, under command of General Beauregard, took possession of Forts Pinckney and Moultrie, and erected additional batteries. While the surrender of the fort was under consideration, a fleet was sent from New York for its relief. On its appearance off the harbor, the attack on the fort was opened by General Beauregard, April 12, 1861, and it surrendered on the 13th. This event aroused the North, and began the war which terminated in 1865. During the siege of Charleston, this fort was battered by the heaviest artillery, until its walls were completely crushed and shattered. The flag-shaft was shot away fifty times, and thousands of tons of iron projectiles were mingled with the débris of the fort; but the garrison constructed a still stronger fortress on its ruins, and held it for three years against assault and bombardment, until the operations of General Sherman compelled its evacuation, and the United States flag was again raised April 14, 1865; an event soon followed by the evacuation of Richmond, and the surrender of all the Confederate armies.

SU'MY, a town of Russia, in the government of Kharkov, and 90 miles north-west of the town of that name, on the Psiol. It contains several factories, and has an important annual fair. Pop. (1880) 26,000.

SUN, The, the great luminary upon which not only our well-being but our very existence depends, has been from the earliest ages a source of wonder and admiration, and its worship was probably the very first form of idolatry. See Sun-worship.

When the true system of the universe became known, one of the first labors of astronomers was to ascertain the distance and size of the sun, and these have been known for some time with tolerable precision; but until lately, the most vague and unsatisfactory theories regarding its chemical and physical constitution have continued to prevail.

Within the last few years, however, our knowledge of its chemical and physical constitution has increased with a rapidity probably unequalled in any other branch of science.

Our knowledge regarding the sun is best arranged under three heads; viz., *The general relations of the sun to our globe; the sun's chemical constitution;* and *its physical constitution.*

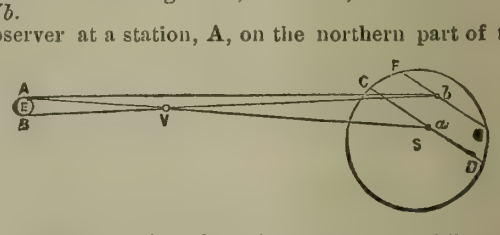
Relations of the Sun to the Earth, as the Source of Light and Heat.—In order to appreciate the grandeur of the scale on which solar activity is carried on, it is only necessary to know a few facts relative to the sun, which are best expressed by numbers.

1. *Distance of the Sun from the Earth.*—The difficulty in ascertaining the Parallax (q. v.) of the sun arises from the smallness of the base line as compared with the distance of the object. The distance of the observing stations must always be less than 8000 miles; from this the parallax of the moon, which is only 30 times 8000, can be observed directly with tolerable nearness. But when the distance is many thousand times the length of the base line, the triangle is 'ill-conditioned' or unfavorable to accuracy, and the problem must be approached indirectly. The first attempt to measure the distance of the sun was that made by the Greek astronomer Aristarchus in the third century B.C., who made it only about one-twentieth of what we now know it to be. Even the great astronomer Kepler in the seventeeth century could only say that the distance must be at least between 13 and 14 millions of miles. Subsequent estimates—for, owing to the imperfection of the methods and instruments, they were little better than estimates—rose to 80 millions. At last, in 1716, the English astronomer Halley proposed a method of employing the transits of Venus. Accordingly the transits of 1761, 1769, were observed in a variety of places; but the results at first deduced were discordant and unsatisfactory, until in 1824 the German astronomer Encke 'discussed' the observations of 1769, and arrived at a distance of about $95\frac{3}{10}$ millions of miles; and this number held its place in books of astronomy for a good many years. In the meantime, in the absence of transits, other methods, become possible through the growing perfection of astronomical instruments, were tried, and most of them concurred in pointing to a value nearly $3\frac{1}{2}$ millions less than that above stated; so that 91,500,000 came to be accepted as the approximate distance of the sun, until the transit of 1874 should settle it more definitely.

A transit can occur only when the planet is in or near one of her nodes at the time of inferior conjunction, so as to be in a line between the earth and the sun. The coincidence of these two conditions follows a rather complex law. There are usually two transits within eight years of one another, and then a lapse of 105 or 122 years, when another couple of transits occur, with eight years between them. The transit of 1874 had for its successor that of 1882, and there will not be another until June 2004.

The way in which a transit is turned to account may be understood by the help of the accompanying diagram, where E represents the earth; V, Venus; and S the sun. It is to be premised that the *relative* distances of the planets from the sun are well known. Their periodic times can be observed with accuracy, and from these by Kepler's (q. v.) Law we can deduce the *proportions* of the distances, but not the distances themselves. It is thus known that if the distance of the earth from the sun is taken as 100, that of Venus is 72. In the fig. then, AV is 28, or about one-third of V*a* or V*b*.

An observer at a station, A, on the northern part of the earth



will see the planet projected on the sun as at *a*, while a southern observer will see it at *b*. The distance of the sun from Venus being about three times her distance from the earth, it is obvious that the distance *ab* will be three times the distance AB; and it is a great advantage to have the stations A, B, as far apart as possible, as the interval *ab* is thus increased and its measurement rendered more accurate.

But how is it measured? For each observer sees only one of the spots, and does not know where the other is; and there are no permanent marks on the sun's surface to guide us. The difficulty is got over in the following way: Each observer notes the exact duration of the transit, that is, the time the spot takes to travel from C to D, or from F to G. Now as we know the rate of Venus's motion in her orbit, this gives us the lengths of the lines CD and FG in minutes and seconds of arc. Knowing then the angular diameter of the sun (32′) and the lengths of two chords CD and FG, we can easily, by the properties of the circle, find the distance *ab* between them. This gives us the angle *a*A*b*. In the triangle AV*b*, then, we know the angle at A and the proportion of the sides AV and V*b*, and from that we can find the angle A*b*V or A*b*B. Now this is the quantity sought, being the parallax of the sun as seen from two stations on the earth. Whatever the distance AB actually is, the angle is reduced to correspond to a distance equal to the earth's semi-diameter. The parallax deduced by Encke, as above referred to, was only 8″·5776, while the parallax corresponding to the other smaller measurement above stated is 8″·94. The advantage of this roundabout procedure is that a comparatively large angle (*a*A*b*) is measured in order to deduce from it a smaller (A*b*B), so that any error in the measurement is diminished in the result.

The transit of 1874 was observed at more than fifty stations, astronomers from all the civilized world taking part in the work. The labor of discussing and comparing the observations has not yet been overtaken, but several partial results have been announced, which still show considerable discrepancy. The chief source of uncertainty arises from the difficulty the observers found in determining the exact moment of 'ingress' and 'egress' of the planet, owing to the dense atmosphere of the latter rendering the limbs of the two bodies indistinct and distorted. Much was expected from the multitude of photographic pictures taken, but they have proved a failure. They are said to lack the necessary sharpness, and to be liable to other sources of error. The first partial discussion of the British observations gave, according to the Astronomer Royal, a result of $93\frac{4}{10}$ millions of miles. A more extended discussion since announced results in $92\frac{5}{10}$ millions of miles.

Elaborate arrangements were made, on an international plan, for observing the transit of 1882, and attempts made to obviate the defects of previous observations. In the meantime astronomers are turning with greater hope to other methods, especially to observations of Mars, and of some of the minor planets. From observations of Mars made in 1862, the American astronomer Newcomb deduced a distance of $92\frac{8}{10}$ millions of miles. The velocity of light, which has been determined by the ingenious optical experiments of Foucault and others, has also been pressed into the service of the problem. The aberration of Light (q. v.) results from the relation of the velocity of light to that of the earth's motion in her orbit; and from the observed amount of the aberration we are thus able to deduce the earth's velocity. From knowing then the time of the earth's revolution, we can find the circumference of her orbit, and hence her distance from the sun. The most careful investigation by this method gives a distance of 93 millions of miles. An ingenious method of observing the parallax of Mars at its opposition, first suggested by the Astronomer Royal, but carried out by Mr. Gill on the island of Ascension in 1877, promises still more satisfactory results. The essence of the method consists in this, that instead of depending upon two sets of observers at different parts of the earth, one observer and one station are made to suffice. One observation is taken in the evening when the planet is rising, and another in the early morning when it is setting. In the meantime the rotation of the earth has transported the observer 6000 or 7000 miles through space, and this forms his base line. Mr. Gill's observations were made by means of the heliometer, the most effective of instruments for such purposes. From such of his observations as had been reduced at the end of 1878, Mr. Gill announces his belief that the sun's distance will prove to be nearer to 93 than to 92 millions of miles.

The other important numerical facts relative to the sun are the following: Its *diameter* calculated on the basis of the shorter distance hitherto received, is, in round numbers, 850,000 miles, or more than 107 times the mean diameter of the earth; so that the *volume* or bulk of the sun exceeds that of the earth 1,200,000 times, and is 600 times greater than the bulk of all planets at present known, together. The *mass* of the sun, or quantity of matter it contains as measured by weight, exceeds that of the earth only 300,000 times; and thus it appears that the matter of the sun has only one-fourth the density of that of the earth. From this and other facts, it is inferred that the matter of the sun exists for the most part in a gaseous condition. Still his mass is 740 times greater than the masses of all known planets put together. The *period of rotation* of the sun upon its axis, which Galileo was the first to calculate from observations of the sun-spots, and which takes place in the same direction as that of the earth, is about 25 days 8 hours. It appears, however, that this period varies according to the solar latitude of the spots from which it is calculated. The *inclination* of the axis of the sun to the ecliptic is about 7½°, and the *longitude of the ascending node* is about 74° 30′.

2. The form or *figure of the sun* has been the subject of recent investigations. The polar and equatorial diameters of the sun's disc as observed, have been supposed to differ, though by a very small quantity only. The photographs of the sun do not quite agree in the amount of the value for the diameter with that given by observations.

The general laws by which the relation of our earth to the sun, as the source of light and heat, is governed, are of the most simple kind. The rays which emanate from the sun's disc into space, proceed in diverging lines, and on arriving at the earth, their intensity will be inversely proportional to the square of the sun's distance. This may be called the primary law; but the more obvious phenomena of solar heat and light are manifested to us under a secondary law depending on the obliquity of incidence of the sun's rays. See CLIMATE, EARTH, TEMPERATURE, &c.

3. *Chemical Constitution of the Sun.*—Astronomy has weighed and measured the sun long ago, and in our days, chemistry, aided by physics, makes an analysis of it. The way in which this surprising result is arrived at is explained under SPECTRUM. The main fact on which the method rests is briefly this: that a substance, when comparatively cold, absorbs the very same rays which it gives out when heated. Hence it was inferred by Kirchhoff, that if there were sodium or iron in a comparatively cold state in the solar atmosphere, above the source of light, these substances would produce black lines corresponding in spectral position with the bright lines which they give out when heated. On this principle the presence in the solar spectrum of hydrogen, magnesium, calcium, sodium, and metals of the iron group has been ascertained with something like certainty. There are less clear indications of other metals such as zinc and lead; while metals of the tungsten, antimony, silver, and gold classes have been searched for in vain. Of the metalloids, such as oxygen, carbon, nitrogen, sulphur, and the like, none had been detected till, in 1877, Professor Henry Draper of America announced the discovery of oxygen. The presence of these substances in the sun is hardly doubted, but their identification is difficult. A chief source of complication in research of this kind is the effect on the spectra of substances produced by differences of temperature and pressure. Excessive heat seems to dissociate the groups of atoms forming the molecules into simpler groups, and thus produces a different spectrum difficult to recognize. The labors of Lockyer, Huggins, Janssen, Draper, and others are directed towards overcoming these and other obstacles.

4. *Physical Constitution of the Sun.*—Since the first discovery by Galileo of those remarkable phenomena on the sun called *sun-spots*—dark patches with an area frequently exceeding several times the surface of the earth—an immense variety of theories, as to the probable constitution of the solar body, has been brought forward by nearly every observer. Solar photography promises valuable aid in this research by enabling us to keep a permanent record of passing phenomena, ready at any time for deliberate measurement and comparison.

One of the most important discoveries in connection with sun-spots, science owes to Dr. Alexander Wilson of Glasgow, who, in the year 1769, observed certain general and remarkable features of sun-spots, which enabled him to establish the significance of these phenomena for a solution of the question as to the sun's physical constitution. These features are as follows: When a spot was near the middle of the sun, it was found to consist of a dark *central* part, called the *nucleus* or *umbra*, and *around this* was a comparatively brighter envelope, called the *penumbra*, and at such a time both parts were distinctly visible. But as the spot approached one border, the penumbra on the side nearest the observer became gradually more and more foreshortened, while the penumbra on the other side grew broader and broader, and at length, as the spot was disappearing, that is, passing the edge of the limb, the near side of the penumbra, as well as the dark central part, entirely vanished, nothing remaining except the opposite penumbra. When a spot made its appearance on the other side of the border, Wilson noticed the same phenomena in an opposite order, and soon discovered that they were nearly universal. It followed from these observations at once, that every spot presents the appearance of a funnel-shaped opening in the sun's body, which by the rotation of the latter, successively presented the described appearances. These observations have been abundantly confirmed by the photographic records of Messrs. De la Rue, Stewart, and Loewy.

Schwabe showed, as the result of nearly forty years' observations, that the number of groups of sun-spots is not the same from year to year, but has a maximum about every ten or eleven years; and General Sabine recorded the wonderful fact, that the various epochs of maximum spot-frequency are also those of

maximum disturbance of our earth's magnetism. Here, then, we have a very curious bond of union between the sun and the planets of our system

It was next shown by Carrington that sun-spots have a proper motion of their own—those near the solar equator moving faster than those near the poles.

While spots are darker than the general surface of the sun, there are also frequently observed patches brighter than the general surface. These are called *faculæ*, and they generally accompany spots, most frequently in their wake; but they are only distinctly visible near the sun's limb, and lose their specific luminosity near the center of the sun's disc.

Another phenomenon connected with our luminary is not less remarkable than sun-spots. This is the red flames, or *protuberances*, which were first observed surrounding the sun's disc on the occasion of a total eclipse, but which by ingenious methods of observation can now be rendered visible even when the sun is not eclipsed. This colored envelope, less brilliant than the *photosphere*, or light-giving surface, and having a mean height of 5000 to 6000 miles, is known as the *chromosphere*, and seems to consist mainly of incandescent hydrogen, jets of which are seen at times to be projected to a height of 200,000 miles. The velocity of these movements has been calculated to exceed at times 120 miles a second. Above the chromosphere there is a far deeper layer of cooler, sub-incandescent gases, among which is an unknown substance, which chiefly composes the outer portion, and is apparently lighter than hydrogen. These gaseous envelopes, extending together to 300,000 or even 500,000 miles above the photosphere, are now believed to cause the appearance called the *corona*, or white halo, which is seen to surround the dark body of the moon during an eclipse of the sun.

If a spot be a hollow, as we have reason to suppose, it is only necessary to believe that there has been a descending current of this cold absorbing atmosphere to account for the want of luminosity. In like manner, on this hypothesis, a facula will be a portion of the luminous matter, which has been removed high up into the atmosphere, and which thus escapes the absorbing influence of the atmosphere. A spot may thus be supposed to be produced by two currents—one ascending, and carrying the hot luminous matter up; the other descending, and carrying the cold atmosphere down. The photosphere is thus in a constant state of agitation like ebullition.

Spots and their accompanying faculæ are an indication of the activity of those 'convection currents' by which heat is brought to the surface to replace what has been radiated off. Their temporary prevalence then is held to be a sign of more than ordinary solar activity or expenditure of energy. This is palpably manifested on our globe in the greater magnetic disturbance that takes place when sun-spots are numerous, as before mentioned. The diurnal range of the magnet freely suspended in the Kew Observatory, shows an unmistakable correspondence with the waxing and waning of the spotted area on the sun; and the frequency of auroræ is found to be in perfect correspondence with prevalence of spots. It is natural to seek to connect cycles of weather with the spot-period of the sun, but nothing has yet been conclusively established. A coincidence has seemingly been made out between the recurrence of famines in Southern India through deficient rain and the period of minimum spots; but the coincidence does not hold for other localities. Attempts have even been made to bring commercial crises and other recurring events into the spot-cycle.

As to the cause of the periodicity of sun-spots, observations made at Kew seem to establish a connection between the behavior of spots and the proximity of prominent planets; and it may thus be found that the recurrence of certain planetary positions in some way determines the spot-period.

SUN AND FIRE WORSHIP. All investigation tends to show that nature-worship was the basis of all polytheistic religions, and that the chief deities of the several mythologies were originally personifications of the sun, or of particular influences of the sun. The original solar nature of Jupiter, Zeus, Odin, Baal, Amen Ra (see EGYPT), Indra, &c., can hardly be mistaken. See those heads; also SCANDINAVIAN MYTHOLOGY, PHŒNICIA; and for a full development of the subject, Max Müller's essay on *Comparative Mythology* (Oxford Essays, 1856). The actual sun, however, still continued an object of worship, more especially as in the abstract and more strictly personal gods, moral and intellectual attributes came to predominate over and obscure the physical (see HELIOS); and with the worship of the sun was more or less closely associated that of fire—his representative on earth. See PARSEES, NEEDFIRE, BELTEIN.

The most complete system of sun-worship that we have any account of is that existing in Peru when discovered by the Spaniards (1526). 'Our northern natures can hardly comprehend how the sun, and the moon, and the stars were imaged in the heart of a Peruvian, and dwelt there; how the changes in these luminaries were combined with all his feelings and his fortunes; how the dawn was hope to him; how the fierce mid-day brightness was power to him; how the declining sun was death to him; and how the new morning was a resurrection to him: nay, more, how the sun, and the moon, and the stars were his personal friends, as well as his deities; how he held communion with them, and thought that they regarded every act and word; how, in his solitude, he fondly imagined that they sympathized with him; and how, with outstretched arms, he appealed to them against their own unkindness, or against the injustice of his fellow-man.'—Helps's *Spanish Conquest of America*. The Incas, as the Peruvian monarchs were called, claimed to be children of the sun, and his representatives on earth. Their government was a despotic theocracy, of which the Inca was both high-priest and king. In Cuzco, the capital, stood a splendid temple to the sun, all the implements of which were of gold. On the west end of the interior was a representation of the sun's disc and rays in solid gold, so placed that the rising sun, shining in at the open east end, fell full upon the image, and was reflected with dazzling splendor. In the place or square of the temple, a great annual festival was held at the summer solstice. The multitude, assembled from all parts of the empire, and presided over by the Inca, awaited in breathless solemnity the first rays of their deity to strike the golden image in the temple, when the whole prostrated themselves in adoration. Sacrifices, similar to those of the Jews, were offered on the occasion, and bread and wine were partaken of in a manner strikingly resembling the Christian communion.

'It must not be supposed that the sun alone absorbed the devotion of the Peruvians. There was little in nature that they did not contrive to make a deity of. The Moon, as the spouse of the Sun, the planet Venus as his page, the Pleiades, and the remarkable constellation of the Southern Cross, were minor deities. The rainbow and lightning were also worshiped as servants of the Sun; and fire, air, earth, and water were not without adoration.'

S'UNAH'S'EPHA is, in the ancient legends of India, the son of a poor Brahman, Ajîgarta, who was sold by his father for 100 cows to *Haris'chandra* (q. v.), and offered by the latter as a victim to Varun'a, instead of his own son Rohita, whom he had pledged himself to sacrifice to this god. The legend relates that when S. was bound to the sacrificial post by his own father—for no priest could be found to perform the ceremony—and when his father came whetting his sword to kill him—for neither was any priest to be found who would perform such a sacrifice—S. prayed in succession to the gods Prajâpati, Agni, Savitr'i, Varun'a, again to Agni, then to the Vis'we-Devâh', Indra, the As'wins, and the Dawn; and while he praised the Dawn with three verses, at the delivery of each verse his fetters became looser, and when the last verse was said, he became free again. He left afterwards the family of his parents, and was adopted by *Vis'wâmitra*, under the name of S'unah's'epha Devarâta (the God-given). The *Aitareya Brâhman'a* (see VEDA), where this legend is related, also ascribes to him the first performance of some Vedic ceremony.

SU'NART, LOCH, an inlet of the sea in the west of Argyleshire, length, 19 miles.

SUNBIRDS (*Cinnyridæ*), a family of birds of the order *Insessores*,

Sunbird (*Nectarinia phœnicura*).

and tribe *Tenuirostres*, which may be regarded as a connecting link between the Creepers and the Humming-birds, and as occupying nearly the same place in the tropical parts of the Old World which belongs to the humming-birds in America. They are all of small size, although none are so small as the smallest humming-birds; they rival humming-birds in brilliancy of plumage, and like them they feed on the juices of flowers, which they suck by

their long bill; they do not, however, flutter on the wing when feeding, like humming-birds, but perch on or beside the flower into which the bill is to be inserted. The species are very numerous, and are natives of the southern parts of Asia, the Eastern Archipelago, and Africa. The resplendent metallic plumage belongs only to the male, and only to the breeding season.

SU'NDA ISLANDS, that great chain of islands belonging to Malaysia, running east, commencing with Sumatra (q. v.), and ending with Timor (q. v.), and separating the Java Sea from the Indian Ocean. Sunda Strait is a passage from 79 to 90 miles in breadth, between Sumatra and Java. A dreadful volcanic eruption (26th August 1883) at the small island of Krakatoa, in the strait, did much damage on the shores both of Sumatra and Java, and raised new volcanic islets in the strait, so that a new survey was rendered necessary.

SU'NDAY. See SABBATH; LORD'S DAY; PUBLIC-HOUSES.

SUNDAY SCHOOLS were founded about the year 1780 or 1781 by Robert Raikes, a printer in Gloucester. Business leading him into the suburbs of the town, inhabited by the lowest class of the people, he was struck with concern at seeing a group of children, miserably ragged, at play. He was informed that 'on Sunday the street was filled with a multitude of wretches, who, having no employment on that day, spent their time in noise and riot, playing at chuck, and cursing and swearing.' To check this deplorable profanation of the Lord's Day, he engaged four women, who kept dame schools, to instruct as many children as he should send them on the Sunday, in reading and the church catechism, for which they were to receive one shilling each. In a short period, a visible improvement was effected both in the manners and morals of the children, who came in considerable numbers; they attended church with their mistresses, and a great many learned to read and say their catechism. Such was the origin of the Sunday schools. This excellent scheme was noticed in the Gloucester newspaper in 1783; but a letter of Mr. Raikes, from which the above account is taken, published in the *Gentleman's Magazine* in 1784, first drew general attention to it. Numerous schools, formed on the same model, sprang up in all the principal towns; and a society, under high patronage, was formed in London in 1785 for the establishment and support of Sunday schools throughout the kingdom, which in fourteen years expended £4000 in payment of teachers. Her Majesty, Queen Charlotte, admitted Mr. Raikes to an audience, and expressed her high approbation of his plan. This was the first stage of the Sunday school. The great impediment to its prosperity was the expense of hiring so many teachers. Even in Gloucester, the birthplace of the Sunday schools, after Mr. Raike's death in 1811, all the Sunday schools were closed for a time owing to want of funds.

Whoever first conceived the idea of gratuitous instruction, has nearly as great merit as Mr. Raikes himself; but probably it was suggested by necessity to many minds in different places at the same time. It was the means of starting Sunday schools on a new career of success, and the idea spread so rapidly, that, by the year 1800, the teaching was almost universally gratuitous. A higher class of teachers offered their services; the schools ceased to be filled by the very poorest alone; handsome buildings were erected in connection with the different churches and chapels, or by general subscription, and that system was organized which has covered the land with schools. The secular teaching, which in certain instances included writing and arithemetic, was not of a very high order; but it placed the key of knowledge in the hands of multitudes who would otherwise have been unable to read; and the religious instruction with which it was combined has moulded the character of some of the best men in England. In 1803, the Sunday School Union was formed, which, by its numerous publications, its traveling agents, and its connection with branch societies in every part of the kingdom, has exercised great influence on the Sunday school cause. The Institute of the Church of England, which operates in a similar manner, is of later date. Within the last twenty years, the Sunday school has entered upon a third stage of its history. The improvement and multiplication of week-day schools obviate the necessity for teaching reading in Sunday schools, so that they have gradually become restricted to religious instruction. This for a time threatened to affect their popularity, but as the teachers were earnest men, they cultivated the art of teaching with considerable success. Sunday schools have prospered in Scotland, where religious teaching alone ever prevailed, and the stability of this modern invention is accomplished.

The Sunday school found its way into Scotland as early as the year 1782; but it was not till 1786, when the Society for promoting Religious Knowledge among the Poor was formed, that it was publicly recognized; nor till 1797, when the Gratis Sunday School Society was originated, that schools became general. At first, they met with considerable opposition from portions of the ecclesiastical courts, but they are now supported by all the churches. Sunday School Unions exist in Edinburgh, Glasgow, and most of the large towns. The names of Dr. Chalmers, James Gall, the author of the *Lesson System*, and David Stowe, the author of the *Training System*, deserve mention in connection with the progress of Sunday schools in Scotland. In Ireland, Sunday schools had been partially anticipated in County Down in 1770; but it was not till 1785 that the system pursued by Mr. Raikes was adopted, since which, its history has been analogous to that of England. The Sunday School Society for Ireland was established in 1809. Sunday schools were introduced into New York in 1816, through the exertions of some benevolent ladies, from which they have spread themselves through the United States. They are now to be found wherever the English tongue is spoken. They thrive vigorously in the Protestant churches of France; and more recently have been planted in parts of Germany and Italy. The Roman Catholics, in this country at least, have numerous Sunday schools. It is stated on good authority that there are in the United Kingdom about 300,000 teachers and 3,000,000 scholars; and in the United States there are 750,000 teachers, and nearly 6,000,000 scholars. The centenary of the foundation of Sabbath schools was celebrated in 1880.

SU'NDERBUNDS, a tract of British India, presidency of Bengal, consists of a number of low islands, forming the delta of the Ganges. The tract extends east from the mouth of the Hoogly to the island Rabanabad, is 158 miles long, 75 miles broad, has an area of 5341 sq. m., and an inconsiderable population. The islands are separated from each other by narrow channels, through which the waters of the Ganges force their way to the sea. The chief channels (14 in number) are navigable for the largest craft used in inland navigation. In such of the islands as have not been cleared, luxuriant woods abound, and afford lairs for the tiger, wild boar, and other ferocious animals. Government have commenced vigorous operations for the clearing of the islands, and grants of land are offered to settlers at a nominal rate. The climate, though improving, and capable of further improvement, is, as might be expected, very unhealthy. Rice, sugar, and indigo are produced in the cleared districts. Large quantities of fish, obtained in the waters of the S., are sent to Calcutta. Large and fierce alligators abound in the channels.

SU'NDERLAND, a thriving municipal and parliamentary borough and seaport, in the county of Durham, 13 miles north-east of the city of that name, at the mouth of the Wear. The town may be said to be co-extensive with the parliamentary borough, and to include the suburbs of Bishop-Wearmouth on the south bank, and Monk-Wearmouth and Southwick on the north bank of the river, connected with S. proper by an iron bridge of one arch, 236 feet long, and nearly 100 feet above the river at low water. The bridge over the Wear was erected in 1796, but was repaired and widened in 1858 by Robert Stephenson (q. v.), at the cost of about £40,000. On both sides of the river there are extensive wet docks, much of the area of which has been reclaimed from the sea. The harbor, which is defended by batteries, is formed by two great piers, one 650 yards and the other 590 yards in length; and the port is resorted to by vessels of the largest tonnage, from all commercial countries. The exports (chiefly coal) have a value of above £700,000 per annum. After Newcastle, S. is the greatest coal-shipping port in the world. The sanitary condition of the town has been recently greatly improved; a large new infirmary was built in 1867, and in 1868 a spacious workmen's hall. Ship-building is one of the principal branches of industry. Glass, earthenware, ropes and chains, anchors, and other ironwares, are very extensively manufactured. The public park of S., about 70 acres in extent, is adorned with a bronze statue of General Sir Henry Havelock, a native of the town. The harbor and docks have been frequently improved, and in 1881 harbor extension was decided upon, at an estimated cost of £150,000. The village of Roker, a mile from the town, is much resorted to for sea-bathing. Fishing is carried on to a considerable extent. Pop. of parl. bor., which elects two members (1871) 104,409, mun. bor. 98,242; (1881) parl. bor. 124,960, mun. bor. 116,262.

SUNDERLAND, ROBERT SPENCER, second Earl, was the only son of HENRY, first earl, who had been raised to the peerage in 1643, for his exertions in the royal cause. He was born in 1642, and after serving as ambassador to several courts, became in 1679 Secretary of State. He had by this time manifested remarkable talent. Bishop Burnet says of him: 'He had a superior genius to all the men of business that I have yet known.' At first, he united with Essex and Halifax in opposing Shaftesbury, who wished to set Monmouth on the throne, and favored the exclusion of the Duke of York. He encouraged the king to persevere in the degrading French alliance, and, with the Duchess of Portsmouth, to whom he attached himself, negotiated a treaty by which, in consideration of an annual pension from the French king, Charles was to agree to assemble no parliament for three years. Before the end of a year, he had shaken off Essex and Halifax; and a new triumvirate, consisting of himself, Lord Hyde, and Godolphin, succeeded to the confidence of Charles II.

The treaty with France was broken off, and S., who was now afraid of the Whigs, engaged the king in a more popular alliance with Spain. After the dissolution of the last of the exclusion parliaments, he lost his office; but the duchess remained faithful to him in disgrace; and by her influence and that of Lord Rochester, he was, in 1682, says Bishop Burnet, 'upon great submission made to the Duke [of York], again restored to be Secretary.' He remained in office until the accession of James II., when his influence in the ministry became greater than ever. He who had so often saved himself in the former reign by the influence of the Duchess of Portsmouth, now secured himself another patroness in the king's second wife, the Princess of Modena. Although there is reason to believe he gave some encouragement to Monmouth in his rebellion, he managed, with consummate art, to obtain the entire confidence of James, and in 1685 became prime-minister. He was intrusted with a knowledge of the king's intention to establish the Roman Catholic religion as the national church, and was indeed the only minister in whom the king confided. In 1687, he privately conformed to the Roman Catholic Church, and afterwards openly professed his conversion. His influence was so great, that James would grant no favor until he had asked the question: 'Have they spoken to Sunderland?' and when told that this nobleman got all the money of the court, he would reply: 'He deserves it.' Yet we find him about this time in correspondence with the Prince of Orange, afterwards William III.

The Princess Anne described S. as 'the subtillest workingest villain that is on the face of the earth.' Burnet says he entered into a particular confidence with the Prince of Orange, which he managed by his uncle, Mr. Sidney, who was sent envoy to Holland. With profligate but masterly dexterity, he contrived to deceive both his master and Barillon, and to keep them in ignorance of the events that were passing in Holland. When the Prince arrived in England, S. and his wife went to Amsterdam, whence he wrote to the new monarch, claiming his favor and protection on the ground that he had all along been in his interest. In 1691, he was allowed to return to England, and to kiss the king's hand. In 1695, William III. spent a week at S.'s house at Althorpe. It was imputed to him that he had changed his religion, in the late reign, in order the more effectually to ruin King James; and it was generally believed that he had rendered King William, when Prince of Orange, some signal services, which no one else could have done. This belief gained credit from the favor shown him by William. He was made Lord Chamberlain, and as such took his seat at the head of the council table. After directing affairs as the acknowledged head of the government, he resigned office in 1697, and retired to private life. He spent the rest of his days at Althorpe, where he died in 1702. He never shone as a public speaker. He had, however, unusual abilities for business, and a rare skill in the art of insinuation. He possessed exquisite courtly talent, extraordinary versatility, and a flexibility of principle too common in his day, but carried by him to the most reprehensible lengths. By his wife, Anne, daughter of the second Earl of Bristol, he left CHARLES SPENCER, third earl, who was born in 1674. He was described by Evelyn as a youth of extraordinary hopes, very learned for his age, and ingenious. He was for some time Secretary of State in the reign of Queen Anne, and under George I. rose to be all-powerful; but in 1721, being accused of receiving £50,000 worth of the fictitious stock distributed by the directors of the South Sea Scheme (q. v.), in order to bribe the government, he was acquitted only by an inconsiderable majority and that from party considerations, and the indignation of the public made him resign his office. He died in 1722, not without suspicion of having intrigued, after his fall, for the restoration of the Tories, if not for the return of the Pretender.

S. was a type of the political morality, or rather immorality, of a disgraceful age, when the greatest statesmen made no scruple of sacrificing either their own party, or the interests and dignity of the nation, to personal ambition. His title descended to CHARLES, his second son, who succeeding, 1733, to the honors of his illustrious grandfather, John Churchill, the earldom of Sunderland became absorbed in the dukedom of Marlborough. His third son, JOHN, was ancestor of the Earls Spencer.

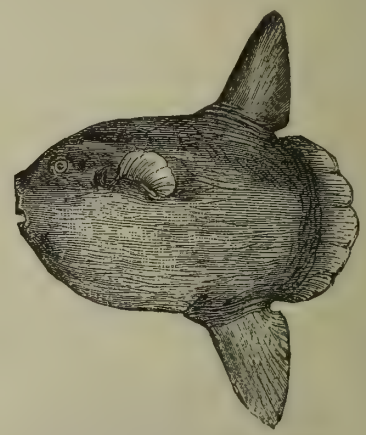
SU'NDEW (*Drosera*), a beautiful and interesting genus of plants of the natural order *Droseraceæ*, three species of which are natives of Britain, found in bogs and moist heathy ground. The most common is the ROUND-LEAVED S. (*D. rotundifolia*), which is plentiful in almost all places suitable to the plant. The leaves all spring from the root, and spread out in a rosette, from the center of which springs the flower-stem or scape, with a raceme of flowers all on one side. The leaves of this and the other species are fringed and beset in all parts with hairs, which bear at their extremity viscid glands, and the irritation of these glands causes them to contract and fold up, so that insects are imprisoned by them. Recent observation has proved that these insects are actually digested by the plant, their nutritive material being absorbed by it. Compare the *Dionæa* (q.v.), and see Darwin's *Insectivorous Plants* (1875). The whole plant is acrid, curdles milk and has a

Round-leaved Sundew (*Drosera rotundifolia*).

reputation for removing corns, bunions, and warts. An agreeable liqueur, called *Rossoli* (*Ros Solis*) is made by infusing the plant in brandy, with sugar, &c.

SUN-DIAL. See DIAL.

SU'NFISH (*Orthagoriscus*), a genus of fishes of the family *Diodontidæ* (see DIODON), having the body compressed, and not capable of inflation, as in the other *Diodontidæ;* abruptly terminating in a very short tail; the dorsal and anal fins long and pointed, united to the short tail-fin; each jaw furnished with a cutting edge of bone instead of teeth. The species chiefly inhabit the seas of warm climates, but two are occasionally seen on the coasts of Britain. The SHORT S. (*O. mola*), when young, is almost perfeetly round, but becomes rather more elongated when full grown. The name S. is variously regarded as derived from



Short Sunfish (*Orthagoriscus mola*).

the form of the fish, and from its habit of floating at the surface of the water, in fine weather, as if to enjoy the sunshine. It attains a large size, being sometimes more than six feet in length, and is captured by sailors. Its flesh is white and well flavored, somewhat resembling that of the skate. The liver yields a large quantity of oil, which is in repute among sailors as an external application for the cure of sprains, rheumatism, &c. The OBLONG S. (*O. oblongus*), of which specimens have also been taken on the British coasts, but more rarely, is of a longer form. It also attains a large size. The Sunfishes feed upon sea-weeds.

SU'NFLOWER (*Helianthus*), a genus of plants of the natural order *Compositæ*, suborder *Corymbiferæ*, having large flowers; the florets of the ray strap-shaped, without stamens or pistils, yellow or orange; the florets of the disc tubular, perfect, yellow or purplish brown; the flowers solitary or in corymbs, with an involucre of numerous leaves; the fruit compressed, with a pappus of two or more deciduous scales. The species are numerous, all natives of America; large herbaceous plants, with opposite or sometimes alternate undivided leaves. The ANNUAL S. (*H. annuus*), common in our flower-gardens, is a native of tropical America, where it sometimes attains a height of twenty feet. The stem is thick and rough; the flowers solitary, and from one foot to two feet in diameter, nodding; the leaves heart-shaped ovate. This plant is now cultivated in almost all parts of the world, and in the south

of Europe is sometimes a field-crop; the seeds being valued as food for cattle and poultry, and on account of the oil which they yield, which is little inferior to olive oil. An acre of good land produces about fifty bushels of seed, each bushel yielding a gallon of oil. The seeds are also used like almonds for making demulcent and soothing emulsions; and in some parts of Europe,

Sunflower (*Helianthus annuus*).

a bouilli is made of them, which is used as food for infants. The American Indians make bread of them. The flowers abound in honey, and are much frequented by bees. The leaves are good fodder for cattle. The stems are used for fuel, and yield much potash.—The Jerusalem Artichoke (q. v.) belongs to this genus.

SUNN (*Crotalaria* [q. v.] *juncea*), a leguminous plant, native of India, which has been in general cultivation there from time immemorial, for the fibre of its bark. It has a strong general resemblance to Spanish Broom. It is, however, an annual plant. The plant is cultivated not only for its fibre, but as food for milch-cows. The seed is generally sown in April or May, and in August it is pulled, or cut close to the ground—when grown for its fibre—laid in long rows till the leaves begin to rot and separate from the stalks, and steeped in water for a few days, till the bark separates freely. The fibre is not so strong as hemp; but good cables, canvas, and cloth are made of it. It is now imported in considerable quantity into Britain. It is known by various names. *Taag* is one of its Indian names, and it is sometimes called *Brown Hemp*, *Bengal Hemp*, &c. The confusion of names makes it difficult to ascertain the quantity imported.

SU'NNA (Arab. custom, legal usage), originally denotes among Muslims the sayings and the example of Mohammed and his community, provided they are in accordance with the Koran, the meaning of which, however, is itself explained by the Sunna. The term is therefore (though incorrectly) used for the collections of moral and legal traditions traced to the Prophet, which supplement the Koran, somewhat like the Mishna (q. v.), which supplements the Laws of the Pentateuch. The Sunna not only comprises religious doctrines and practice, but also civil and criminal laws, and the usages of common life: the way to eat and to drink, and to dress, and the like. This tradition is first heard of during the civil wars, among the adherents of the new faith, about half a century after the Flight. The single traditions, as we now possess them, rarely exceed six lines. The diction is carefully wrought, and the form is that of a dialogue. For the credibility and canonicity of a tradition, it was originally necessary that it should have been *heard* by one truthful witness; but this law was much relaxed in after-time. At the end of the 3d c. (H.), a countless number of individual collections (Mosnad), mostly of an apocryphal character, had been produced by different theologians, but the first who sifted them critically, and without regard to any special theological system, was Bochary (d. 256 H.). His collection contains 7275 single traditions, 4000 of which, however, occur twice in the work. Moslim, his pupil, supplemented Bochary with another collection, containing 12,000, again including 4000 repetitions. Besides these, there are four more 'canonical' collections; by Abû Dawûd (d. 275 H.), Tirmidzy (d. 279), Nasây (d. 303), and Mâga (d. 273). The Sunna, as we have it in these collections, contains, broadly speaking, more truth than it is generally supposed to contain, and, critically used, is, besides the Koran, the most authentic source of Islam. A selection from the different collections (both canonical and otherwise), called *Mishcat al Masabih*, has been translated into English by Captain Matthews (Calcutta, 1809). Fragments from Bochary are found in a German translation, by Hammer, in the *Fundgruben des Orients*.

SU'NNITES, traditionists or believers in the Sunna (q. v.); the name of the 'orthodox' Muslims, as opposed to the Shiites (q. v.). They are subdivided into four principal sects, who, though at issue on different minor points, yet are acknowledged, by each other, to belong to the Faithful, and to be capable of salvation, and they each have a special oratory at Mecca. The first of these sects are the Hanefites, founded by Abu Hanifa, who died 150 years after the Hedjrah. They are emphatically called 'the followers of reason,' whilst the other three are guided exclusively by tradition. They allow reason to have a principal share in their decisions on legal and other points. To this sect belong chiefly the Turks and Tartars. The second sect are the Malekites, founded by Malek Ibn Ans, who died about 180 H. at Medina. As one of the chief proofs of his real piety and humility, it is recorded that when asked for his decision on 48 questions, he would only decide on 16, freely confessing his ignorance about the others. In Barbary and other parts of Africa, the greatest part of his adherents are found. Mohammed Al Shâfeï, born in Palestine, 150 H., but educated in Mecca, is the founder of the third sect, the Shâfæites. He was a great enemy of the scholastic divines, and seems altogether to have been of an original cast of mind. He never swore by God, and always took time to consider whether he should at all answer any given question or hold his peace. The most characteristic saying recorded of him is: 'Whosoever pretends to love both the work and the Creator at the same time, is a liar.' He is accounted of such importance, that according to his contemporaries, 'he was as the sun to the world, and as health to the body;' and all the relations of the traditions of Mohammed were said to have been asleep until he came and woke them. He appears to have been the first who reduced Muslim jurisprudence into a method, and thus made it, from a number of vague sayings, a science. His followers are now chiefly found in Arabia and Persia. Ahmed Ibn Hanbal founded the fourth sect, the Hanbalites. He was born 164 H., and was a most intimate friend of Shâfeï. His knowledge of the traditions (of which he could repeat no less than a million) was no less famed than was his piety. He taught that the Koran was not created, but everlastingly subsisted in the essence of God; a doctrine for which he was severely punished by the Calif Al-Motasem. On the day of his death, no less than 20,000 unbelievers (Jews, Christians, and Magians) are said to have embraced the Mohammedan faith. Once very numerous, the Hanbalites now are but very rarely met with out of Arabia. On the differences between the S. and Shiites, see SHIITES.

SUN-STROKE (otherwise called *Heat Apoplexy*, *Heat Asphyxia*, *Coup de Soleil*, *Erythismus tropicus*, and *Insolatio*, the name by which it is officially known in the returns of the Registrar-general) is a very fatal affection of the nervous system, which seldom occurs in Great Britain, except in extremely hot summers, but is very common in India and other tropical countries. Our knowledge of the nature of this remarkable disease is almost entirely based upon the accounts which have been given of it by Indian medical officers. It is from their reports that the most satisfactory history of this disease at present published—that, namely, of Dr. Aitken in his *Science and Practice of Medicine*, 3d ed. 1864—is mainly drawn up. From the accounts given by these observers, it is clear that the symptoms of the disease are liable to be greatly modified in different cases. Mr. Russell, when in charge of the 68th Regiment in May 1834, shortly after its arrival at Madras, with the men in robust health, has given the following account of this disease. 'The funeral of a general officer being about to take place, the men were marched out *at an early hour in the afternoon, buttoned up in red coats and military stocks, at a season, too, when the hot land winds had just set in*, rendering the atmosphere dry and suffocating even under the shelter of a roof, and when the sun's rays were excessively powerful. After having proceeded two or three miles, several men fell down senseless. As many as eight or nine were brought into hospital that evening, and many more on the following day. Three men died—one on the spot, and two within a few hours.

The symptoms observed (and they were alike in the three cases) were, first, excessive thirst, and a sense of faintness; then difficulty of breathing, stertor, coma, lividity of the face, and in one whom Mr. Russell examined, contraction of the pupil. The remainder of the cases (in which the attack was slighter, and the power of reaction perhaps greater) rallied; and the attack in them ran on into either ephemeral or a more continued form of fever.' Aitken, *op. cit.* One of the earliest symptoms, noticed by several observers, is the skin becoming rough and scaly, and the perspiration ceasing; the heat of the surface becomes at the same time much increased; the bowels become obstinately constipated. The actual attack, in the various cases described by the Indian surgeons and physicians, came on generally when the men were in their tents, sometimes during the day, but in several cases during the night. The patient had been generally lying down, often seemingly asleep, when the attention of his comrades would be directed to his hurried and heavy breathing, and on attempting to rouse him, he was found to be insensible. The mortality from sun-stroke is about 50 per cent. In the cases that terminate favorably, a gradual remission of the symptoms takes place; and

when the skin becomes cool and moist, and sleep has been procured (phenomena which usually occur within 36 hours of the attack), the patient may be regarded as out of danger.

The prediposing causes of sun-stroke are (1), an unusually elevated degree of temperature, accompanied by great dryness of the air; (2) The electrical condition of the atmosphere that precedes a thunderstorm; (3) A contaminated atmosphere from overcrowding; (4) All debilitating causes, such as prolonged marches, previous disease, intemperate habits, &c. Death sometimes occurs so suddenly that there is little opportunity for treatment, but the general indications in these cases are—the cold douche, from a height of three or four feet, keeping the surface wet and exposed to a current of air, the exclusion of light as far as possible, and the free employment of stimulants. In less rapidly fatal cases, the outer clothing should be removed, and the douche applied, as before, over the head and along the spine. Relaxation of the pupil is the first favorable sign. If the pulse flags, the douche must be replaced by the mere application of cold to the head. The hair must be cut as short as possible, and the nape of the neck blistered as speedily as possible. If insensibility recurs after an interval of ten or twelve hours, a blister should be applied to the crown of the head. The extremities and chest should be stimulated with mustard poultices. Immediately after the employment of the douche, a strong purgative injection should be thrown up the lower bowel, by means of a long stomach-pump tube (as, for example, a mixture of an ounce and a half each of castor oil and oil of turpentine, and two drachms of tincture of asafœtida in about half a pint of barley-water). Under no circumstances, should there be any abstraction of blood. The preventive measures are of more importance than the treatment; but this is a subject into which we have not space to enter. The advice of the regimental surgeon is too often disregarded by the commanding officer. There was an extraordinary mortality from sunstroke in the United States in the hot summer of 1881 : of 583 deaths occurring in little more than a week in Cincinnati, 314 were reported as being due to sunstroke and other heat-effects.

SUONADA (inland sea), an inland sea of Japan, which separates the island of Kiusiu and Sikopf from the larger one of Nipon. It is about 250 miles in length from the strait of Simonoseki to Osaca; and Sir R. Alcock estimates its greatest breadth at 50 miles. It is studded with innumerable islets and a few rocks. The scenery is picturesque. The prince of Nagato and Soulio having, contrary to treaty stipulations, closed this sea to foreign vessels and fired upon them, the English, French, and Dutch fleet destroyed the forts that barred its entrance (5th and 6th September 1864), with the loss, to the allied squadron, of 12 men killed and 60 wounded.

SUPERANNUA'TION is a retiring allowance granted under an act of 1859, 22 Vict. cap. 26, to all persons not being weekly laborers employed permanently in the civil service of the country. Before the age of 60, retirement can only take place from broken health (or ostensibly so), or from abolition of office : after 60, any person may retire. If the retirement take place before completing ten years' service, a gratuity only is allowed. After ten years, the pension is $\frac{1}{60}$th of the salary at the time of retirement for every year of service, up to $\frac{40}{60}$ths, which is the maximum allowed, except under very special circumstances, when the Treasury may grant larger pensions, never, however, exceeding the salary vacated. Professional persons appointed later in life than the usual age, may have pensions computed with a number of years, not exceeding 20, added to their actual service. On the other hand, the Treasury may, for grave demerit, diminish a pension below the scale granted in the act. A person on a pension is liable to recall to a position as good as he vacated, up to the age of 60, if in suitable health. A civil servant is defined to be one holding appointment direct from the crown, or under certificate from the Civil Service Commissioners; and his salary must be paid out of the consolidated fund or out of moneys voted by parliament. Weekly laborers are ineligible; but artificers may serve for superannuation, provided they are not paid at the full current market rates of wages. See RETIREMENT.

Superannuation is one of the great boons of the permanent civil service, in which the officials are, as a rule, paid salaries lower than they could earn elsewhere; but to render promotion tolerably certain, retirement at 60 should be, not as now voluntary, but compulsory. At present, an official may at his option serve as long as he is capable of attending office; and many actually do die in harness, years after they have become useless.

SUPERCA'RGO is an important officer in a merchant vessel, charged with the control of all her commercial transactions. The cargo is under his care, and he judges as to its disposal and replacement.

SUPEREROGA'TION, WORKS OF (Lat. *Supererogata*, over and above things required), a class of works which, in the Roman Catholic system, are described as not absolutely required of each individual as conditions to his eternal salvation. Roman Catholics found this definition on the distinction between what they believe to be commanded and what they hold to be only counselled, for an example of which they appeal to the words of our Lord to the young man in Matthew xix. 21, which distinguish one class of works which are necessary in order to 'enter into life,' and a further class which must only be done if we 'would be perfect.' Roman Catholics do not profess to recognize in works of supererogation, any distinctive essential quality by which they differ, whether in their physical or their moral entity, from other works, and in virtue of which, by their own nature, the individual may found upon them a personal claim to reward. For works of supererogation, as for all supernaturally good works, they hold that the assistance of God's grace is indispensably necessary; and they do not ascribe to them any merit, except that which arises from God's own free and gratuitous promise. In one word, the only distinctive characteristic of a work of supererogation lies in its not being supposed to be prescribed or commanded as absolutely necessary for the salvation of the individual, and its being done for the sake of greater perfection; and the doctrine which teaches the possibility of such works is, according to Catholics, a necessary consequence of the unequal fervor and unequal degrees of holiness which exist even in the class of the virtuous servants of God.

A further consequence of this doctrine is that God may accept the superabundant works of one in atonement for the defective service of another; and hence, in the Catholic theory of Indulgences (q. v), along with what they regard as the infinite and inexhaustible treasure of the merits of our Lord, they also regard, although in a degree infinitely inferior, the superabundant merits of the saints as forming part of that 'treasure of the church' which is applied in the form of indulgences.

SUPERFŒTA'TION, or the circumstance of two distinct conceptions occurring in the same woman at an interval of greater or less duration, so that two fœtuses of different ages—the offspring possibly of different parents—may co-exist in the uterus, is a subject of great interest both in a scientific and in a medico-legal point of view. A couple of centuries ago, there was a universal belief in not only the possibilty but the comparative frequency of this occurrence. Fifty years ago, it was as universally disbelieved; and now again (owing to the investigations of various inquirers, amongst whom Dr. Bonnar of Cupar deserves special mention), we are returning to the belief of our ancestors. The cases described as instances of superfœtation may be arranged in three classes; but as will be presently seen, it is only to the cases of the third class that the term superfœtation is truly applicable. The *first class* includes the numerous undisputed cases in which two mature children, bearing evidence from their different colors, that they are the offspring of different parents, are born at the same time. In the slave states of America, it was by no means uncommon for a black woman to bear at the same time a black and a mulatto child—the former being the offspring of her black husband, and the latter of her white lover; and the converse has occasionally occurred—a white women at the same time bearing a white and mulatto child. There is no difficulty in accounting for these cases, which are examples of contemporaneous conception rather than true superfœtation.

The *second class* includes those cases in which a twin has been aborted, leaving its fellow undisturbed in the uterus, to be matured and born in due time, or in which twins have been produced at the same time, one of which was fully formed, while the other was small and apparently premature, from being 'blighted' or arrested in its development at an early period. Cases of these kinds are by no means rare; but there is no reason for believing that the infants were conceived at different periods. The *third class* includes the cases in which a *mature* child has been born, and an *immature* fœtus, the product of a different conception, has either been left in the womb until its period of maturation, or, if expelled along with the other, has presented no mark of wasting or of arrested development. 'In a case of genuine superfœtation,' says Dr. Bonnar, 'a woman must bear two (or more) *mature* children, with an interval of weeks or months between the birth of each; or, if she part with the whole contents of the uterus at the first delivery, the difference of the ages of the fœtuses, or the mature child and the fœtus as the case may be, must be unmistakable, and there must be the absence of all marks of blight of the latter, so as to leave no doubt that, had it remained in utero, it would have gone on to perfect maturity.' Amongst the cases of superfœtation that have been specially discussed by writers on Midwifery and Medical Jurisprudence, are the following : (1) Velpeau quotes from the *Recueil de la Société de Médecine* the case of a woman named 'Arles,' who, in 1796, gave birth to a child at the full time, and five months afterwards to another, which was also thought to be at the full time; (2) Dr. Maton, an eminent London physician, communicated to the College of Physicians the case of Mrs. T——, an Italian lady, who was delivered of an apparently healthy and mature male child on

the 12th of November 1807, but which lived only nine days. On the 2d of February 1808, or 82 days after the birth of the first, she was delivered of a second child, which likewise had every sign of being completely formed and mature.

The following case, which, as Dr. Bonnar (in his *Critical Inquiry regarding Superfœtation*, Edin. 1865) observes, 'has been the principal battle-field of the advocates of superfœtation and their opponents,' and has given rise to more discussion than any other, is recorded by Dr. Desgrange of Lyon. Madame Villard had a miscarriage at seven months on the 20th of May 1779. In about a month thereafter, she conceived again, and on the 20th of January 1780, she brought forth a living child. No milk appeared in her breasts, the abdomen did not seem to diminish in size, and other symptoms which normally follow delivery were absent. The two surgeons who were in attendance being naturally puzzled, called in Dr. Desgrange, who declared, in opposition to their views, that there was still a child in the womb; and his opinion was confirmed by her being delivered of a living child on the 6th of July 1780, 167 days after the first birth. Dr. Bonna has collected from *The Peerage* a number of cases of probable superfœtation occurring in married life. Excluding a very few exceptional cases, he adopts Dr. William Hunter's view, that 210 days, or seven calendar months, is the minimum period of uterine life at which a child should be born in order to be reared, and he assumes that no prolific intercourse can take place until at least fourteen days after the first delivery; and with these axioms, he quotes the following cases: (1) In the Hamilton (Lord Mountflorence) family, a daughter, who was born 182 days after the birth of a son who had reached maturity, lived to be married, whose supposed uterine life was not more than 168 days. (2) In the Aukland family, the Honorable William Frederick Eliot, who was born 173 days after the birth of a sister (who lived 60 years), survived 28 years, although his assumed uterine life was only 159 days. (3) Lord Cecil J. Gordon, brother to the 10th Marquis of Huntly, has a son, Cecil-Crosbie, who was born in January 1850 (only 127 days after the birth of a previous child). This son came to maturity, and his assumed period of gestation was only 113 days. 'We cannot conceive,' says Dr. Bonnar, 'how these three cases can possibly be explained except by the doctrine of superfœtation;' and Dr. Taylor (*Principles and Practice of Medical Jurisprudence*, page 849) fully adopts his view. Dr. Duncan believes, from anatomical investigations, that up to the third month of gestation, a second conception may follow the first; and he is of opinion that this will satisfactorily account for all the cases of superfœtation on record.

SUPE'RIOR, in Scotch Law, means one who, or whose predecessor, has made a grant of heritable property to a vassal, on condition of the latter paying an annual duty or sum of money, generally called a feu-duty. The superior is said to have the superiority, or *dominium directum*, and the vassal has the feu, or *dominium utile*. In popular language, the superior is a kind of landlord. See FEU.—In England, the word is not used, though in copyhold estates the term 'lord' corresponds to it.

SUPERIOR, LAKE, the largest body of fresh water in the world, is the highest and most western of the great lakes lying between West Canada and the United States. It is situated not far from the center of the North American continent. Its general form is nearly semi-lunar, the outer curve being towards the north. Greatest length from east to west, 355 miles; greatest breadth, 160 miles; area, about 32,000 sq. m.—fully that of Ireland. The surface of the lake is about 600 feet above the level of the sea, and its mean depth 1000 feet, so that its bottom is 400 feet below the level of the seal It surface has an elevation of about 22 feet above that of Lake Huron and Lake Michigan. The greater portion of this rise is at the Sault Ste. Marie, a strong rapid about a mile in length, at the commencement of the river St. Mary, which transmits the waters of Lake S. to Lake Huron.

Lake S., being situated very near the watershed between Hudson's Bay and the Mississippi, receives no rivers of importance, although hundreds of small rivers pour themselves into it. The largest are the St. Louis River, which falls into its western extremity at Fond du Lac, and is about 110 miles long; and the Neepigon River, on the north side, which, with the lake of the same name has a length of about 200 miles. One of the branches of the Mississippi in Minnesota approaches to within 20 miles of the western extremity of Lake S.; and a small lake near the head of the Albany River, of which the waters flow to Hudson's Bay, is only four miles from a bay opposite the State Islands on the northern shore, forming a route with little portage, which has long been used by the Hudson's Bay Company for the conveyance of goods from Lake S. to the northern country.

The promontory, Kee-wee-naw, near the middle of the south side, projects far into the lake. The islands are not numerous, the largest being Isle Royale, 44 miles long.

The country around Lake S. is generally bold and hilly, with the exception of the peninsula lying between it and Lake Michigan; but few of the hills rise more than 1000 feet above the level of the lake, and most of them are far below this height. On the southern shore, 100 miles west of the Sault Ste. Marie, are the Pictured Rocks, cliffs of gray and red sandstone from 100 to 200 feet high, in many places presenting fantastic forms, and marked by numerous perpendicular stripes of red and yellow, from ferruginous waters trickling down the face of the rock.

The boundary between the United States and W. Canada, starting from the outlet of the lake at the Sault Ste. Marie, sweeps towards the north, so as to include in the United States even the Isle Royale, which is only 13 miles from the British coast, and strikes inland from the mouth of Pigeon or Arrow River, on the north-west shore.

The only obstacle to navigation between Lake Huron and Lake S., is the Sault Ste. Marie, which is overcome by a canal of about a mile in length, with two locks, on the American side. This is, perhaps, the finest canal in the world. The sides and bottom are lined with stone throughout its whole length, the locks are admirably contrived, and the largest ships can pass through it with ease. The trade is increasing so rapidly, that a canal on the British side will also be required at no distant day.

The water of Lake S. is remarkable for its coldness, purity, and transparency, although the affluents on both sides are either turbulent, or deeply colored by vegetable matter from swamps and forests.

A rise or fall in the level of the water, amounting to several inches in a few hours, is frequently to be observed along the shore, and has been supposed to be due to a regular tide, but is probably caused by the wind. Fresh water being more easily moved by the wind than salt water, great waves arise in Lake S. with wonderful rapidity; and even in summer, large steamers are compelled to take shelter in some bay, or under the lee of an island. Owing to the low temperature of the water, compared with that of the air, in summer, fogs are prevalent, resting on the water at night, and vanishing an hour or two after sunrise.

Lake S. never freezes over, but the bays are sealed up in winter, and a rim of ice extends to some distance all around the shore.

The rocks around the lake are very ancient, belonging principally to the Laurentian and Huronian systems of the Azoic series, overlaid in some places, especially on the south side, with patches of the Lower Silurian. The prevalent Laurentian rock is orthoclase gneiss. Among the Huronian rocks are greenstones, slates, conglomerates, quartzites, and limestones. The Lower Silurian rocks are soft sandstones. There is everywhere much evidence of glacial action.

The Huronian rocks are well stored with useful minerals. The copper and iron mines of the south side are celebrated for their extent and richness, and there is every reason to think that the mineral resources of the British side are equal to those of the American, although as yet comparatively undeveloped. The richest copper-mines are situated near Kee-wee-naw Point. The metal occurs principally native, and sometimes in single masses of great size. One was met with in 1853, which measured about 40 feet in length, and was calculated to weigh about 400 tons. Native silver is found associated with the native copper, and sometimes intimately mixed with it. A rich vein in an islet in Thunder Bay (British side) yielded in one year silver to the value of 1,230,000 dollars. Gold has been found in small specks at Namainse on the British side. Lead ore occurs in some places. The beds of hæmatite, or red iron ore, at Marquette, on the south side, are of wonderful extent. The ore is conveyed by a railway to the harbor, thence by vessels to Cleveland, on Lake Erie, and thence by rail to Pittsburg, where it is smelted.

The fisheries of Lake S. deserve notice. The delicious whitefish and the gray trout abound, as well as other kinds of fish. The Canadian legislature passed a law in 1865 to put a stop to the wholesale destruction of them on the spawning grounds.

The shores of Lake S. are frequented by bands of the Ojibbeway tribe of aborigines. They are of very pure blood, retain in a great measure their primitive habits, and many of them are still pagans.

The white population of the British shore of Lake S. consists as yet only of the fishermen and explorers who visit the region during summer; and of miners who extract the silver ore from veins recently discovered on Silver Island, near Thunder Bay. But on the American shore, a number of thriving towns have sprung up. Until the completion of the Canadian Pacific Railway along its northern shore, the connection between the eastern and western sections will be formed by steamboats across the lake, from the Ottawa section at Sault Ste. Marie on the east side, to Prince Arthur's Landing on the western shore. A telegraph line has been established.

SUPERPHO'SPHATES. See PHOSPHORUS.

SUPERTO'NIC, in Music, the note which, in the diatonic scale, is next above the tonic or keynote, and forms with it the interval of the second, as D in the key of C major.

SUPPLE JACK, a name given in the southern parts of the United States of America to the *Berchemia volubilis*, a twining shrub of the natural order *Rhamnaceæ*, which is found as far north as Virginia. It has oval leaves, small flowers, and violet-colored berries. It abounds in the Dismal Swamp and in similar situations, and ascends to the tops of the highest trees. The genus *Berchemia* contains a number of species of twining shrubs, natives of warm climates in different parts of the world.—The name S. J. is also given in the West Indies and tropical America to *Serjania* (or *Seriana*) *triternata*, a shrub of the natural order *Sapindaceæ*, with a long, flexile, woody stem, which climbs to the tops of the highest trees, and is used for walking-sticks. It has poisonous properties, and is employed for stupefying fish.

SUPPLY', COMMISSIONERS OF, persons appointed by the acts imposing the land-tax in Scotland, to assess, and formerly also to collect, that tax. Their principal duty now is to assess the land-tax, and apportion the valuation according to the provisions of the Valuation of Lands Act, 17 and 18 Vict. c. 91. They are entitled to name a convener, who acts as preses of the meeting, and a clerk with a reasonable salary. The qualification, as recently modified by 17 and 18 Vict. c. 91, consists in the being named as an *ex officio* Commissioner of Supply in any act of supply; or the being proprietor, or husband of a proprietor, of lands of the yearly value of £100; or the eldest son of a proprietor of lands of the yearly value of £400: and a factor of a proprietor of lands of the yearly value of £800 is empowered to act as Commissioner of Supply in his absence.

By act 17 and 18 Vict. c. 91, the Commissioners of Supply of every county, and magistrates of every burgh, must cause a valuation roll to be made up yearly, showing the rents of all lands or heritages in the county or burgh, and the names of the proprietors and tenants; and for this purpose, they are empowered to appoint an assessor or assessors. A yearly court is to be held by the commissioners and magistrates, for hearing appeals against the determinations of the assessors, in which three Commissioners of Supply and two magistrates are to form a quorum, the preses having a casting vote. See VALUATIONS OF LAND, LAND-TAX.

SUPPLY, COMMITTEE OF. The sums granted in parliament to defray the public expenditure for the current year are called *Supplies*. All bills authorizing the expenditure of public money must originate in the House of Commons, and be based on resolutions moved in a Committee of Supply, which is always a committee of the whole House. The House having resolved that a supply be granted to her Majesty, resolves itself into a Committee of Supply. The various estimates are submitted to the committee, which has to consider what specific grants are to be voted; and the resolutions of the committee are reported to the House, and adopted or rejected. It belongs to another committee of the House, the 'Committee of Ways and Means,' to consider how the sums shall be raised which are voted by the Committee of Supply. See WAYS AND MEANS, PARLIAMENT.

SUPPO'RTERS, in Heraldry, figures placed on each side of an armorial shield, as it were to support it. They seem to have been, in their origin, a purely decorative invention of medieval seal-engravers, often, however, bearing allusion to the arms or descent of the bearer; but in the course of time, their use came to be regulated by authority, and they were considered indicative that the bearer was the head of a family of eminence or distinction. The most usual supporters are animals, real or fabulous; but men in armor are also frequent, and Savages (q. v.), or naked men, often represented with clubs, and wreathed about the head and middle. There are occasional but rare instances of inanimate supporters. On early seals, a single supporter is not unfrequent, and instances are particularly common of the escutcheon being placed on the breast of an eagle displayed. The common rule, however, has been to have a supporter on each side of the shield. The dexter supporter is very often repeated on the sinister side, but the two supporters are in many cases different: when the bearer represents two different families, it is not unusual for a supporter to be adopted from the achievement of each.

In England, the privilege of bearing supporters as now defined belongs to the sovereign and princes of the blood, peers and peeresses, and the heads of a very few families not of the peerage, whose right is based on an ancient patent, or very early usage. No right is recognized by the College of Arms as belonging to the sons of peers bearing courtesy titles. Knights of the Garter and Knights Grand Cross of the Bath are dignified with supporters, which, however, are not hereditary. Supporters have also been assigned to the principal mercantile companies of London. In Scotland, the use of supporters is somewhat less restricted. The distinction was much less wide than in England between the greater and lesser barons (see MINOR BARONS), and the right to supporters was considered to belong to the latter, so long as the baronial status conferred a right to sit in parliament. The act of 1587, which finally excluded the lesser barons from the Scottish parliament, and established a systematic parliamentary representation, was not held to interfere with this armorial privilege, and it is yet the practice of the Lord Lyon to grant or confirm supporters to the representatives of all minor barons who had full baronial rights prior to that date. A limited number of heads of important families, including the chiefs of the larger Highland clans, apart from considerations of barony, participate in the right to supporters. Lyon is also considered to have it in his power to confer them *ex gratiâ*, a prerogative which is but sparingly exercised, one of the instances of such departure from strict rule having been in favor of Sir Walter Scott. Nova Scotia baronets as such have no right to supporters, though many of them bear them in respect of their baronial qualification.

Arms of Duke of Argyll.

The lion and unicorn, familiar in the royal arms of the United Kingdom, were adopted, the former from the achievement of England, the latter, from that of Scotland prior to the union of the crowns.

In the more modern heraldry, supporters generally stand either on an escrol, containing the motto, or, more properly, on a carved panel of no definite form, which in Scotland is known by the name of a *compartment*.

SUPPURA'TION is a morbid process which gives rise to the formation of Pus (q. v.), which, as is well known, is one of the commonest products of inflammation. There are two doctrines as to the origin of pus. The opinion universally adopted till very recently was, that it was formed from an excessive exudation of the fluid portions of the blood through the walls of the capillaries; in which exudation, under certain conditions, pus-cells were developed. This view is now rejected for the doctrine of Virchow, the eminent professor of pathology at Berlin, who maintains that pus-cells are generated from the corpuscles of areolar tissue, which he supposes to permeate nearly every portion of the body. Pus, according to Virchow, is a young tissue in which, amidst the rapid development of cells, all solid intercellular substance is gradually dissolved. A single cell of areolar or connective tissue may, in an extremely short space of time, produce some dozen of pus-cells; but the result is of no service to the body, suppuration being, to use his own words, 'a pure process of luxuriation, by means of which superfluous parts are produced, which do not acquire that degree of consolidation or permanent connection with one another, and with the neighboring parts, which is necessary for the existence of the body.' There are two different modes of pus-formation, according as the pus proceeds from Epithelium (q. v.) or from connective tissue (see CELLULAR TISSUE). When pus is formed from epithelium, it is produced without any considerable loss of substance, and without ulceration; but when it is formed from connective tissue, ulceration must always exist. The mucous membranes vary in their power of forming pus.

A mucous membrane, according to Virchow, is the more qualified to produce pus without ulceration the more completely its epithelium is stratified, those with a single layer of epithelium being less adapted for the production of pus. Thus the intestinal mucous membrane scarcely ever produces pus without ulceration; while other mucous membranes, containing several strata of cells, are capable of secreting enormous quantities of this fluid without the slightest ulceration (as, for example, the urethral mucous membrane in gonorrhœa).

The above cases of suppuration occur on free or exposed surfaces, and are unaccompanied with loss of tissue. Deep-seated pus-formation takes place only in connective tissue. The first stage of formation consists in an enlargement of the normal cells, and a division and excessive and rapid multiplication of their nuclei. This is soon followed by division of the cells themselves, and their conversion into true pus-cells. If this process takes place beneath a surface which does not participate in the morbid change, or which is capable of resisting it for a time, an *abscess* is formed; whereas, when pus-cells are poured forth from an exposed surface, we have an *ulcer*.

Although suppuration is a morbid process, it often accompanies processes of a beneficial tendency (such as granulation), and frequently takes the place of other far more morbid processes. It further affords a mechanical means of removing foreign bodies,

such as thorns, splinters of glass, &c., from soft parts into which they may have been driven; and it is possible (as some pathologists believe) that the formation of abscesses may sometimes serve to eliminate morbid matters from the system.

SUPRALAPSA'RIAN (Lat. *supra*, before, *lapsus*, the Fall), the name given to the school of divines which maintain that God's absolute decree of election and reprobation is antecedent to His foresight of the fall of Adam, and irrespective of it. See SUBLAPSARIAN.

SUPRA-RE'NAL CAPSULES AND THEIR DISEASES. The supra-renal capsules are two small, flattened, glandular bodies of a yellowish color, situated, as their name implies, immediately in front of the upper end of each kidney. In weight they vary from one to two drachms. They belong to the class of ductless glands, and on making a perpendicular section, each gland is seen (like the kidney) to consist of cortical and medullary substance. The blood-vessels and nerves of the glands are exceedingly numerous. Of late years, much attention has been drawn to the diseases of these organs from the observation of the late Dr. Addison (of Guy's Hospital), that such cases are frequently associated with the deposition of pigment in the skin, causing it to assume a deep bronze color. The following definition of *Addison's Disease*, or *Supra-renal Melasma*, or *Bronzed Skin Disease*, embracing all the most important points in its natural history, is given by Dr. Aitken: 'A morbid state, which establishes itself with extreme insidiousness, whose characteristic features are anæmia, general languor and debility, and extreme prostration, expressed by loss of muscular power, weakness of pulse, remarkable feebleness of the heart's action, breathlessness upon slight exertion, dimness of sight, functional weakness and irritability of the stomach, and a peculiar uniform discoloration of the skin, which becomes of a brownish olive-green hue, like that of a mulatto, occurring in connection with a certain diseased condition of the supra-renal capsules. The progress of the disease is very slow, extending on an average over one year and a half, but may be prolonged over four or five. The tendency to death is by asthenia, the heart becoming utterly powerless, as if its natural stimulus—the blood—had ceased to act.'—*The Science and Practice of Medicine* (3d ed. vol. ii. p. 72). The numerous cases recorded by different physicians of all countries since Dr. Addison's original observations were made, show that the connection between *bronzing* of the skin and various morbid states of the supra-renal capsules is a fact beyond all dispute; but the exact relationship and pathological significance of the morbid states thus connected are still open questions. The special morbid changes in the capsules necessary for the production of the symptoms which constitute the disease, are first the deposition of a translucent, softish substance; the degeneration of this to a yellowish-white opaque matter; and afterwards a softening into an abscess, or drying up into a chalky mass. In the way of treatment, nothing can be done but to attempt to improve the general health by nourishing food, tonics, &c. The literature of this very singular disorder is mainly to be found in various memoirs in the *Guy's Hospital Reports*.

SUPRE'MACY, ROYAL. The term supremacy is, in politics, chiefly used with regard to authority in matters ecclesiastical. From the time of Pope Gelasius (494 A.D.) to the Reformation, the pope exercised a very extensive authority, judicial, legislative, and executive, over all the churches of Western Europe, somewhat undefined in its limits, varying in different countries and at different periods; which continues to be more or less recognized in all countries whose inhabitants are in communion with the Church of Rome. At the English Reformation, the papal supremacy was abolished, and act 26 Henry VIII. c. 1, declared the king and his successors to be the 'only supreme head on earth of the Church of England.' A curious document was at the same time drawn up by the government, in which, to avoid misconception, it was explained that the recognition of this headship of the church implies only that the king should have such power as of right appertaineth to a king by the law of God, and that he should not take any spiritual power from spiritual ministers, or pretend to 'take any power from the successors of the apostles that was given them by God.' In 1535, the same year in which this act was passed, John Fisher, bishop of Rochester, Sir Thomas More, and others, were beheaded for denying the king's supremacy; and in 1578, John Nelson, a priest, and Sherwood, a young layman, suffered the punishment of death for the same offence. The assumption by Henry VIII. of the title of 'Head of the Church,' notwithstanding the explanation alluded to, was much commented on; and on the accession of Elizabeth, it was thought prudent, while again claiming the supremacy in all causes, as well ecclesiastical as civil, to keep that designation in the background. By successive statutes, the oath of supremacy was appointed to be taken by the holders of public offices along with the oath of allegiance and of abjuration, and these three oaths were consolidated into one by 21 and 22 Vict. c. 48. The subject of oaths was, however, revised by the legislature in 1868 and 1871; and a new short oath of allegiance, in which the royal supremacy in matters ecclesiastical is not in express words specified, was substituted for the oath previously imposed upon members of both Houses of Parliament. See ABJURATION and OATH.

SURABAY'A, a leading seaport of Java, and capital of a residency, is situated on the Kali Mâs mouth of the river Kedirie, near the Strait of Madura, the citadel being in 7° 4′ 30″ S. lat., and 112° 40′ 40″ E. long. The population of the city and suburbs is about 110,000. The European town is on the west bank, five bridges connecting it with the Chinese and Javan quarters on the east. There are 2 Protestant clergymen, a Roman Catholic priest and assistant, several government and adventure schools for Christian children. There are regular steamboat services to Samarang, Batavia, and other places. The government sugar-culture in S. employs 6000 families, and produces above 30,000 tons per annum. The government coffee amounts to about 400 tons per annum. The residency of S. comprises an extensive tract of fertile land in the north-east of Java, and the island of Madura. The population amounts in all to 1,600,000, including 5500 Europeans and 11,000 Chinese. Rice, coffee, sugar, indigo, cotton, tobacco, and cocoa-nuts are extensively cultivated.

SURAKA'RTA, a residency of Java, south-east from Samarang, with an area of 2370 sq. m., is fertile and well cultivated, producing rice, maize, sugar, coffee, tea, indigo, tobacco, pepper, cacao, vanilla, and tropical fruits. About 4500 tons of coffee are produced yearly. Pop. 830,000, including about 2000 Europeans. The people are proud, and less obedient than in the other residencies, but abjectly submissive to the native emperor, though, in many things connected with his government, he must consult the European resident.

Surakarta, the capital of the empire, and seat of the residency, lies on the left bank of the Solo, in 7° 31′ 30″ S. lat., and 110° 46′ 7″ E. long., covers a large space, and has a population of over 50,000. Many princes and nobles have their palaces in S.; that of the emperor is of great extent and splendor, 10,000 persons, belonging to, or in the service of the royal family, living within the wall. North-east from the royal parks lies the European town, in front of which, surrounded by the parade ground, and commanding the palace, is a square fort, with broad canal and drawbridges at the four curtains, and mounted with 30 pieces of heavy artillery. There is a normal school for training Javanese teachers; a government school, with 80 pupils; and an adventure girls' school, with 40 pupils. A railway was completed in 1870, from Samarang to S., by which the produce is easily conveyed to the port of shipment, and an impulse given to trade and agriculture.

SURA'T (Sans. *Saurashtra*, good country), a large but declining city of British India, capital of a district of the same name, 150 miles north of Bombay, and about 17 miles from the mouth of the Taptí, in the Gulf of Cambay. It is 6 miles in circumference, and it is surrounded on the landward side by a brick wall. The river at S. is said to be fordable, although at high tide it can float vessels of 50 tons burden. The English and Portuguese factories, the former now used partly as a lunatic asylum and partly as hospital, are both imposing edifices of great strength and solidity. S. is said to have contained—but this is probably an exaggeration—800,000 inhabitants at the close of the 18th c., about which time its markets were crowded with the costliest wares, brought by merchants from the remotest countries. Its trade and manufactures, once almost extinct, revived during the American civil war, and it still exports cotton and grain to Bombay. S. is a place of considerable military strength, and the residence of a British military commandant and other dignitaries. Pop. in 1871, 107,149; (1881) 113,417.

S. was long thought to be one of the most ancient cities of Hindustan, but this opinion is now abandoned, and it is believed to have been a mere fishing-village as late as the 13th century. It first rose into importance as the spot whence the Mohammedans of Hindustan embarked on their religious voyage to Mecca. S. was sacked in 1512 by the Portuguese soon after their arrival in India. In 1612, an English force arrived here in two vessels, under the command of Captain Best, who defeated the Portuguese, and obtained a *firman* from the Mogul emperor, authorizing the residence of a British minister. The Dutch trade with S. commenced in 1616, when a Dutch factory was established. A French factory was founded in 1668. In the course of time, the English influence began to predominate. In 1759, the castle and fleet were made over to them; and from the year 1800 the government of the settlement has been entirely vested in their hands.

SU'RBASE. See PEDESTAL.

SURD. See IRRATIONAL NUMBERS.

SU'RETY. See GUARANTY.

SURFACE GRUB, the caterpillar of the *Great Yellow Underwing Moth* (*Triphæna pronuba*), a pretty large moth, with the upper wings deep brown or pale tawny, the under wings bright

orange with a black border. This moth abounds in hay-fields in Britain at the season of haymaking. The caterpillar, when full grown, is nearly an inch and a half long, pale green with a tinge

a, Surface Grub; *b*, Chrysalis; *c*, the Moth (*Triphæna pronuba*).

of brown, dotted with black, three pale lines down the back, and seven black spots on the inside of each of the two outer ones. It often does great mischief to the roots of cabbages and turnips, and also devours the roots of grass.

SURF DUCK, or SURF SCOTER (*Oidemia perspicillata*), a species of Scoter (q. v.) extremely plentiful on the coasts of Labrador, Hudson's Bay, and other very northern parts of America, from which great numbers migrate southwards in

Surf Duck (*Oidemia perspicillata*).

winter. It is a rare visitant of the coasts of Britain and other parts of Europe. In size, it is about equal to the Mallard. The plumage is black, except two patches of white on the head and back of the neck. It is never seen on lakes or rivers, but only on the sea-coast. It dives so quickly, that it is very difficult to shoot except when on the wing. Its flesh is rank, and has a fishy taste.

SU'RGEON, ARMY AND NAVY. In the army, surgeon is the grade in which an officer enters the medical department, and from which he is promoted in about 15 years to the rank of surgeon-major. He may be attached to a regiment, or serve with a district hospital; pay and duty being practically the same in either case. The pay rises gradually from £182, 10*s*. to £319, 7*s*. 6*d*. a year; and the surgeon ranks as a lieutenant for six years, and afterwards as a captain. In the medical department of the navy, surgeon is also the junior rank, reckoning for precedence as a sub-lieutenant for six years, and afterwards as a lieutenant. The pay varies from £200, 15*s*. a year to £310, 5*s*.

SURGEONS, COLLEGE OF. The present 'Royal College of Surgeons of England' dates its origin from the year 1460—1461, when Edward IV. 'did, at the supplication of the freemen of the mystery of barbers of the city of London using the mystery or faculty of Surgery, grant to them that the said mystery, and all the men of the same mystery of the said city, should be one body and perpetual community.' In 1500, four Masters in Surgery were appointed under the title of 'Magistri sive Gubernatores mistere Barbitonsorum et Sirurgicorum' (*sic*) and six years after this date the Barber-surgeons of Edinburgh were incorporated by a charter from James IV. Although the original charter granted to the Company of Barbers of London was confirmed by several succeeding kings, many persons practised surgery independently, and apparently in defiance of the Company; and in order to check unqualified persons, it was enacted in the 3d year of Henry VIII. (1511) 'that no person within the city of London, or within seven miles of the same, shall take upon him to exercise or occupy as a physician or surgeon, except he be first examined, approved, and admitted by the bishop of London, or by the dean of St. Paul's calling to him four doctors of physic, and for surgery other expert persons in that faculty.' Hence arose a company called the Surgeons of London. In the 32d year of Henry VIII. (1540), the Company of Barbers of London and the Company of Surgeons of London were united 'by the name of the Masters or Governors of the Mystery and Commonalty of the Barbers and Surgeons of London.'

It was not till the 18th year of George II. (1745) that the surgeons of London were by act of parliament separated from the barbers of London, and made a distinct corporation under the name of 'The Master, Governors, and Commonalty of the Art and Science of Surgery of London.' In the 40th year of George III. (1800), this company was dissolved, and replaced with their former and additional privileges by 'The Royal College of Surgeons of London.' A new charter was granted to the college in the 7th year of Victoria (1843), in which it was declared 'that it is expedient to create a new class of members, to be called Fellows,' and 'that from henceforth the corporate name or style of the said college shall be THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.' Power was given to the council to elect not less than 250, nor more than 300, members of the college to be Fellows.

These 'first Fellows' were mainly elected from the London and provincial hospital surgeons. Other Fellows might subsequently be elected from the members, 'after having complied with such rules and regulations as shall be considered expedient, and after having passed a special examination.' Those who are admitted to the fellowship by examination are distinguished in the college calendar by the letters *Ex.* being prefixed to their name. By an addition to the charter, obtained in 1852, power was given to the council, subject to certain regulations, to appoint members of 15 years' standing to the fellowship without examination. The college was likewise empowered to test the fitness of persons to practice midwifery and to grant certificates of such fitness; and in 1859 it was similarly authorized to test the fitness of persons to practise as dentists, and to grant certificates of such fitness.

The government of the college is vested in a Council of twenty four persons, including one president and two vice-presidents; and none but Fellows of 14 years' standing are eligible as members of council. Three members of council go out annually by rotation, and the vacancies are filled up on the first Thursday of July. There is a Board and a Court of Examiners, each consisting of ten members, including a chairman at the former, and a president at the latter; and as the examiners, who receive large emoluments (the fees to the Court of Examiners for the professional examination of members for the year ending June 24, 1878, were £10,110 15s.), are elected by the council, whose remuneration is slight, a position in the council is eagerly sought for as a stepping-stone to an examinership. Besides the Court of Examiners, there are special boards of examiners in Midwifery, in Dental Surgery, and in Classics, Mathematics, and French for the preliminary membership and fellowship examination. There are four professorships in connection with the college—viz., that of Human Anatomy and Surgery, the Hunterian Professorship of Comparative Anatomy and Physiology, the chair of Surgery and Pathology, and that of Dermatology. A Hunterian Orator is appointed every second year. The college sends a representative to the General Council of Education and Registration. A candidate for the membership of the college is required to pass a preliminary examination in the usual branches of a liberal education. The fee for the anatomical examination is £5, 5*s*., and that for the surgical, or pass-examination, is £16, 15*s*., making a total of £22. The fellowship fee is an additional 10 guineas. For details, see the *Calendar of the Royal College of Surgeons of England*.

The Museum of the College of Surgeons is incomparably the finest museum of its kind in the United Kingdom. The Hunterian Collection (see HUNTER, JOHN), which forms its basis, was purchased by a parliamentary vote of £15,000, and presented to the College in 1799. The edifice in Lincoln's Inn Fields (the germ of the present pile of buildings) was completed in 1813. The Hunterian Collection was estimated to consist of 13,682 specimens; the total number of specimens was recently reckoned at above 40,000. The library contains 36,000 volumes. Both the Museum and Library are readily accessible to visitors.

SURGEONS OF EDINBURGH, ROYAL COLLEGE OF, was originally an association of those professing 'surregerie and barbour-craft,' who obtained their first civic charter in 1504, and had it confirmed by James IV. next year. About 1589 began the custom of granting leave to barbers to practise their profession, without admitting them to the full freedom of the incorporation. For a century and a half the members of the craft were sole teachers and almost sole professors of the surgical art in Edinburgh, and contrived to hold their own against the physicians, who, both before and after their incorporation as a Royal College in 1681, made efforts to secure authority over the surgeons. In 1637 the surgeons granted the apothecaries a civil status in alliance with themselves; the nominal connection with the barbers was dissolved in 1732. A patent of 1694 settled the relations between the surgeons and the physicians, making amicable terms possible; and in 1778 the surgeons became formally a Royal College too.

Nevertheless they remained, much against their will, one of the incorporations of Edinburgh, till the act of 1851 dissolved what survived of their civic rights, and set the College free from the galling control of the Town Council. The College, which in 1881 had more than 450 fellows, sanctions the lectures of a staff of its own members as qualifying for examination candidates for its diploma of licentiate, and appoints a board of examiners. This examination is now usually taken in connection with that for the diploma of the College of Physicians.

SU'RGERY. There can be no rational doubt that surgery (Gr. *cheir*, the hand; *ergon*, work, signifying the manual interference, by means of instruments or otherwise, in cases of bodily injury, as distinguished from the practice of medicine, which denotes the treatment of internal diseases by means of drugs) is as old as man himself. Passing over the very little that is known regarding the state of surgery amongst the early Egyptians and the Jews, and the skill ascribed to Chiron and other mythical personages among the early Greeks, we may regard the true history of surgery as commencing with Hippocrates, who flourished in the 5th c. B.C. He was acquainted with the ordinary means of counter-irritation, as issues, a kind of moxa, and the actual cautery. He seems to have performed the capital operations with boldness and success; he reduced dislocations and set fractures, but clumsily and cruelly; extracted the fœtus with forceps when necessary, and both used and abused the trepan. He did not perform lithotomy, the practice of which seems at that time to have been well known, but to have been confined to a few, who made it their exclusive study. From the time of Hippocrates, we may pass over a couple of centuries, when, on the death of Alexander the Great, Alexandria became the great school of anatomy, surgery, and medicine. Herophilus and Erasistratus (300 B.C.) were as distinguished for their surgical skill as for their anatomical knowledge. One member of this school, Ammianus, invented an instrument by which he broke down stones in the bladder, thus anticipating by about 2000 years Civiale's discovery of lithotrity. When the great Alexandrian Library was destroyed by fire, Rome became the headquarters of science in all its departments. The early Romans of all ranks held surgeons and physicians in abhorrence, and trusted for cures, even in cases of dislocation and fracture, to spells and incantations. The first regular surgeon who settled in Rome was Archagathus (220 B.C.), a student of the Alexandrian School. At first, his skill procured for him a high reputation, but the old prejudices soon revived, and he was banished from the Roman capital.

The first Roman surgeon of real merit was Celsus, who flourished at the beginning of the Christian era, who improved the mode of performing lithotomy and amputation, described the operation for cataract, and first recommended the application of ligatures to wounded arteries, for the purpose of arresting hæmorrhage. His works contain an exact representation of surgical knowledge up to his own time. Aretæus of Cappadocia, who practised in Rome during the latter half of the 1st c., was the first to employ blisters, using cantharides (as we still do) for that purpose. Rufus of Ephesus, who lived half a century later, first tied an artery which had become aneurismal in consequence of being wounded in venesection. Galen, who practised in Rome in the latter part of the 2d c., mainly obtained his great reputation by his medical practice. His surgery was confined for the most part to fomentations, ointments, and plasters for external application; to the art of bandaging, and to the employment of complicated machinery in fractures and dislocations. There is little to record for several future centuries. Aëtius, in the 6th c., recommended scarification of the legs in dropsy, tried to dissolve urinary calculi by internal remedies, studied the diseases of the eye, and is the first writer who notices the guinea-worm. Paulus Ægineta, in the 7th c., opened internal abscesses by caustics, improved the operation of lithotomy, described several varieties of aneurism, extirpated the breast, performed laryngotomy and tracheotomy, and was the originator of the operation of embryotomy. His sixth book is regarded as the best body of surgical knowledge previous to the revival of letters. Rhazes, an Arabian, who had charge of a hospital at Bagdad, at the end of the 9th c., was the first to describe spina bifida, but he did not understand its real nature; he cauterized the bites of rabid animals, and gave a better account of hernia than any of his predecessors. To Avicenna, who lived a century later, we probably owe the first use of the flexible catheter, and of the instrument now generally known as Hey's saw. Albucasis (died 1122) describes an instrument for the cure of fistula lachrymalis, the removal of tumors by ligatures when the knife is inexpedient, the suture of wounded intestines, the use of the probang in obstruction of the gullet, &c., and is the only ancient writer on surgery who describes the instruments used in each special operation.

In 1271, Pitard, an eminent surgeon of his time, laid the foundation of the College of Surgeons of Paris. In our own country, Gilbertus Anglicanus, who lived about the beginning of the 14th c., is the first known surgical writer; he was shortly followed by John of Gaddesden, author of the *Rosa Anglica*. In the middle of that century, Guy de Chauliac, the first to describe the Cæsarian operation, practised at Avignon; and contemporary with him was John of Ardern, who is regarded as the first surgeon of his time. During the 15th c., the local application of arsenic for cancer was proposed by Taranta, a Portuguese surgeon practising at Montpellier; and lithotomy was removed from the hands of itinerant quacks into the department of pure surgery, by Colot, a surgeon to the French court. Moreover, the College of Surgeons dates from this century, having been founded in 1460—1461; while at the commencement of the next century (1505) the Edinburgh College was founded. The surgery of the 16th c. may be said to be represented by Ambrose Paré (q. v.). His works, first published in 1535, exerted a most beneficial influence on the profession. Towards the close of this century, Fabricius ab Acquapendente (q. v.), to whom we are indebted for the modern trephine, and for the use of the tube in tracheotomy, published his *Opera Chirurgica*, which passed through 17 editions. Early in the 17th c. (1612), a Scotchman named Lowe published *A Discourse on the whole Art of Chirurgery;* and about fifty years later, Wiseman, who has been appropriately termed 'the Paré of England,' and 'the true father of British surgery,' flourished. He was Serjeant-surgeon to Charles II.; and his surgical works, published in 1676, may still be read with interest. He was the first to dispel the dangerous belief, that gun-shot wounds were of a poisoned nature, and had consequently to be treated with the most painful kinds of dressing. Contemporary with him were James Young of Plymouth, who first performed the flap-operation in amputation; Scultetus (a German), the author of *Armamentarium Chirurgicum;* Frère St. Cosme, commonly known as Frère Jacques, a French monk, who considered himself specially commissioned by Heaven to cut for stone, and who has the merit of having converted the tearing into a cutting operation; Rau of Leyden, one of the most successful lithotomists of any age, and a pupil of Frère Jacques; and Roonhuysen, who divided the sternomastoid muscle for wry-neck, and may thus be regarded as the inventor of tenotomy.

The 18th c. produced, in England, White, the originator of excision of joints; Cheselden and Douglas, famous as lithotomists; Percival Pott, John Hunter, and Hey of Leeds; in Scotland, Monro, Benjamin Bell, and John Bell; in Ireland, O'Halloran and Dease; in France, Petit and Desault—the former celebrated for his work on Diseases of the Bones, and the latter distinguished for his improvements in surgical instruments of various kinds: in Germany, Richter and the illustrious Haller; and in Italy, Lancisi, Morgagni, and Scarpa. Moreover, in this century (1784) the Royal College of Surgeons in Ireland was founded. Never was surgery so brilliantly represented as during the present century. The London medical schools can point with equal pride to the names of Abernethy, Blizard, Brodie, Astley Cooper, Dalrymple (the oculist), Earle, Guthrie and Hennen (the great military surgeons', Aston Key, Liston, Stanley, Travers, Tyrrell (the oculist), Ware (the oculist), James Wilson, and many other nearly equally celebrated surgeons of an earlier date; and to the more recent ones of Arnott, Bowman, Erichsen, Fergusson, Prescott Hewett, Hilton, Lane, Lawrence, Luke, Paget, Spencer Wells, and a host of others. In Edinburgh were Sir Charles Bell, Lizars, Miller, Syme (whose name will ever be associated with a special amputation of the foot, and with the operation for stricture), and Simpson, discoverer of the application of chloroform to surgical practice. Amongst the most recent innovations and improvements in surgical practice may be mentioned the practice of *antiseptic surgery*, with which the name of Joseph Lister is so worthily associated. The principle of Professor Lister's method consists in the exclusion of septic matter—usually existing in the form of germs, and derived from the atmosphere—from raw or wounded surfaces. Wounds are dressed under *carbolic acid* spray, and with other preparations of this and other antiseptic substances, care being taken in dressing the wound to exclude ordinary atmospheric air. The results of this practice have been on the whole surprising; and recoveries from many serious operations have taken place in remarkably short periods, and with an absence of suppuration and other secondary effects of the inflammatory process.

Amongst the surgical celebrities of Dublin must be mentioned Peile, the inventor of Peile's lithotome and staff; Todd (the father of the late eminent Dr. Todd of London), who was the first to successfully revive the treatment of aneurism by compression; Colles, the first to describe the fracture known as Colles's fracture of the radius; Carmichael, distinguished for his opposition to the indiscriminate use of mercury in syphilis; Bellingham, and Hutton, whose names are associated with the full development of the revived treatment of aneurism by compression; Cusack, Porter, M'Dowel, and Sir Philip Crampton; Adams (well known for his treatise *On the Diseases of the Joints, and Chronic Rheumatism*), R. W. Smith (celebrated for his researches on fractures and

neuroma), and Jacob (the discoverer of the *Membrana Jacobi*). It would be impossible to mention a tithe of the names of those who have attained high surgical celebrity in the provinces during the present century. The Barons Dupuytren and Larrey, and MM. Amussat, Chassaignac, Civiale, Brasdor, Broca, Desmarre (the oculist), Nelaton, Roux, Sichel (the oculist), Velpeau, &c., have honorably sustained the reputation of French surgery. Beer (the oculist), Chelius, Dieffenbach, Von Gräfe (the oculist), Gurlt, Jäger (the oculist), Langenbeck, Stromeyer, and Wützer, constitute but a small portion of the eminent surgeons of Germany. Callisen of Copenhagen, Porta of Pavia, and Perogoff of St. Petersburg, may be taken as the surgical representatives of their respective countries. Amongst American surgeons the names of Valentine Mott, the Warrens, Marion Sims, and Gross deserve special notice. To understand what surgery now is, and to trace its recent progress, the reader should study the standard surgical treasures of Erichsen, Fergusson, Miller, and Syme; and the comprehensive and most valuable *System of Surgery*, edited by Mr. Holmes, and contributed to by many of the most eminent authorities on surgery. He will also do well to read Fergusson's *Lectures on Conservative Surgery*, and Syme's *Address on Surgery*, delivered before the members of the British Association in August 1865.

With the increase of knowledge, specialties naturally develop themselves; and such has been the case in surgery. The diseases of the eye, the diseases of the ear, the diseases peculiar to women, the diseases of children, and deformities (the treatment of which is termed Orthorpædic Surgery), more or less separate themselves, at least in large towns, from general surgery, and constitute special departments, of which dentistry may be considered one; as most of the eminent dentists of the present day are regularly educated and qualified surgeons.

It is deserving of record that within recent years, nearly all the British universities have commenced to give Surgical as well as Medical Degrees.

For further information, see the histories of surgery by Le Clerc (1696), Freind (Lond. 1725), and Moir; those (German) by Sprengel, Bernstein, Gründer, and Häser (1865); the 'Historical Notice' in Miller's *Principles of Surgery;* and *The International Encyclopædia of Surgery*, edited by Professor Ashurst, of Pennsylvania University, and containing contributions by distinguished European surgeons (vol. i. 1881).

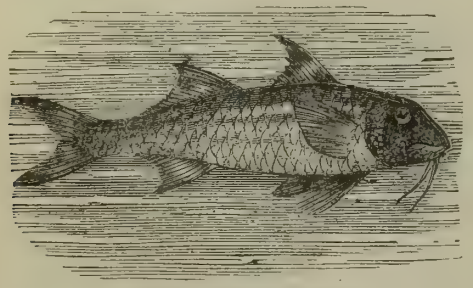
SURINA'M. See GUIANA, DUTCH.

SURINAM BARK. See ANDIRA.

SURMOU'NTED, in Heraldry, a term used to indicate that one charge is to be placed over another of different color or metal, as

in the annexed figures, which may respectively be blazoned: Sable, a pile argent surmounted by a chevron gules; and, Argent, a cross gules surmounted by another ore.

SURMU'LLET (*Mullus*), a genus of acanthopterous fishes of the family *Mullidæ*, a small family formerly included in *Percidæ*, but distinguished by having two dorsal fins widely separated from one another, the first spinous; and large, easily detached, strongly ciliated scales on the head and body. The genus *Mullus* has no teeth on the upper jaw, but a disc of pavement-like teeth on the



Surmullet (*Mullus surmuletus*).

front of the vomer. Two long barbels hang from the under jaw, or, when not in use, are folded up against it. Only two species are known, both abundant in the Mediterranean, and both found on the British coasts. They very generally receive the name MULLET, by which they are counfounded with a very different genus. The STRIPED S., or STRIPED RED MULLET (*M. surmuletus*), is sometimes very plentiful on the southern coasts of England, but is rarer towards the north. It approaches the shores in summer, and many surmullets are then taken in mackerel nets; but at other seasons it is only obtained from comparatively deep water by trawl-nets. It sometimes attains, in the Mediterranean, a weight of six or seven pounds, but has never been known much to exceed three pounds in the British seas, and is seldom more than two pounds in weight. The ancient Romans, who held it in the highest esteem, gave prodigious prices for fish of unusually large size. They kept surmullets in their *vivaria;* but there the fish did not increase in size. The color is pale pink, with three or four yellow longitudinal stripes; but where any of the scales have been rubbed off, beautiful tints of purple and bright red appear, which takes place also during the struggles of the fish when dying, and the Romans were therefore accustomed to bring surmullets alive into their banqueting-rooms, that the guests might see them die, and enjoy the brilliant display of color, before eating the fish. The liver was regarded as peculiarly delicious, and was bruised in wine to make a *garum* for the flesh. The S. is still regarded as one of the best of fishes.—The RED S., or PLAIN RED MULLET (*M. barbatus*), is very rare on the coasts of Britain. It is a much smaller fish than that already described. Other species of *Mullidæ* are found in tropical seas.

SU'RNAME (either from its being an additional name—Fr. *surnom*, Ital. *sopranome*—or from the practice of writing it over the Christian name, which is to be seen in the court rolls and other ancient munuments), in modern Europe, the family name. The Roman *cognomen* partook somewhat of the same character; but the introduction of the surnames of modern time cannot be traced further back than the latter part of the 10th century. See NAME.

SU'RPLICE (Lat. *super pellicium*, above the robe of fur), a linen or muslin vestment, worn by clerks of all degrees of orders in the discharge of their public religious offices. It is by some supposed to be derived from the longer and more flowing vestment which, in the Roman Catholic Church, is still used in the mass, and is called the 'alb;' but in that church the suplice is worn not alone by priests, but by all who have been admitted even to the church tonsure. Its most ordinary use is for the service of the choir, and it is also employed, along with the stole, by priests in the administration of the sacraments, and in preaching. The use of the surplice was strongly objected to by the Calvinistic and Zwinglian reformers on the continent, and by the Puritans in England, who regarded this vestment as a relic of popery, and made it the subject of vehement denunciations. The argument against it is to be found in Beza, *Tractat. Theolog.* iii. 29, and its defence in Hooker's *Ecclesiastical Polity*, book v., ch. 29. Ere ritualism became so common in England, no little stir used from time to time to be created by the use of the surplice by the preacher in the pulpit, contrary to the more general practice in the Anglican church. Preaching in the surplice has been associated in the popular mind with a Romanizing tendency, although it is difficult to say on what basis this association rests.

SU'RREY (Sax. *Suth-rice*, the south kingdom), an inland county in the south of England, bounded on the north by Middlesex, and on the east by Kent. Area, 483,178 acres; pop. (1871) 1,091,635; (1881) 1,435,842. S. is traversed from west to east by a well-marked ridge of the North Downs, which rises in Botley Hill, above Titsey, to the height of 880 feet. On the north side of this range, the land slopes gradually to the banks of the Thames, which runs along the northern border; but on the south side the descent is rugged and broken, affording pleasing and sometimes romantic scenery. South of the main range, and about four miles south of Dorking, is Leith Hill, 993 feet high, the most important elevation in this quarter of the country. Stretching along the southern bank of the Thames, and extending over a space about six miles in breadth, is a tract which belongs to the London clay formation; further south, and likewise extending from west to east, there is a tract of plastic clay, varying in breadth from one to five miles. Chalk, weald clay, and iron-sand formations occupy the south of the county. The principal streams are the Mole and Wey, tributaries of the Thames. The soil of the northern half of the county is fertile; in the west and south-west, the land is, to a great extent, covered with heath. The climate is soft and mild in low-lying districts, and is favorable to the production of corn and grass. More than four-fifths of the entire area are under culture. In the north, in the vicinity of London, there are numerous market-gardens, the produce of which is sent to supply the markets of the metropolis. Hops, wheat, and the ordinary crops are raised. The county contains much wood, and the beauty of the scenery, and the facility of communication with London, have attracted many residents to S., which is consequently studded over with mansions and villas. Manufactures are carried on in Southwark and in the other southern suburbs of London, as well as in Croydon, Guildford, Kingston, and Reigate, which are the principal towns. The county returns four members to the House of Commons.

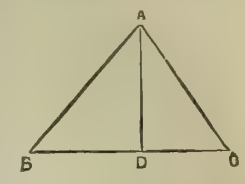
SU'RTURBRAND, a kind of Brown Coal (q. v.) found in the north of Iceland, and there used for fuel. It has a great resem-

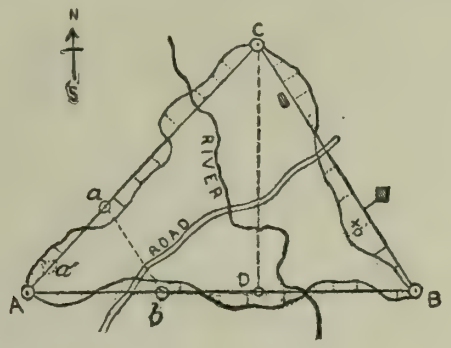
blance to the black oak found in bogs. It is capable of being made into tables and other articles of furniture, but is too brittle to be cut into shavings by a plane.

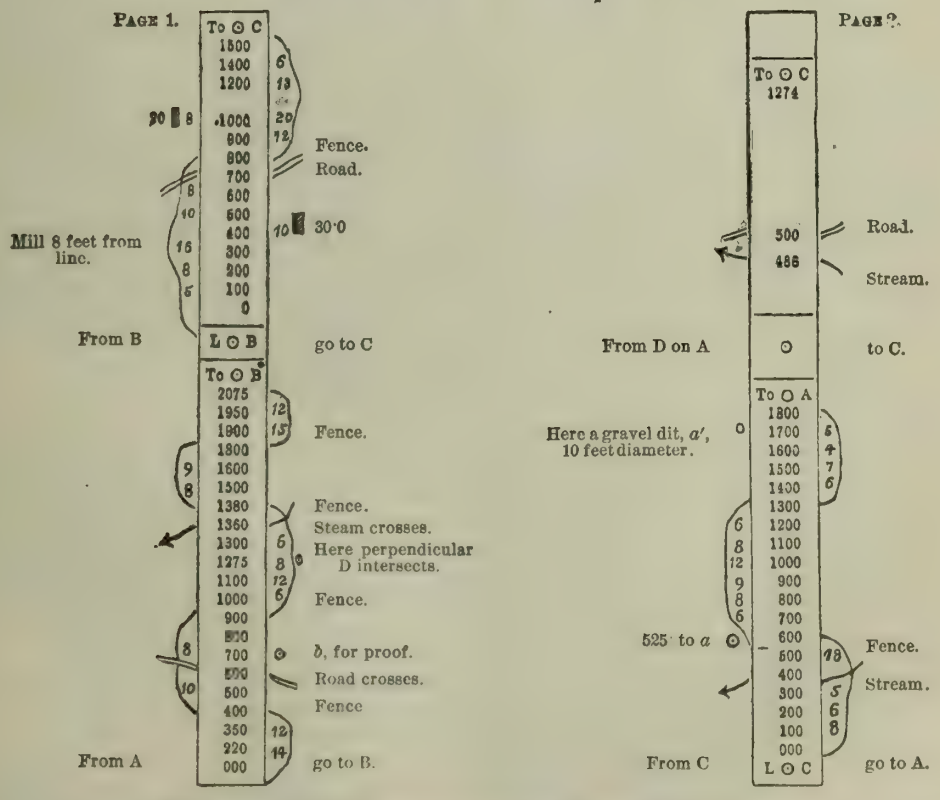
SURVEY'ING. Land surveying may be considered the earliest practicable application of the art of geometry or earth measurement, and must have been in some more or less rude form coeval with agriculture and the division or appropriation of the soil. In Rome, surveying was considered one of the liberal arts, and the measurement of lands was intrusted to public officers who enjoyed certain privileges; and it is probable that the system of measurement practised by them was very similar to our plain surveying with the chain and cross staff of the present day, and has been handed down to us through the feudal period. An examination of ancient records and title-deeds will show that both areas and boundary-lines of the different enclosures forming fields, hundreds, townlands, &c., are often laid down with a considerable degree of accuracy.

Land surveying may be considered under the following heads: (*a.*) Plain surveying with the chain, and without the aid of angular instruments, except the cross staff or fixed angle of 90°. (*b.*) Modern engineering surveying, in which angular instruments are used. (*c.*) Coast and military surveying. (*d.*) Trigonometrical surveying (q. v.).

triangle, ABC, are supposed to be accessible, and are carefully measured on the ground, and then laid down or platted to scale on paper, when an accurate figure of the triangle will be obtained, on which the length of the sides can be marked. To get the area, however, it will be necessary to determine the length of the perpendicular line AD, and this is usually done (when possible) on the ground by means of a simple instrument called a cross, which consists of two sights or fine grooves at right angles to each other, and being placed on the line BC (keeping B and C visible in one of the sights), nearly opposite the angle A, is moved gradually till the angle A is intersected by the other sight. The line AD can be also laid down on the drawing, and its length found by scale, and afterwards verified on the ground, or it may be at once laid down on the ground by the use of the chain alone. An improved reflecting instrument, called an optical square, is also often used for this purpose. Any boundaries along the lines or sides of the triangle, ABC, can be determined by the use of Offsets (q. v.) or insets as they occur on right and left of line. No matter what the form of the surface to be surveyed may be—polygon, trapezium, or trapezoid—it may thus be determined by a judicious subdivision into triangles; and when the survey is







The line *ab* may be similarly booked and platted, and any lines intersecting shown.

The fundamental rule of every description of land surveying, from the humble attempt of the village schoolmaster to lay down an irregular garden plot, to the trigonometrical survey of a large extent of the earth's surface, when the aid of the most refined improvements of modern science is indispensable, is simply to determine three elements of a triangle, and thence to calculate its area.

In plain surveying with the chain, the three sides of the triangle are measured, and the angles are not taken. This is not of a very extended nature or character, and when no serious obstructions exist, chain surveying is both accurate and expeditious, especially if proof or tie lines are properly introduced, for the purpose of testing the accuracy of the work.

In every description of surveying, it is best to make the original triangle as large as possible, and to work from a whole downwards, rather than build up a large triangle by the addition of several small ones. It would be impossible here to lay down

rules to meet the many difficulties which arise in the practice of surveying, and indeed the best test of a good surveyor is the ease with which he will overcome local obstructions, which appear almost insurmountable to a novice, or even to a theoretical surveyor with little field practice.

Where buildings or other impediments are found in the measurement of a straight line, they are generally passed by the erection of short perpendiculars sufficient to clear the obstacles, and a line parallel to the original measured as far as they exist, when the original line can be again resumed. Differences of level, occurring in measuring a line where no instruments are used, are generally compensated or allowed for by the judgment of the surveyor.

In registering the dimensions taken on the ground, such as sides of triangles, offsets, intersections of roads, fences, &c., and everything necessary to make a perfect delineation or plan of the surface, surveyors use what is called a field-book, the mode of keeping which varies very much with individual practice. Some surveyors use hand sketches or rough outlines of the form of the ground, and mark the dimensions on them, while others use the ordinary form of field-book, or a combination of the two methods, which perhaps is the best when any difficult complications happen on the ground, such as the frequent occurrence of buildings, enclosures, water, &c., along the line.

In the ordinary field-book, the center column, commencing from the bottom, represents the length of any line or side of a triangle; and the figures in the column, the distance at which the offsets to the right or left are taken, or where roads, streams, fences, &c. cross the line, or buildings adjoin the same. We give on page 189 the field-book of the assumed survey of the triangle ABC, with the different offsets and insets on its sides, and where roads, fences, streams, &c. cross them, the detail of which can be obtained by subdividing the triangle into smaller internal ones. The figure can thus be laid down from the book, and its area calculated by the formula $\frac{AB \times CD}{2}$ and the offsets and insets calculated, added, or deducted, by the methods given in OFFSETS.

Ponds, plantations, and enclosures of different kinds may be surveyed with a chain, especially if their form be such that they can be conveniently included in the area of a triangle, the correctness of which, being proved by proper tie-lines, the form, area, &c. may be ascertained by offsets, or rather insets from the sides.

SURYA is, in Hindu Mythology, the god of the sun. His wife is, in later mythology, *Sûryâ*, who, in order to escape his embraces, transformed herself into a mare, but nevertheless became the mother by him of the twin *As'wins*, afterwards the heavenly physicians. Besides Sûryâ, he had several other wives, by one of whom, *Sanjnâ*, he begot Yama, the god of death, and the river Yamunâ, or Jumna. By Kuntî, before her marriage with Pân'd'u (q. v.) he had *Karn'a*, who, therefore, was an elder brother of the Pân'd'u princes, but in the conflict between the Pân'd'us and the Kurus, sided with the latter, and was killed by Arjuna. S. became also, by his other progeny, the ancestor of a royal dynasty, called after him, *Sûryavans'a*, or the solar race. S. is represented with a lotus-flower in his hand, on a chariot drawn by seven horses, and conducted by his charioteer Arun'a, the god of the dawn, who is represented without legs.

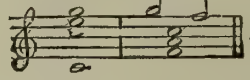
SU'SA (Shushan in Daniel, Esther, &c., derived by some from Shoshan, a lily), probably the modern Sus or Shusn, in lat. 32° 10′ N., and long. 48° 26′ E., situated between the Chapses or Eulæus (Ulai in Daniel), and the Shapur, anciently the capital of Susiana (the *Elam* of Scripture, mod, *Khusistan*), and one of the most important cities of the old world. Its foundation is variously ascribed by ancient writers to Darius Hystaspes, or to Memnon, the son of Tithonus; and its name, together with its ground-plan, is traced on Assyrian monuments at the time of Assur Bani Pal, about 660 B.C. At the time of Daniel's vision 'at Shushan in the palace,' it was under Babylonian dominion, but came, at the time of Cyrus, under Persian rule; and the Achæmenian kings raised it to the dignity of a metropolis of the whole Persian Empire, and as such Æschylus, Herodotus, Ctesias, Strabo, &c. speak of it. At the Macedonian conquest it was still at its height, and Alexander is reported to have found in it vast treasures, together with the regalia. On Babylon becoming the principal city of Alexander and his successors, S. gradually declined, but seems still to have contained enormous wealth at the time of its conquest by Antigonus (315 B.C.). It was once more attacked by Molo in his rebellion against Antiochus the Great; and during the Arabian conquest of Persia it held out bravely for a long time, defended by Hormuzan. The ruins of its ancient buildings, the palace described in Esther among them, cover a space of about three miles. The principal existing remains consist of four spacious artificial platforms above 100 feet high. Traces of a gigantic colonnade were laid bare by Mr. Loftus, with a frontage of 343 feet, and a depth of 244. Cuneiform inscriptions exist, together with many other relics similar to those found at Persepolis (see PERSEPOLIS; compare also CUNEIFORM). The 'tomb of Daniel' shown near S. is a modern Mohammedan building.

SU'SA, a city of Northern Italy, province of Turin, stands on the right bank of the Dora Riparia, at the foot of the Cottian Alps, 32 miles west of Turin. It is an episcopal see, and has a cathedral consecrated in 1028, with a baptistery of one single block of green marble. Among its other notable buildings are the episcopal palace, the town-hall, and the Borgo de' Nobili. The surrounding country produces wines, fruits, mulberry trees, and wood. The road over Mont Cenis, opened in 1810, begins at Susa. Pop. 3300.

S., called by the Romans *Segusio*, is a very ancient city; it was founded by the Celts, and was in the reign of Augustus the capital of the Celtic chief Cottius, from whom the Cottian Alps received their name, and during the empire was the starting-point for crossing Mont Cenis. A triumphal arch, erected by Cottius in honor of Augustus, still remains.

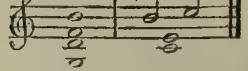
SUSA'NNAH, HISTORY OF, *The Judgment of Daniel*, also *Susannah and the Elders*, are the different titles of a well-known story, which forms one of three apocryphal additions to the Book of Daniel; the other two being *The Song of the Three Holy Children*, and *The History of Bel and the Dragon* (q. v.). It relates how S., the wife of Joiachim, and daughter of Hilkiah, celebrated alike for her beauty and her virtue, was falsely accused of adultery by certain 'lovers' whose advances she had spurned; and how, being condemned to death on their evidence, she was saved by the wise Daniel, who tore the mask from her enemies, and caused them to experience the fate they had designed for her. The question—not a very important one certainly—has been much debated, both in the early and later times of the church, whether or not the story of S. is true; and arguments (of various weight) have been adduced to show that the book is a fabrication, a fable, a legend, and a history. The most probable view, perhaps, is that which regards it as a tradition of something that did happen in the life of Daniel, but which has been moulded into a moral fiction by the hand of a literary artist. The original is believed to have been Greek and not Hebrew. In most MSS. it precedes the first chapter of the Book of Daniel, and so we find it in the old Latin and Arabic versions; but the LXX., the Vulgate, the Complutensian Polyglot, and the Hexaplar Syriac, place it at the end of the present book, and reckon it as the 13th chapter.

SUSPE'NSION, in Music. A note is said to be suspended when it is continued from one chord to another to which it does not properly belong, and to a proper interval of which it must eventually give way. Thus we have here the note G extended from the first chord into the second, in which it is first suspended, and then resolved into the chord FACF:



. This example is a suspension from above,

in which a descent is necessary for its resolution: but a note may also be suspended from below, when it is resolved by an ascent:



SUSPENSION AND INTERDICT, in Scotch Law, is a process by which the suspender, who initiates the proceeding, seeks to stop or to interdict some act, or to prevent some encroachment on property or possession, or in general to stay any unlawful proceeding. The first step is to present a note of suspension and interdict to the Lord Ordinary, who grants *interim* interdict either with or without caution, and orders the note to be answered, or refuses interdict. When the note is answered, the Lord Ordinary passes or refuses the note, and continues or recalls the interdict as the case may be.

SUSPENSION BRIDGES. In these bridges, the roadway is suspended from chains passing over piers or towers, and firmly fixed at their extremities. Fig. 1 is a sketch of an ordinary sus-

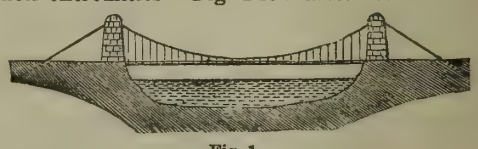


Fig. 1.

pension bridge. When the roadway is equally loaded over its length, the curve of the chain is a parabola. The weight of the roadway being known, the strain upon the chain, and its requisite strength, are readily determined. For example, in Fig. 2, if A be the center of the bridge, and it be required to find the strain upon

the chain at the point B, it is evident that the weight of the roadway between A and B is supported by the chain at B; we have

Fig. 2.

then to find what strain in the direction of the length of the chain will support this vertical load. By the principles of mechanics, if we draw a right-angled triangle BCD, of which the side BC is a tangent to the curve at B, CD is vertical, and BD horizontal; and if the length of CD represent numerically the load on AB, then BC will represent numerically the strain on the chain produced by that load, and BD will be what is called the horizontal component of this strain. This horizontal part of the strain is the same for every part of the curve; it is the total strain on the chain at the center A, and the strain carried over the towers and balanced by the backstays, which are firmly anchored to the ground behind them. In this manner the conditions of strength and stability of a bridge uniformly loaded are easily determined, but when we have a rolling load which is heavy in proportion to the weight of the bridge, as for example a railway train, the case is very different, for when the train only occupies one half of the bridge, the chain will be depressed towards that side, and raised at the center; thus an undulation will be produced in the bridge, which, if the train be moving rapidly, would endanger its stability. Various combinations have been devised to overcome this difficulty.

The most simple, and practically the best, is to stiffen the roadway so that the strain of the passing load is distributed over a considerable length of the chain. In this manner, large railway bridges have been constructed in America; among them is that over the Niagara above the Falls, of which the span is 822 feet, and the height of the platform above the river 250 feet. The great Brooklyn and New York bridge, opened in 1883, is 3500 feet long, has a span of 1600 feet, and is 135 feet above the water. An ordinary suspension bridge is liable to both vertical and horizontal oscillations, the former taking place when a train or other load is passing over it, and the latter being due to the action of the wind. These oscillations cannot be altogether prevented, but can be so reduced as to be harmless, by the use of stays, stretching both from the towers and from points on shore to various parts of the bridge. Suspension bridges are generally used in positions where the span is great, and the rolling loads neither great in proportion to the weight of the bridge itself, nor very rapid in their motion. Many beautiful examples are to be seen in this country; among others, we may instance the Menai Bridge, 580 feet span, and the Clifton Bridge, near Bristol, 703 feet span.

SUSPENSION OF ARMS. See TRUCE.

SUSQUEHA'NNA, an American river, which has its origin in Otsego and Canandaigua Lakes, in western New York, and flowing eastward, receives the rivers Unadilla and Chenango, then, turning south, enters Pennsylvania, where it receives the Pittston, the Tioga, the West Branch, and the Juniata, and empties itself into the Chesapeake Bay, at Havre de Grace, Maryland, 400 miles from its source, and 153 from its junction with the West Branch. It is a shallow, rapid, mountain river, with varied and romantic scenery. A canal follows its course, and great quantities of timber are floated down in the spring freshets. Near the mouth, it is famous for waterfowl, especially the Canvasback Duck, and has important fisheries.

SUS'RUTA is one of the great medical authorities of ancient India. See *Medicine*, under SANSCRIT LITERATURE. His work is called *Ayurveda*, and consists of six books. It was edited by S'rî Madhusûdana Gupta, in 2 vols. (Calcutta, 1835—1836).

SU''SSEX (South-Saxons), a maritime county in the south of England, bounded on the N. by Surrey and Kent, and on the W. by Hampshire. Area, 936,911 acres; pop. in 1871, 417,456, and in 1881, 490,316. The South Downs (see DOWNS) traverse the county from west to east, ending about 20 miles east of Brighton, in the lofty cliff of Beachy Head. The northern escarpment of the Downs is precipitous, but leads down to the fertile and richly wooded district of the Weald (see DOWNS). A remarkably productive tract, from two to seven miles in breadth, extends west from Brighton along the coast to the Hampshire border; and in the south-east of the county the rich marsh lands that line the coast, and which are 30,000 acres in extent, make excellent pasture-grounds. Of the Down-land there are about 50,000 acres, covered with a fine, short, and delicate turf, on which the well-known breed of Southdown sheep, to the number of 300,000, are pastured. Of the Weald district, which formerly was covered with dense forests, there are within the county 425,000 acres; a considerable tract has been brought under cultivation. Irrespective of the less productive districts, there are in the county 120,000 acres of rich arable land; 150,000 acres are occupied by woods, which abound chiefly in the Weald, and in the Forest Ridge in the north-east of S., where are St. Leonard's Forest (10,000 acres), and Ashdown Forest (18,000 acres). The chief rivers are the Arun, Adur, and Ouse, which have their origin in the north of the county, and flow south into the Channel. In the south of S. the climate is mild, and several large towns (see BRIGHTON and HASTINGS) are largely resorted to by those who seek health or relaxation. Seaford and Pevensey Bays are much frequented by vessels, and the east portion of the coast is defended by martello towers. The county has for centuries been divided into the six rapes of Lewes, Pevensey, Hastings, Chichester, Arundel, and Bramber. It returns four members to parl. Capital, Chichester.

SUSTENTA'TION FUND, a fund provided in the Free Church of Scotland for the support of the ministers of the church. The idea of such a fund was probably derived by Dr. Chalmers from the system of the Wesleyan Methodists, and a scheme devised by him was made public before the Disruption, so that arrangements had been made, and a small sum already collected, when that event took place. The scheme was afterwards carried into operation throughout the whole of Scotland, and continues unmodified to the present time. The members of the church are called upon to contribute, according to their own will and ability, to a common fund; of which, after payment of expenses, payments to a fund for widows and orphans, pensions to retired ministers, &c., an equal division is made among the ministers of the church, with a few exceptions, chiefly in the case of newly formed congregations. The amount of the fund has gradually increased from £68,-704 in 1843—1844, to £172,408 in 1880, when 796 out of 1097 ministers received an equal dividend of £160, the surplus being divided among the ministers (780) of those charges whose contributions amounted to a certain average sum per member. Congregations are permitted to supplement the stipends of their own ministers, and if able are expected to do so. The supplement in some congregations in towns much exceeds the dividend from the fund; but in many parts of the country, the whole, or almost the whole stipends of the ministers are derived from it. The question had been much discussed, whether an equal dividend ought to be made, or a proportion established between the liberality of a congregation and the amount paid to its minister. The subject of the Sustentation Fund is of interest, not only to the Free Church of Scotland, but to all unendowed churches.

SU'THERLAND, a county in the extreme north of Scotland, is bounded on the E. by Caithness and the North Sea, on the N. and W. by the Atlantic, and on the S. by Ross and Cromarty. Area, 1,207,188 acres; pop. in 1871, 24,317, and in 1881, 23,366. The coast-line is 60 miles in extent; and the shores, rugged on the north and west, where they are broken by the force of the Atlantic, are comparatively flat on the east. The southern and central regions of S. are the most elevated; and rivers, mostly from the middle of the county, flow east and south-east to the North Sea, and north, north-west, and west to the Atlantic. The principal mountain peaks are Ben More in Assynt (3273 feet), and Ben Clibrigg (3158 feet). The chief rivers are the Oikel and the Shin—which, with other affluents, unite to form Dornoch Firth—the Brora, Helmsdale Water, and Naver. Extensive moors, the haunt of herds of red deer, stretch across the county; and the rivers and lakes, the chief of which is Loch Shin (q. v.), form numerous low-lying valleys or straths. In the interior and western districts, the climate is cold, and the county is often deluged with continuous rains; but in the eastern districts the climate is mild, and the soil very fertile in all agricultural produce. In 1880, there were 30,151 acres under crops, of which 10,309 acres were under corn, 5639 acres green crops, 6517 clover and other artificial grasses, and 7451 acres permanent pasture. The number of cattle in the same year was 12,595; sheep, 235,497; and swine, 1165. Coal, granites of various colors, marble, limestone, &c. are found. In Nov. 1868, traces of gold were found in a burn in S. A number of 'diggers' were attracted to the district, but the gold found, though of excellent quality, was hardly sufficient to repay their labor. The Highland Railway passes through the county. Manufactures are inconsiderable. There are good salmon, herring, and white fishings. S. is well supplied with churches. The schools are well attended, and Gaelic is rapidly giving way to English. Almost the whole of the county belongs to the Duke of Sutherland. The present duke is eminent for the zeal with which he has devoted himself to the improvement of S., spending large sums in the reclamation of land by steam-ploughs, the construction of railways, &c.

S. received its name from the Northmen, who frequently descended upon and pillaged it prior to the 12th c., and called it the Southern Land, as being the limit on the south of their settlements. The condition of the people of S. before 1811, in which year the county began to be opened up by roads, was miserable. Their sustenance dependent mostly upon their half-starved flocks, was very precarious, and would have failed them often had not

charity administered relief. A former Duke of Sutherland effected what are known as the 'Sutherland Clearances,' by compelling such of his tenants as could not support themselves, owing to the unsuitability to agricultural purposes of the districts upon which they dwelt, either to remove to more fertile districts, where they received land at a merely nominal rent, or to emigrate at his expense to Canada.

SU''TLEJ, or SUTLUJ, an important river in the north-west of India, the eastmost of the five rivers of the Punjab, rises in the sacred lakes of Manasarovara and Rawan-Hrad in Thibet, lat. 30° 45′ N., long. 81° 15′ E. At its outfall from Lake Manasarovara, at between 19,000 and 20,000 feet above sea-level, it is a rapid torrent 30 feet broad. It flows northwest for 150 miles, when turning to the south-west it receives the Spiti or Li, a larger stream than itself. The Spiti is 8592 feet above sea-level, when it joins the S., and the scene of the confluence of the two rivers is sublime in the highest degree. Continuing a south-west course, the S. breaks through the mountain-rampart of the Himalaya, and after flowing in all about 850 miles, in the course of which it is joined by the Beas and the Chenab, it falls into the Indus in lat. about 29° N. Its upper course is supposed to be identical with the Hesudrus, and its lower course (in which it is called the Ghara) with the Hyphasis of the ancients.

SU''TLER is a vendor of provisions allowed by the Quartermaster-general to follow an army in the field, for the purpose of supplying the soldiers with such luxuries as they can afford to purchase. Sutlers are under martial law, accompany the baggage on a march, and are narrowly watched, and severely punished if found guilty of any irregularities towards either the soldiers or inhabitants of the country. In the French army a soldier in each regiment is licensed to act as sutler, and is called *vivandier*. See also CANTEEN.

SUTRA (from the Sanscrit *siv*, to sew, literally, therefore, a thread or string) is, in Sanscrit literature, the technical term of aphoristic rules, and of works consisting of such rules. The importance of the term will be understood from the fact, that the *groundworks* of the whole ritual, grammatical, metrical, and philosophical literature of India are written in such aphorisms, which therefore constitute one of the peculiarities of Hindu authorship. The object of the Sûtras is extreme brevity; and, especially in the oldest works of this class, this brevity is carried to such an excess, that even the most experienced would find it extremely difficult, and sometimes impossible to understand these aphorisms without the aid of commentaries, which, however, are fortunately never wanting, wherever a work is written in this style. Though there is no positive evidence as to the cause or causes which gave rise to this peculiarity of Hindu composition, the method of teaching in ancient India—an account of which is afforded in some of the oldest works—renders it highly probable that these Sûtras were intended as memorial sentences which the pupil had to learn by heart, in order better to retain the fuller oral explanation which his teacher appended to them. But it is likewise probable that this method of instruction itself originated in the scarcity or awkwardness of the writing material used, and in the necessity, therfore, of economizing this material as much as possible; for that writing was known and practised at the remotest period of Hindu antiquity, is now placed beyond a doubt, though a startling theory was propounded, some years ago, to the effect that writing was unknown in India, even at the time of the great grammarian Pân'ini. The manner, however, in which, up to this day, the Hindus are in the habit of keeping the leaves of their books together, seems to throw some light on the name given to this aphoristic literature.

The leaves—generally narrow, and even at the present time often being dried palm leaves, on which the words are either written with ink or scratched with a style—are piled up, and, according to the length of the leaves, pierced in one or two places, when, through the hole or holes, one or two long *strings* are passed to keep them together. The name of Sûtra was probably, therefore, applied to works, not because they represent a thread or string of rules, but on account of the manner in which these works were rendered fit for practical use; just as in German a volume is called *Band*, from its being 'bound.' That a habit deeply rooted outlives necessity, is probably also shown by these Sûtra works; for while the oldest works of this class may be called Sûtras by necessity, there are others which convey the suspicion that they merely imitated the Sûtra style after the necessity had passed away, more especially as they do not adhere to the original brevity of the oldest Sûtras; and the Sûtras of the Buddhists (see PIT'AKA), conspicuous for their prolixity, could scarcely lay claim to the term, if compared with the Sûtra of the Brahmanical literature.

SUTTEE' (an English corruption from the Sanscrit *satî*, a virtuous wife) means the practice which prevailed in India, of a wife burning herself on the funeral pile, either with the body of her husband, or separately, if he died at a distance.

The practice of suttee is based by the orthodox Hindus on the injunctions of their S'âstras, or sacred books, and there can be no doubt that various passages in their Purân'as (q. v.) and codes of law *countenance* the belief which they entertain of its meritoriousness and efficacy. Thus, the *Brahma-Purân'a* says: 'No other way is known for a virituous woman after the death of her husband the separate cremation of her husband would be lost (to all religious intents). If her lord die in another country, let the faithful wife place his sandals on her breast, and, pure, enter the fire. The faithful widow is pronounced no suicide by the recited text of the R'igveda.' Or the code of *Vyâsa*: 'Learn the power of that widow who, learning that her husband has deceased, and been burned in another region, speedily casts herself into the fire,' &c. Or the code of *Angiras*: 'That woman who, on the death of her husband, ascends the same burning pile with him, is exalted to heaven, as equal in virtue to Arundhatî (the wife of Vasisht'ha). She who follows her husband (to another world) shall dwell in a region of joy for so many years as there are hairs on the human body, or 35 millions. As a serpent-catcher forcibly draws a snake from his hole, thus drawing her lord (from a region of torment), she enjoys delight together with him. The woman who follows her husband to the pile expiates the sins of three generations on the paternal and maternal side of that family to which she was given as a virgin. . . . . No other effectual duty is known for virtuous women, at any time after the death of their lords except casting themselves into the same fire. As long as a woman (in her successive transmigrations) shall decline burning herself, like a faithful wife, on the same fire with her deceased lord, so long shall she be not exempted from springing again to life in the body of some female animal. When their lords have departed at the fated time of attaining heaven, no other way but entering the same fire is known for women whose virtuous conduct and whose thoughts have been devoted to their husbands, and who fear the dangers of separation.' See for other quotations, H. T. Colebrooke, *Digest of Hindu Law*, vol. ii. p. 451, ff. (Lond. 1801); and his 'Essay on the Duties of a Faithful Hindu Widow,' reprinted from the *Asiatic Researches*, in his *Miscellaneous Essays*, vol. i. (Lond. 1837). But however emphatically these and similar passages recommend a wife to burn herself together with her deceased husband, it should, in the first place, be observed that *Manu*, who, among legislators of ancient India, occupies the foremost rank, contains no words which enjoin, or even would seem to countenance, this cruel practice; and, secondly, that no injunction of any religious work is admitted by the orthodox Hindus as authoritative, unless it can show that it is taken from, or based on, the revealed books, the Vedas (see S'RUTI). An attempt has of late years been made by Râjâ Râdhakânt Deb, to show that, in a text belonging to a particular school of the Black Yajurveda (see VEDA), there is really a passage which would justify the practice of suttee; but in the controversy which ensued on this subject between him and the late Professor H. H. Wilson, it clearly transpired that the text cited by the learned Râjâ is of anything but indubitable canonicity; moreover, that there is a verse in the R'igveda which if, properly read, would enjoin a widow not to burn herself, but, after having attended the funeral ceremonies of her husband, to return to her home, and to fulfil her domestic duties; and it seems, at the same time, that merely from a misreading of a single word of this verse from the R'igveda, that interpretation arose which ultimately led to a belief and an injunction so disastrous in their results. See H. H. Wilson, 'On the Supposed Vaidik Authority for the Burning of Hindu Widows, and on the Funeral Ceremonies of the Hindus,' reprinted from the *Journal of the Royal Asiatic Society*, vol. xvi., in his Works, vol. ii., edited by Dr. Rost (Lond. 1862). That an immense number of widows have fallen victims to this erroneous interpretation of the oldest Vedic text, is but too true.

Some fifty years ago, however, the East India Company took energetic measures to suppress a practice which it was perfectly justified in looking upon as revolting to all human feelings, and which it would have likewise been entitled to consider as contrary to the spirit of the Vedic religion. This practise may now be said to have been successfully stopped; for though, from habit and superstition, even now-a-days cases of suttee occur, they are extremely rare; and all reports agree that the enlightened natives everywhere, except, perhaps, in certain native states, support the action of government to repress this evil of bygone times.

SU''TURE (Lat. *sutura*, a seam) is a term employed both in Anatomy and Surgery. In Anatomy, it is used to designate the modes of connection between the various bones of the cranium and face. A suture is said to be *serrated*, when it is formed by the union of two edges of bone with projections and indentations (like the edge of a saw) fitting into one another. The coronal, sagittal, and lambdoidal sutures (see SKULL) are of this kind. A suture is termed *squamous*, when it is formed by the overlapping of the bevelled (or scale-like) edges of two contiguous bones. There are

also the *harmonia* and the *schindylesis* sutures, the former being the simple apposition of rough bony surfaces, and the latter being the reception of one bone into a fissure of another.

In surgery, the word suture is employed to designate various modes of sewing up wounds, so as to maintain the opposed surfaces in contact. As it may fall to the lot of any person, on an emergency, to have to sew up a wound, the following general rules, applicable to all forms of suture, should be attended to. In passing the needle, the edges of the wound should be held in contact with the fore-finger and thumb of the left hand; and the needle should penetrate the surface at about an angle of 50° (rather more than half a right angle), and should, at least, pass through the whole thickness of the skin at each stitch. The distance from the edge of the wound at which each stitch should enter and leave the skin, must vary with the depth of the wound; but there should never be less than the eighth of an inch between the margin of the wound and the entrance or exit of the needle. Sutures should not include vessels, nerves, muscles, or tendons. The line of the thread should cross that of the wound at right angles. For incised wounds on the surface of the body, when the edges can only be transfixed from the cutaneous surface, or when the opposite margins can both be traversed by one plunge, a curved needle (such as a common packing-needle) is most convenient, whereas a strong straight needle is more convenient for the completely free margins of extensive wounds, such as are left after amputation. Fig. 1 represents various forms of needles used by surgeons; fig. 2 shows the *twisted suture*, as used in the operation

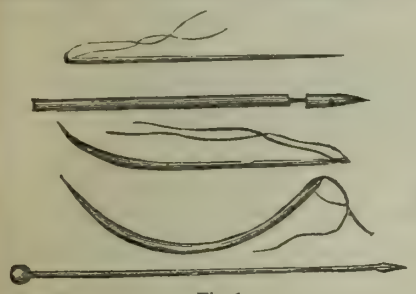

Fig. 1.

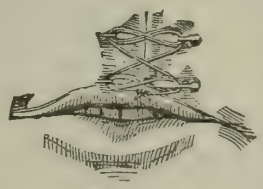

Fig. 2.

for hare-lip, in which the wound is transfixed by pins, around which, beginning with the uppermost, a thread is twisted, in the form of the figure 8.

SUVOROF, Alexander Vassilivitsh, Count, Prince Italiński, a Russian field-marshal, and the most famous of Russian generals, was descended from a family of Swedish origin, and was born in Finland, November 13 (O. S.), 1729. His father, who was an officer of the Russian army, and rose, in after-times, to the rank of general and senator, enrolled young S., at the age of 13, in the Semenof regiment, where he remained till 1754, when he was promoted to the grade of lieutenant. S. was present in the Russian army engaged in the Seven Years' War (q. v.), and for distinguished behavior at Kunersdorf, received the grade of colonel. By a constant succession of eminent services in the Polish civil war (1768), in the war against the Turks (1773—1774), in suppressing internal disturbances, and in subduing the Tartars of the Kuban (1783), he continued to grow in reputation, and rose to the rank of general. In the Turkish war (1787—1792) he was commander-in-chief, for the first time brought the bayonet prominently into use in the Russian army, and decided by it the bloody battle of Kinburn (1787), which would otherwise have been a total rout. At the siege of Otchakof (1788), where he narrowly escaped being made prisoner, the battle of Fokshany (August 1, 1789), which he gained in conjunction with the Austrians, and the decisive victory of Rymnik (September 22, 1789), his headlong bravery, and peculiar system of rapid and repeated attack by overwhelming numbers, secured him complete success. For this last victory, which saved the Austrians under Coburg from annihilation or capture, S. was created, by the Emperor Joseph II., a count of the empire, and from his own sovereign received the title of Count *Suvorof-Rymnikski*. His last great achievement, and the one which has given a predominant coloring to S.'s reputation in Western Europe, was the capture of Ismail (q. v.).

S.'s report of his success was couched in the following terms, 'Glory to God and Your Excellency; the town is taken; I am in it.' He was then appointed (1791) governor of the newly conquered provinces; was afterwards sent (1794) to complete the annihilation of the Polish monarchy, which he effected by repeated victories over the Polish armies, the capture of Praga by storm, and the *repossession* of Warsaw (November 19), where a horrible massacre of the inhabitants took place. The grade of field-marshal, and presents of rare value, rewarded these successes. Under Paul, he fell into disgrace (1798), from his impatience of the emperor's fantastic military regulations, and was deprived of his rank; but being restored through English influence, he commanded the Russian auxiliary army sent to co-operate with the Austrians in Italy. In April 1799, he reached Verona; compelled Moreau to retire behind the Adda with immense loss, including more than 8000 prisoners; entered Milan in triumph (April 29); again defeated the French under Macdonald, after a desperate three days' conflict, at the Trebbia (June 17—19), and a third time at Novi (August 15), depriving them of the whole of Northern Italy. His campaign in Switzerland, which promised to bring him face to face with Massena, then the best general in Europe, was rendered abortive by the tardiness of the Austrians, and the Russians, in spite of S.'s remonstrances, were soon after recalled. His escape from the Schackenthal, where he was hemmed in by the French, is considered by many to be the most brilliant and daring retreat ever executed. While on his return to St. Petersburg, where a brilliant reception was awaiting him, he fell dangerously ill in Lithuania, and though, on his recovery, he found himself a second time in disgrace, he continued his route, and arrived privately in the capital, where he died sixteen days afterwards, May 17, 1800. His remains were honored by a magnificent funeral, and the czar Alexander erected a statue to his memory on the Champ-de-Mars.

This most extraordinary man had naturally a weak constitution, but rendered it almost invulnerable by exercise, strict temperance, and the regular use of cold baths. His mode of life was of Spartan simplicity, and though the oddity of many of his habits seemed only calculated to encourage ridicule, they, in combination with his paternal care of his men, gave him a powerful hold on the affections of an army at once so ignorant and so thoroughly national in sentiment as the Russian. S. was inflexible in his resolutions and promises, and of incorruptible fidelity. His skill as a general has often been doubted, on the strength of his favorite remark, that all military tactics could be expressed in three words, *stoupai i bi*, 'forward and strike;' but his career shows him to have been possessed of all needful military knowledge—though he hated idle manœuvring—and to have excelled in promptitude and ingenuity of conception, and boldness and rapidity of execution.

SU'ZERAIN (Fr. from Lat. *supremus*), a feudal lord. According to the feudal system, as developed in Northern Europe, every owner of Allodial (q. v.) lands was compelled to acknowledge himself the vassal of a suzerain, and do homage to him for his lands. The term was applied less to the king than to his vassals, who had sub-vassals holding of them.

SVENIGORO'DKA, a town of Russia, in the government of Kiev, 150 miles south from Kiev, on an affluent of the Southern Bug. Pop. (1880) 11,375.

SWALE. See Yorkshire.

SWALLOW (*Hirundo*), a Linnæan genus of birds of the order *Insessores*, and tribe *Fissirostres*, now divided into a number of genera, which form the family *Hirundinidæ*. This family consists of birds which prey on insects, catching them in the air, and have

Swallows:
1, Common or Chimney Swallow (*Hirundo rustica*); 2, Sand Martin (*H. riparia*); 3, House Martin (*H. urbica*).

great powers of flight, now soaring to a great height, now skimming near the surface of the ground or of the water, and wheeling with great rapidity. The bill is short and weak, very broad at the base, so that the gape is wide; the wings are very long, pointed, and more or less sickle-shaped when expanded; the legs are short and weak, and in some—the Swifts (q. v.)—more so than those of any other birds. The tail is generally forked. The plumage is close and glossy. The species are very numerous, and widely diffused, being found in almost all countries. Such of them as occur in the colder parts of the world are summer birds of passage, migrating to warmer regions when winter approaches and insects disappear. The family is divided into two groups,

Swifts, which have remarkably long and curved wings, very small weak legs and short toes, the hinder toe generally directed forwards, and *Swallows*—some of which are also called *Martins*—having wings not quite so long nor so much curved, rather stronger legs, and longer toes, three before and one behind. The COMMON S., or CHIMNEY S. (*Hirundo rustica*), exhibits a character common to many other species, in the very long and deeply-forked tail, the two lateral feathers of which far exceed the others in length. The plumage is very beautiful, the upper parts and a band across the breast glossy bluish black, the forehead and throat chestnut, the lower parts white, and a patch of white on the inner web of each of the tail-feathers except the two middle ones.

The whole length of the bird is about 8½ inches, of which the outer tail-feathers make 5 inches. The nest is made of mud or clay, formed into little pellets and stuck together, along with straw and bents, and lined with feathers. It is open and cup-shaped, and is generally placed in a situation where it is sheltered from wind and rain, as a few feet down an unused chimney, under the roof of an open shed, or in any unoccupied building to which access can be obtained. Two broods are produced in a year. The migration of this and other British species of S., now recognized by all naturalists as an unquestionable fact, was formerly the subject of much dispute, and swallows were supposed by many to become torpid in winter, although it was difficult to imagine that if so they should not frequently be found in that state. The geographical range of this species extends over great part of Europe, Asia, and Africa.—The WINDOW S., or HOUSE-MARTIN (*H. urbica*, or *Chelidon urbica*), is another very common British species, glossy black above, white below, and on the rump; the feet covered with short downy white feathers, which is not the case in the Chimney S.; the tail long, but its outer feathers not remarkably so. The nest is built of mud or clay, like that of the Chimney S., but is hemispherical, with the entrance on the side, and is attached to a rock, or, very frequently, to the wall of a house, under the eaves or in the upper angle of a window, to the annoyance of housekeepers who prefer the cleanness of their windows to the lively twitter of the birds, and the opportunity of watching their process of nest-building and their care of their young. House-martins congregate in great numbers, as chimney swallows also do before their autumnal migration, and disappear all at once. The house-martin is among the birds of Lapland and Iceland. The only other common British species of S. is the SAND-MARTIN (*H. riparia*), smaller than either of the preceding, the toes naked, the tail moderately forked, the plumage brown on the upper parts and across the breast, the under parts white. It makes its nest in sandy river-banks, the sides of sand-pits and other such situations, excavating a gallery of 18 inches or two feet, sometimes 3, or even 5 feet in length, and more or less tortuous, in the extremity of which some soft material is placed for the reception of the eggs. This wonderful excavation is accomplished entirely by the bill of the bird. The floor slopes a little upwards from the entrance, so that the lodgement of rain is prevented.

The sand-martin is more local than the other British swallows; but it is distributed over most parts of Europe, Asia, Africa, and North America.—The PURPLE S., or PURPLE MARTIN (*H. purpurea*), is a North American species, which has in a few instances been known to visit the British islands. The general color, both of the upper and under parts, is shining purplish blue; the wings and tail black. It abounds in North America, and is a universal favorite in the northern parts, being hailed as the harbinger of spring, and frequenting even the streets of towns. It is a very general practice to place boxes near houses for the martins to make their nests in, which are very inartificial, consisting merely of dried grass, leaves, moss, feathers, and the like. Boxes nailed to trees are also readily occupied by the RUFOUS-BELLIED S. (*H. erythrogaster*), another North American species. But this species, which very nearly resembles the Chimney S. of Britain, makes a nest of mud and fine hay, in the form of the half of an inverted cone, with an extension at the top, for one of the parent birds to sit in occasionally. The REPUBLICAN S., or CLIFF S. (*H. fulva*), of North America, makes a nest of mud, in form somewhat like a Florence flask, which it attaches to a rock or to the wall of a house. Hundreds sometimes build their nests in close proximity. The FAIRY MARTIN (*H. Ariel*), a small Australian species, also builds a flask-shaped nest, with the mouth below, attaching it to a rock, or to the wall of a house, and numerous nests are often built close together.—Some of the swallows of tropical countries are much smaller than any of the European species.—The East Indian swallows, which make the Edible Nests (q. v.), belong to the section of the family to which the name Swift is given.

SWALLOWING, THE ACT OF, is accomplished by a set of associated movements which have been divided by physiologists into three stages. In the first stage, the food having been previously duly reduced to a pulp by trituration and insalivation, is carried back by the contraction of various muscles until it has passed the anterior palatine arch. See PALATE. So far, the movements are purely voluntary. The second stage now commences, during which the entrance of food into the nasal cavities and larynx is most carefully guarded against by certain reflex (involuntary) actions, which have been only clearly recognized since the introduction of the use of the laryngoscope during the last few years. The tongue is carried further backwards, the larynx rises so as to be covered by the epiglottis, which is depressed, and lies horizontally, so that its upper border touches the posterior wall of the pharynx. Coincident with these movements, the sides of the posterior palatine arch contract by muscular action, and approach each other like a pair of curtains, so as almost to close the passages from the fauces into the posterior nostrils; the closure being completed by the uvula. A sort of inclined plane is thus formed, and the morsel slips downwards and backwards into the pharynx, which is raised to receive it. Very little, if any, voluntary action is here exerted. The third stage—the propulsion of the food down the œsophagus—then commences; and this process is effected in the upper part by means of the constrictor muscles of the pharynx, and in the lower, by the muscular coat of the œsophagus itself. At the point where the latter enters the stomach, there is a sort of sphincter muscle, which is usually closed, but which opens when sufficient pressure is made on it by accumulated food, closing again when this has passed. See Carpenter's *Principles of Human Physiology*.

SWALLOW-WORT. See ASCLEPIAS.

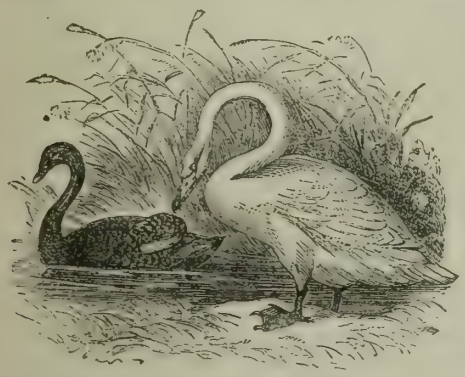
SWAMMERDAM, JAN, a distinguished naturalist, was born at Amsterdam, 12th February 1637. S., almost from his boyhood, showed the greatest eagerness in the study of natural history. Having entered upon the study of medicine, he particularly occupied himself with anatomy, and continued unremittingly to collect insects, to investigate their metamorphoses and habits, and, by the aid of the microscope, to examine their anatomic structure. He took his degree of Doctor of Physic at Leyden, in 1667, and entered upon the practice of his profession, which his bad health, however, soon compelled him to relinquish. He continued to be chiefly engrossed with anatomy and entomology. His treatise on Bees appeared in 1673; a treatise on Ephemera in 1675. It is impossible, however, for us to enumerate his many publications, all of which were first published in Dutch, and afterwards translated into Latin, and many of them into English, French and German. S.'s discoveries were very numerous, both in human and comparative anatomy. His skill in using the microscope was very great, and his manipulation of the most minute subjects extremely dexterous. He succeeded in giving distinctness to the forms of very minute viscera, by inflating them with air; a method of his own invention. It is melancholy to add, that S., who had always displayed strong religious feelings, and expressed them in his writings, was at last carried away by the fanatical extravagances of Antoinette Bourignon (q. v.), began to think all his former pursuits sinful, and relinquished them for a visionary religious life of mere meditation and devotion. His health rapidly declined, and he died at Amsterdam, 17th February, 1680. No man of his time contributed more than S. to the progress of natural history and physiology. He was the inventor of the method of making anatomical preparations by injecting the blood-vessels with wax, and also of the method of making dry preparations of the hollow organs, now generally employed.

SWAN (*Cygnus*), a genus of birds of the Duck (q. v.) family (*Anatidæ*), constituting a very distinct section of the family. They have a bill about as long as the head, of equal breadth throughout, higher than wide at the base, with a soft cere, the nostrils placed about the middle; the neck very long, arched, and with 23 vertebræ; the front toes fully webbed, the hind toe without membrane; the keel of the breast-bone very large; the intestines very long, and with very long cæca. They feed chiefly on vegetable substances, as the seeds and roots of aquatic plants, but also on fish-spawn, of which they are great destroyers. They are the largest of the *Anatidæ*. They have a hissing note like geese, which they emit when offended, and strike with their wings in attack or defence. The common notion, that a stroke of a swan's wing is sufficient to break a man's leg, is exaggerated. The COMMON S., MUTE S., or TAME S. (*C. olor*), is about 5 feet in entire length, and weighs about 30 lbs. It is known to live for at least 50 years. The male is larger than the female. The adults of both sexes are pure white, with a reddish bill; the young (cygnets) have a dark bluish gray plumage, and lead-colored bill. The bill is surmounted by a black knob at the base of the upper mandible, and has a black nail at its tip. In its wild state, this species is found in the eastern parts of Europe and in Asia; in a half-domesticated state it has long been a common ornament of ponds, lakes, and rivers in all parts of Europe. It is an extremely beautiful bird, when seen swimming, with wings partially elevated, as if to catch the wind, and finely curving neck.

The ancients called the S. the Bird of Apollo or of Orpheus, and ascribed to it remarkable musical powers, which it was sup-

posed to exercise particularly when its death approached. It has, in reality, a soft low voice, plaintive and with little variety, which is to be heard chiefly when it is moving about with its young. The nest of the S. is a large mass of reeds and rushes, near the edge of the water, an islet being generally preferred. From 5 to 7 large eggs are laid, of a dull greenish-white color. The female S. sometimes swims about with the unfledged young on her back; and the young continue with their parents till the next spring. The S. is now seldom used in Britain as an article of food, but in former times it was served up at every great feast, and old books are very particular in directions how to roast it and to prepare proper gravy.—The POLISH S. (*C. immutabilis*), of which flocks have occasionally been seen in Britain in winter, differs from the Common S. in its orange-colored bill, in the smaller tubercle at its base, and in the shape and position of the nostrils. The young are also white, like the adults. It belongs chiefly to the north-eastern parts of Europe. Many naturalists regard it as the true wild state of the Common Swan.

The WHISTLING S., ELK S., or HOOPER (*C. ferus*), abounds



Wild Swan, or Hooper (*Cygnus ferus*), and Black Swan (*C. atratus*).

in the northern parts of Europe and Asia. Flocks frequently visit Britain in severe winters, and their migrations extend as far south as Barbary. A few breed in the Orkney Islands, but the greater number in more northern regions. The size is about equal to that of the Common S., and the color is similar, but the bill is more slender, is destitute of knob, and is black at the tip, and yellow at the base. This bird is frequently brought to the London market. The names Hooper and Whistling S. are derived from the voice. The anatomical differences between this species and the Common S. are more considerable than the external, particularly in the double keel of the breast-bone forming a cavity which receives a long curvature of the windpipe.—BEWICK'S S. (*C. Bewickii*), another native of northern Europe, is more rare in Britain, but flocks are sometimes seen. It is about one-third smaller than the Whistling Swan.—The AMERICAN S. (*C. Americanus*) nearly resembles Bewick's Swan. It breeds in the northern parts of North America, and its winter migrations extend only to North Carolina.—The TRUMPETER S. (*C. buccinator*) is another American species, breeding chiefly within the Arctic Circle, but of which large flocks may be seen in winter as far south as Texas. It is rather smaller than the Common Swan.

The ancients spoke of a black S. proverbially as a thing of which the existence was not to be supposed, but Australia produces a BLACK S. (*C. atratus*), rather smaller than the Common S., the plumage deep black, except the primaries of the wings, which are white. The bill is blood-red. It has been introduced into Britain, and breeds freely. It is very abundant in some parts of Australia.—The BLACK-NECKED S. (*C. nigricollis*) is a South American species, as is the DUCK-BILLED S. (*C. anatoides*), the smallest of all the species, white, with black-tipped primaries, common about the Strait of Magellan. It is a curious circumstance that the black color appears more or less in all the species of the southern hemisphere, and in them alone, except in the approach to it made in cygnets.

Swans, according to the law of England, are birds-royal. When they are found in a partially wild state, on the sea and navigable rivers, they are presumed to belong to the crown, and this is one of the prerogatives of the crown, though it may be delegated to a subject. The royal birds generally have a mark on them, and the king's swan-herd once was an important person. A subject is not entitled to have a swan-mark unless he has a qualification of land, and has a grant from the crown, or prescriptive use. But any person may have swans in his grounds in a tame state, and then he has a property in them. Whoever steals or destroys swans' eggs, forfeits 5*s.* for every egg, and whoever steals a marked swan of the crown, or a tame swan, commits felony. In Scotland, there is some trace of the bird having been once treated with royal honors.

SWAN RIVER, a river of Western Australia (q. v.).

SWA'NSEA (Welsh, *Abertawy*) a market-town, municipal and parliamentary borough and seaport of the county of Glamorgan, South Wales, stands on the right bank and at the mouth of the Tawe, 60 miles west-north-west of Bristol. The harbor is formed by means of piers of masonry, projecting from either side of the mouth of the Tawe into Swansea Bay, a wide inlet of the Bristol Channel. The vast resources of the coal-field in the midst of which the town is situated, began to be explored and turned to commercial account about the year 1830; and since that time the progress of S. has been so rapid, that it is now the most important town in South Wales. The houses and public edifices and institutions are of recent erection. A good public hall was erected in 1864, and a spacious and well-arranged infirmary in 1867. Smelting and refining copper is the staple trade of the town, and the chief source of its prosperity. The coal obtained in the vicinity is peculiarly adapted for smelting purposes, and great quantities of ore are brought hither to be smelted, not only from the copper-mines of Britain, but from Cuba and the west coast of South America. In the immediate vicinity of the town, there are smelting works, in which about 185,800 tons of copper, copper ores, silver ores, and zinc ores (equal in value to about £4,000,000) are smelted annually. Of the whole amount of copper manufactured in Great Britain, seven-eighths are smelted at S. and in its immediate vicinity. In 1859, a large floating dock of 13 acres was opened. Its north side is lined with warehouses. In 1881 a new dock was finished at a cost of £300,000. An excellent system of water-works was completed in 1868 at a cost of upwards of £70,000. Patent fuel, composed of a mixture of culm and tar, and compressed into the shape of bricks, is an important article of manufacture and trade. There are extensive potteries, and tin, silver, and china works, breweries, rope-walks, and tanneries.

In 1880, 2345 vessels, of 523,381 tons, entered the port, and 2973, of 696,679 tons, cleared. There are abundant means of communication landward by canals and railways. Pop. (1851) of municipal and parliamentary limits, 31,461; (1861) 41,606; (1871) of mun. bor., 51,702; (1881) mun. bor., 63,739. Of the old castle of S., the ruined remains are used as a military store. S. unites with Aberavon, Kenfigg, Loughor, and Neath in sending a member to the House of Commons.

SWARGA is the paradise of the Hindu god Indra (q. v.). It is the residence of some of the inferior gods and deified mortals, who there rest in the shade of the five wonderful trees—*Mandâra*, *Pârijâta*, *Santâna*, *Kalpavr'iksha*, and *Harichandana;* drink *Amr'ita*, or the beverage of immortality; and enjoy the music of the *Gandharvas*, and the dancing of the heavenly nymphs, the *Apsarasas*.

SWARMING, a peculiar mode of reproduction which has been observed in some of the *Confervaceæ*, *Desmideæ*, &c. The granules which form the green matter in the plant, or in one of its joints, become detached from each other, and move about in the cell with great rapidity. The external membrane swells in one point, and finally bursts there, when the granules escape into the surrounding water to become new plants. At first, they issue in great numbers, but those which remain last, move about within their cell for a long time before they find the way out. Their motion is supposed to be due to cilia. After escaping they continue their movements for some time, and most of them finally become grouped together in little masses on some substance, before beginning to vegetate.

SWATOW, or CHAU-CHOU, a seaport town on the coast of China, in the province of Quang-tung, 212 miles east-north-east from Canton. It is one of the ports which were opened to foreign trade by the treaty of Tien-tsin, and has a resident British consul. The trade is upon the whole increasing. In 1877, the imports were valued at £1,787,000, and the exports at £367,400. Half the total is direct trade with foreign ports. Opium is the chief article of importation, next to which rank cotton and woollen goods, metals, and cotton-yarn. The chief exports are sugar, rice, tea, and paper. S. is pleasantly situated on a sheltered bay.

SWE'ABORG, or SVE'ABORG, a great Russian fortress in Finland, sometimes called 'the Gibraltar of the North,' protects the harbor and town of Helsingfors, from which it is 2 miles distant. The fortifications extend over seven islands, the *Nylandischen Skären*, but the grand central point is the island of Wargöe. The islands are connected with each other by means of bridges, and between two of them lies the single narrow entrance to the harbor, which can hold from 70 to 80 ships of the line. S. has a civic population of about 3000, the greater part of whom are manual laborers, ship-carpenters, and traders, and a garrison of some 5000 men (including women and children). During the Crimean war, the Anglo-French fleet in the Baltic made a reconnaissance of the place, and bombarded it for two days (9th and 10th August 1855), but found the defences too formidable to be reduced by the means at their disposal.

SWEARING, PROFANE, according to the law of England, is an offence for which the party may be convicted by a justice of the peace according to a scale of penalties. A day laborer, a common soldier, sailor, or seaman forfeits 1*s.* per oath; every other person under the degree of a gentleman, 2*s.*; and every person above the degree of a gentleman, 5*s.*—for a second offence, double these sums; for a third, treble, &c. If the cursing take place in presence of a justice of the peace, the latter may convict the swearer then and there, without further proces or evidence; and in all cases a constable may apprehend a profane swearer; and carry him before a justice. On a recent occasion, a man swore a volley of oaths, twenty times repeating the oath, and the justices fined him 2*s.* for each repetition, making in all £2, and this was held a proper conviction. The justices of the peace in Scotland have a similar jurisdiction intrusted to them, to convict of profane swearing, and fine according to the rank of the party.

SWEAT (A.-S. *swat*, Sansc. *svaidas*, Lat. *sudor;* Gr. *hydor*, moisture; Lat *ud(us)* = wet), or Perspiration. The nature, composition, and uses of this fluid in the normal state have been sufficiently noticed in the article SKIN. It may be additionally remarked, in connection with the physiology of sweat, that the composition of this fluid varies materially according to the part of the body from which it is secreted. Thus Funk found the sweat of the feet was richer in fixed salts than that of the arm, in the ratio of 5 to 3; and Schotten found a considerable preponderance of potassium in the former. In the negro, Dr. Copland and other observers have found that both the gaseous exhalations from the skin, and the solid matters contained in the sweat, were much greater than in the white races. It has been shown in the article SKIN that the sweat-glands, like the lungs and kidneys, act as depurating organs, and separate and carry off effete matters from the blood.

This eliminating action of the skin is modified in various diseases; in some cases being diminished, as in the early stage of fevers, in inflammations before suppuration commences, in scurvy, diabetes, sun-stroke, &c., while it is more or less increased in the sweating stage of ague, in acute rheumatism, in Asiatic cholera, in certain adynamic fevers, in the advanced stages of pulmonary consumption, in the formation of matter in internal parts, &c. The sweat is naturally acid in health, but in prolonged sweating the secretion becomes neutral, and finally alkaline. Little is known with certainty regarding the coloring matters of sweat. In cases of jaundice, the sweat sometimes communicates a yellow tinge to the body-linen; and instances of blue, red, and bloody sweat are on record. Cases of sweat of these colors are recorded in Simon's *Animal Chemistry* (Syd. Soc. Trans.), (Lond. 1845), vol. ii., p. 110. Cases of unilateral sweating, stopping abruptly at the middle line, have been occasionally noticed, especially in aneurism of the aorta.—See Gairdner's *Clinical Medicine*, page 557. Dr. Druitt has pointed out the use of hot water as a remedy for profuse perspiration. He has found it serviceable in (1) oversweating in good health and hot weather; (2) undue sweating in special parts of the body, as the hands, feet, or armpits; (3) true hectic; and (4) ordinary night sweats in phthisis not preceded by hectic symptoms. To be of any service, the water must be applied at as great a heat as the patient can possibly bear (see his paper on this subject in the *Medical Times* for March 4, 1865). For a very interesting and learned discussion on our Saviour's bloody sweat during his Passion, the reader may consult Stroud *On the Physical Cause of the Death of Christ*, and Trusen's chapter *Von dem Blutschweisse Christi* in his *Darstellung der Biblischen Krankheiten*, 1843.

SWEATING SICKNESS, THE, is the term given to an extremely fatal epidemical disorder, which ravaged Europe, and especially England, in the 15th and 16th centuries. It derives its name 'because it did most stand in sweating from the beginning vntil the endyng,' and 'because it first beganne in Englande, it was named in other countries the Englishe sweat.'—*The Boke of Jhon Caius against the Sweatyng Sicknes*. It first appeared in August 1485 in the army of Henry VII., shortly after his arrival at Milfort in South Wales from France, and in a few weeks it spread to the metropolis. It was a violent inflammatory fever, which, after a short rigor, prostrated the powers as with a blow; and amidst painful oppression at the stomach, headache, and lethargic stupor, suffused the whole body with a fœtid perspiration. All this took place in the course of a few hours, and the crisis was always over within the space of a day and night. The internal heat which the patient suffered was intolerable, yet every refrigerant was certain death. '*Scarce one amongst a hundred* that sickened did escape with life.'—Holinshed, vol. iii., p. 482. Two lord mayors of London and six aldermen died within one week; and the disease for the most part seized as its victims robust and vigorous men. It lasted in London from the 21st (some authorities say the middle) of September to the end of October, during which short period 'many thousands' died from it. The physicians could do little or nothing to combat the disease, which at length was swept away from England by (as many supposed) a violent tempest on New-Year's Day. The disease did not reappear till the summer of 1506, when it broke out in London, but does not seem to have occasioned any great mortality. In July 1517, it again broke out in London in a most virulent form; it being so rapid in its course that it carried off those who were attacked in two or three hours. Amongst the lower classes, the deaths were innumerable, and the ranks of the higher classes were thinned.

In many towns a third, or even a half of the inhabitants were swept away. On this occasion, the epidemic lasted about six months. In May 1528—the year in which the French army before Naples was destroyed by pestilence, and in which the putrid fever known as *Trousse-galant* decimated the youth in France—the sweating sickness again broke out in the metropolis, spread rapidly over the whole kingdom, 'and fourteen months later, brought a scene of horror upon all the nations of Northern Europe, scarcely equalled in any other epidemic.'—Hecker's *Epidemics of the Middle Ages* (Syd. Soc. Trans.), p. 238. How many lives were lost in this epidemic, which has been called by some historians *the great mortality*, is unknown; but the mere fact that the king (Henry VIII., who, whatever his faults, was never accused of cowardice) left London, and endeavored to avoid the disease by continually traveling, shows the general feeling of alarm that existed. In the following summer (July 25, 1529), having apparently died out in England, it appeared in Germany, first at Hamburg, where it is recorded that 8000 persons died of it, and shortly after at Lubeck, Stettin, Augsburg, Cologne, Strasburg, Hanover, &c. In September, it broke out in the Netherlands, Denmark, Sweden, and Norway, whence it penetrated into Lithuania, Poland, and Livonia. By January of the following year, after an existence of three months, it had entirely disappeared from all these countries. For three-and-twenty years the sweating sickness totally disappeared, when for the last time (April 15, 1551) it burst forth in Shrewsbury. The banks of the Severn seemed to be the focus of the malady, which was carried from place to place by poisonous clouds of mist. There died within a few days 960 of the inhabitants of Shrewsbury, the greater part of them robust men and heads of families. The disease spread rapidly over the whole of England, but seems to have disappeared by the end of September. The deaths were so numerous, that one historian (Stow) states that the disorder caused a *depopulation* of the kingdom. The very remarkable observation was made in this year, that the sweating sickness uniformly spared foreigners in England, and on the other hand, followed the English into foreign countries.

The immoderate use of beer amongst the English was considered by many as the principal reason why the sweating sickness was confined to them. 'By the autumn of 1551,' says Hecker, 'the sweating sickness had vanished from the earth; it has never since appeared as it did then and at earlier periods; and it is not to be supposed that it will ever again break forth as a great epidemic in the same form, and limited to a four-and-twenty hours' course; for it is manifest that the mode of living of the people had a great share in its origin, and this will never again be the same as in those days.'—*Epidemics of the Middle Ages* (Syd. Soc. Trans.), p. 306.

SWE'DEN (*Sverige*), the eastern portion of the Scandinavian peninsula, constitutes with Norway (q. v.) one joint kingdom. It is situated in 55° 20′—69° 3′ N. lat., and 11°—24° E. long., and is bounded on the N. and W. by Norway; on the extreme S.W. and S. by the Cattegat, which separates it from Denmark; on the S.E. and E., as far as 66° N. lat., by the Baltic and the Gulf of Bothnia; and from thence to the extreme N. by Russia. The area is nerly 170,000 sq. m.; and the pop. was, in 1871, 4,204,177. Its length is 969 miles, and its greatest width from 150 to 280 miles. S. is divided into three provinces—viz., Norrland, the largest and most northern; Sweden Proper, or *Svea-rike* (land of the Swedes), in the center; and Götland or *Göta-rike* (land of the Goths), to the south.

Unlike Norway, S. possesses few high mountains, but contains numerous lakes of large dimensions. The coast skirting the Baltic, and the adjoining islands, are for the most part low and sandy, although in some parts, as in the vicinity of the outlet of Lake Maelar into the sea (in about 58° N. lat.), the shores are steep; and on the south and west coast, the generally low, alluvial lands are replaced by more rocky formations.

In the northern parts, the land rises gradually from the Gulf of Bothnia to the Kjölen range, belonging to the great Norwegian Fjeldmark, which constitutes the true watershed and natural boundary between S. and Norway. South of 62° N. lat., the slope is directed southward, attaining its lowest level in the vicinity of the three great lakes of Vener, Maelar, and Hjelmar, which, together with the great Vetter lake, nearly intersect the country from east to west; and south of these great inland waters, the surface is in general level, though ranges of high ground and detached hills occur.

The following are the areas and populations of the 25 läns into which the provinces are subdivided (in 1880 the total pop. was 4,578,901):

Län.	Area in Geog. Sq. Miles.	Population in Dec. 1871.
Stockholm	134·5	131,731
Upsala	94·7	101,731
Södermannland	122·4	136,977
Oestergötland	194·9	257,367
Jönköping	202·2	180,569
Kronoberg	180·7	159,258
Kalmar	209·1	234,597
Götland	57·	54,237
Blekinge	54·7	126,935
Kristianstad	117·9	233,492
Malmöhus	86·8	318,786
Halland	89·3	127,842
Göteborg and Bohus	91·8	233,689
Elfsborg	232·7	286,454
Skaraborg	155·6	254,691
Vermland	306·6	261,716
Oerobro	164·7	169,319
Vestmannland	119·9	115,695
Kopparberg	528·7	176,946
Gefleborg	351·	150,374
Vesternorrland	447·5	136,939
Jemtland	921·2	71,338
Vesterbotten	1122·5	93,154
Norbotten	1931·8	77,328
	8078·8	4,065,665
City of Stockholm	....	138,512
Total population		4,204,177

In 1878 S. ceded her only colony, St. Bartholomew (q. v.), to France (to which country it once belonged) on payment of the purchase-money agreed on.

S. may be considered to be divided into three distinct parts—viz., the northern or alpine region, the central or lake district, and the southern or mining district. The extreme south includes the only level and fertile tract, in which wheat can at all times be advantageously and extensively cultivated. The lakes of S. have been computed to cover nearly ⅛th of the entire area of the country. The largest are Lake Vener (q. v.); Lake Vetter (q. v.); and the Maelar Lake (q. v.). The rivers are generally short and rapid, and only made navigable by art. The largest is the Angermann Elv, which flows into the Gulf of Bothnia. The Cattegat is connected with the Baltic by means of an admirable system of canals, &c.

Temperature, Natural Products, &c.—The differences of climate in S. are necessarily very great, considering that its most northern parts are more than 2° within the polar circle, and its southern extremity 11° south of it, besides which many districts are so nearly surrounded by seas and lakes as to have the conditions of an insular position. Great extremes of temperature are common in different parts of S.: thus, while Stockholm has a mean annual temperature of 42°·2 Fahr., and Götteborg 46°·3, the summer temperature of the former is 60°·4 Fahr., and that of the latter 62°·13; and the winter temperature of the former only 25°·8, and that of the latter 31°·5 Fahr.

The heat of the summer, which is scarcely separated from the cold of the winter by either spring or autumn in the extreme northern districts, enables the inhabitants to cultivate barley, which is reaped within two months of the time of its sowing, although even the hardier cereals, as oats and rye, will not ripen above the parallel of 66° N. lat. Indeed, the climate of S. generally is unfavorable to the growth of grain, the annual yield of which frequently falls short of the wants of the population. The principal articles of cultivation are, in addition to the various cereals, potatoes, hemp, flax, tobacco, and hops, which are generally grown in sufficient quantities for home consumption. The forests are of great extent, covering nearly one-fourth of the entire surface, and rising at some spots to an elavation of 3000 feet above the level of the sea. The birch, fir, pine, and beech are of great importance, not only for the timber, tar, and pitch which they yield, but also from their supplying charcoal and firewood. Above the parallel of 64°, stunted bushes, berries, dwarf-plants, and lichens are the only forms of vegetation to be met with. The common fruit-trees, as cherries, apples, and pears, grow as far north as 60°, but the fruit seldom comes to great perfection except in the southern provinces; cranberries and other berries abound, however, in all parts of the country. Bears and beavers, which were formerly often met with, are becoming scarce; but wolves, lynxes, foxes, martens, squirrels, eagles, reindeer in the Lappmarks, &c., are still common; while the elk and deer are found in some of the forests, which abound in hares, woodcocks, blackcock, and various other kinds of small game; and Lemmings (q. v.) occasionally descend from the mountains in large numbers, and lay waste the low country. The lakes yield a great abundance of fish, 88 different kinds of sea and freshwater fish being brought to market. In 1880, there were in S. 466,000 horses, 2,240,800 horned cattle, 1,504,000 sheep and lambs, 112,000 goats, and 417,000 swine.

The mineral products of S., which are extremely rich, include some gold and silver (which, however, do not pay the cost of working), copper in abundance, iron of the finest quality, alum, vitriol, marble, sulphur, lead, plumbago, cobalt, nickel, zinc, and some coal of very inferior quality.

Next to agriculture, mining constitutes the most important branch of national industry, and in some provinces is the principal employment. The Danemora mines, in Upsala Län, yield a metal which is capable of being converted into the finest steel, and which is for the most part purchased for the English market. At Gellivare in South Lapland, enormous quantities of iron ore of superior quality have recently been extracted from mines, which promise to rival those in Upsala.

Ship-building forms an entensive branch of local industry. The merchant-sailing marine numbered, in 1880, 4327 vessels, with a tonnage of about 544,000; the number of vessels that cleared the Swedish ports in 1880 was 14,753, with a tonnage of about 2,537,500, of which half belonged to Sweden.

Exports and Imports.—The chief articles of export are, in the order of their value, timber (beams, deals, masts, spars, pit-props), iron and steel, oats and barley, butter, lucifer matches, cattle, sheep, swine, paper, wood-pulp, copper and zinc-blende. The imports are mainly coal, coffee, sugar, rye and flour, woollen manufactures and wool, dressed skins, herrings, mineral oil, machinery, pork, salt, spirits and tobacco. About half the total exports go to Great Britain, the countries next in order being France, Denmark, Germany, Belgium, Norway, Holland, Russia. About a fourth of the imports come from Great Britain, Germany sending nearly as much; next come Denmark, Russia, Norway, Holland, Belgium, United States, and France. The total value of the exports from S. between 1870 and 1880 ranged from £8,500,000 to £13,000,000; of the imports, from £8,000,000 to £17,000,000. Accounts are kept in *kronor*, each worth about 1*s*. 2*d*.

Revenue, &c.—The revenue is derived from direct and indirect taxation, state property, railways, customs, &c. The budget for 1881 gave the annual receipts at 74,995,000 *kronor*, or about £4,166,400, and the expenditure at the same figure; of which about 55 million *kronor* were for extraordinary expenses. The frequent surplus of expenditure, which is almost invariably due to the prosecution of national and public works, is formally sanctioned by the diet, which annually provides means for covering the deficit by the appropriation of certain state funds for the purpose, and by the levying of a general income-tax. In 1880, the national debt of S. was £12,238,700, nearly ⅘ths of which are held by foreigners.

Army, Navy, &c.—The Swedish army, which is nominally rated at about 170,000 men, has a special and peculiar organization, as it consists, in addition to the Värfvade or enlisted troops, of the 'Indelta,' or cantoned militiamen, who are maintained at the cost, and on the property, of the landed proprietors: each estate being mulcted according to its value or extent to maintain one or more men, and provide them with 'torps' or cottages, a certain portion of land, and a fixed rate of payment. In return, these reserve soldiers, who are for the most part married men, serve the proprietor as field-laborers in times of peace, except during the four weeks of each year in which they are called out for drill. In case of war, they can be sent with the companies in which they are enrolled into active service, and they are then paid by the crown. The rest of the army is made up of volunteers, who serve for six years, every Swede between the age of 20 and 25 years being moreover bound to serve in the *beväring* or National Guard. In addition to these corps, companies of volunteer free-shooters were created in 1861 for the general defence of the country. Including volunteers, the total military force of S. in 1881 was 202,785 men. The fleet consisted, in 1881, of 140 vessels (of which 56 were steamers), carrying in all about 360 guns. There are on an average 7800 men engaged in active service; while in time of war, a coasting merchant fleet of 3200 vessels can be called into requisition, together with a reserve of 25,000 men. The principal fortresses are Karlssten, Karlskrona, and Vaxholm near Stockholm. The military and other orders are the Seraphim, the Sword, the Northern Star, and the order of Vasa. The order of Charles XIII. embraces the highest rank of freemasons in Sweden.

Form of Government.—S. is a hereditary and constitutional monarchy, based on the fundamental law of 1809, by which it was decreed that the succession should be in the male line; that the sovereign should profess the Lutheran faith; and have sworn fi-

delity to the laws. The diet, which meets every year, and remains sitting for three or four months, is composed of two chambers, which are both elected by the people. The first chamber consists of 127 members, who receive no payment, and are elected for nine years, their number being, however, dependent upon the amount of the population. They must be possessed of an income of about £225, and have attained the age of 35. The second chamber is composed of 194 members elected for three years, on a lower scale of qualification as to property and age; and receiving payment for their attendance during each session of the diet, and for their traveling expenses. Election to both chambers is by ballot. The diet exercises a strict control over the expenditure of the revenue, fixes the budget, and has power to take cognizance of the acts of the ministers and crown officers. The king's person is inviolable, and he can exercise a veto on the decrees of the diet. He is the supreme head of the law courts, nominates to all appointments, can declare war, make peace, and conclude foreign treaties. He is assisted by a council of state composed of ten members, who are responsible to the diet.

Law, &c.—The administration of the law is independent of the state, and presided over by the chancellor of justice, *Justitie Kanslar*, appointed by the king, and an attorney-general *Justitie Ombudsmann*, appointed by the diet. There were 587,591 cases brought before the courts in 1870, the large proportion of which were merely for slight offences against the law. The expenses incurred annually for the support of the poor are about six million rixdalers, which is nearly covered by the regular income obtained by the rates imposed for the purpose.

S. is divided administratively into 25 läns, presided over by länsmen, or chief magistrates, and subdivided into 117 fögderin, and 517 länsmans districts. There are 90 chief towns (städer), only a limited number of which have the right of trading with foreign ports, and 19 market-towns (köpingar). Beside Stockholm, the capital (q. v.), only one town, Göteborg (71,000 in 1877), has a population of more than 50,000. Next in rank come Malmö, with 34,439; Norköping, with 27,226; Gefle, with 18,137; and Karlskrona, with 17,787 inhabitants. Upsala, a cathedral and university town, which is the most interesting spot in the kingdom, as the original seat both of Christianity and of the ancient Odinic faith, has a population of only 13,446.

Religion, &c.—The predominant form of religion in S. is the Lutheran; the official tables of the census for 1870 showing only 6440 persons who belonged to other forms of faith, of whom 1918 were Baptists, and 1836 Jews. The affairs of the church are administered by 1 archbishop (of Upsala) and 11 bishops, whose collective dioceses include about 2500 parishes, with about 3500 pastors.

Education, &c.—Education is universally diffused among the Swedes by the agency of *Fasta* (regular) and *Flyttanda* (ambulatory) schools in all the country districts. There were, in 1869, 2303 of the former, and 1206 of the latter kind, together with 3410 infant schools, which were attended in all by 679,128 children, and instructed by 5030 male, and 2115 female teachers. Public instruction is compulsory for all children, and the cost is defrayed by the nation. Ample means are supplied for a higher form of instruction in the Lärovärk or Gymnasia of the towns, and at the universities of Upsala and Lund. The Karolingska Institute at Stockholm is the medical college of S.; and there are numerous technical, military, and other special collegiate institutions in the principal towns of the kingdom. The transactions of the two learned societies, the 'Svenska Vetenskaps Selskap,' and the 'Svenska Akademie,' afford honorable testimony to the advanced condition of scientific inquiry in Sweden. The Royal Library of Stockholm, and those of Upsala and Lund, number about 100,000 volumes each. That of Upsala is contained in a special building, *Carolina Rediviva*, to which is attached a botanical garden arranged on the Linnæan system.

Roads, Railways, &c.—There were, in 1878, 12,000 English miles of highroads in S., and nearly double that length of way in parish and by-roads. In 1880, a length of 3570 English miles of railway had been opened. About two-thirds of the total mileage belongs to private companies, and one-third to the state. The number of passengers annually conveyed is about 2,000,000, and the receipts are about £500,000. In 1880, the telegraphic lines measured 5200 English miles, and besides the government telegraph-stations, there were more than 350 stations in connection with railways and belonging to companies; about 1,000,000 messages were transmitted, of which number about 550,000 were inland telegrams; and the receipts were, for the same year 1,205,000 kronor. There passed upwards of 60,000,000 letters through the post-offices of S. in 1880, when the receipts were near 5,000,000 kronor. There are 1800 post-offices in S.

History.—The legendary history of S. forms part of Scandinavian history. When we first hear of S., the country was inhabited by numerous tribes, kindred in origin, but politically separate. Two principal groups, however, are recognizable—*Goths* in the south, and *Swedes* in the north. These possessed in common a national sanctuary, the temple at Uppsala, which laid the basis of a later unification, for gradually the royal chieftains of Uppsala extirpated the inferior princes, the Härads and the Fylkis. Ingiald Hrada, the last ruler of the old royal family of the Ynglingar, who drew their origin from Njord, sought to establish a single government in Sweden, and perished in the attempt. To the Ynglingar followed, in Upland, the dynasty of the *Skioldungar*, which claimed to be descended from Skjold, son of Odin. Erik Edmundsson, who belonged to this dynasty, is said to have acquired the sovereignty of the whole of Sweden about the end of the 9th century. The dawn of Swedish history (properly so called) now begins, and we find the Swedes constantly at war with their neighbors of Norway and Denmark, and busily engaged in piratical enterprises against the eastern shores of the Baltic. See NORMANS and RUSSIA. Efforts to introduce Christianity (see ANSGAR) were made as early as 829 A.D., but it was not till 1000 A.D. that Olof Skötkonung, the Lap-king, was baptized, nor did the struggle between heathenism and the new religion cease till the burning of the temple of Upsala in the reign of Inge (1080—1112).

In 1155, Erik, surnamed the Saint, gave a powerful impetus to the diffusion of Christian doctrines, by building churches and founding monasteries. He undertook a crusade against the pagan Finns, and having compelled them to submit to baptism, and established Swedish settlements among them, he laid the foundation of the union of Finland with Sweden. Erik's defeat and murder in 1160, by the Danish prince, Magnus Henriksen, who had made an unprovoked attack upon the Swedish king, was the beginning of a long series of troubles, and during the following 200 years, one short and stormy reign was brought to a violent end by murder or civil war, only to be succeeded by another equally short and disturbed. At length, in 1389, the throne was offered by the Swedish nobles to Margaret, Queen of Denmark and Norway, who, having gladly availed herself of the opportunity thus opened to her of uniting the three Scandinavian crowns into one, threw an army into S.; defeated the Swedish king, Albert of Mecklenberg, who, on the deposition of his maternal uncle, Magnus, had been called to the vacant throne; and by the union of Calmar, in 1397, brought S. under one joint sceptre with Denmark and Norway. In 1523, S. emancipated itself from the union with Denmark, which, during the reigns of Hans and his son Kristian II (see DENMARK), had become hateful to the Swedes, and rewarded its deliverer, young Gustaf Vasa (see GUSTAVUS I.), by electing him king, and declaring its independence of Denmark. Gustaf Vasa found an empty treasury, a kingdom exhausted by war, a haughty nobility and clergy (who arrogated the right of electing the sovereign, and who claimed exemption from all imposts), and a people overburdened with taxation and bad government, and divided in regard to religion. On his death, in 1560, he left to his successor a hereditary and well-organized kingdom (in which the power of the nobles had been circumscribed, and that of the clergy broken, by the abrogation of Catholicism, and the firm establishment of the Reformed Church under the jurisdiction of the state), a full exchequer, a standing army, and a well-appointed navy. Trade, manufactures, arts, learning, and science owed their advancement in S. to this patriotic king.

The colossal labors of the great Vasa, in raising a semi-barbarous state to an honorable place among the civilized monarchies of Europe, were rendered almost useless by the crimes and misfortunes of his son and successor, Erik XIV., whose high intellectual powers were clouded by a wayward and revengeful nature, leading him finally to insanity. His cruelties and excesses led to his deposition in 1568, when his younger brother Johan ascended the throne, which he occupied for nearly a quarter of a century, dying in 1592, after a stormy reign, stained by the cruel murder of his unfortunate brother Erik, and distracted by the internal dissensions arising from his attempts to force Catholicism on the people, and to carry on war with the Danes, Poles, and Russians. Johan's son and successor, Sigismund, who had been elected king of Poland through the influence of the relatives of his Polish mother, after a short and stormy reign of eight years, which were spent in attempting to restore Catholicism in S., was compelled by the diet to resign the throne in 1599 to his uncle Karl, the only one of Gustaf Vasa's sons who inherited any share of his legislative and administrative talents. The policy of Karl IX. was to encourage the burgher classes at the expense of the nobility; and by his successful efforts to foster trade—in furtherance of which he laid the foundation of Göteborg and other trading ports—develop the mineral resources of the country, and reorganize the system of Swedish jurisprudence, he did much to retrieve the calamitous errors of his predecessors. The deposition of Sigismund gave rise to the Swedo-Polish war of succession, which continued from 1604 to 1660; and on the death of Karl in 1611, his son and successor, the great Gustavus Adolphus, found himself involved in hostilities with Russia, Poland, and Denmark. By the ability of his minister, Oxenstierna, the young king was soon enabled to conclude treaties of peace with his northern neighbors, and to

place the internal affairs of his kingdom in order (see GUSTAVUS II.); and although he justly ranks as one of the greatest military commanders of his age, the extraordinary number of benefits which he conferred on every department of the administrative system of S., entitle him to still greater renown as the benefactor of his native country. His death in 1632, on the field of Lützen, would have proved an irreparable calamity to S., had not the able administration of Oxenstierna, during the minority of Gustavus's daughter Christina, maintained the renown of the Swedish arms abroad, and the political reputation of the country among other states. The reign of Christina (q. v.) was disastrous in every act but that of her abdication.

The short reign of Karl X. was occupied in generally unsuccessful wars against Poland and Denmark; while the minority and long rule of his son, Karl XI.—from 1660 to 1697—was characterized by success abroad, and in the augmentation of the regal power, which was declared by an act of the diet to be absolute. His son Karl, known to us as Charles XII. (q. v.), succeeded, at the age of 15, to the power and dominions which his father's abilities had consolidated, but which, notwithstanding his own brilliant genius, he so deeply imperilled by his insatiable ambition, that at his untimely death in 1718, at the siege of Frederikshald, after a brilliant career of glorious but chequered military achievements, he left his country overwhelmed with debts, and disorganized by prolonged misrule. With him the male line of the Vasas expired, and his sister and her husband, Frederick of Hesse-Cassel, were called to the throne by election, but were the mere puppets of the nobles, whose rivalries and party dissensions plunged the country into calamitous wars and almost equally disastrous treaties of peace, and, under the leadership of the two great factions of the 'Hats,' or French party, and the 'Caps.' or Russian party, demoralized all ranks of society. The weak Adolphus Frederick of Holstein-Gottorp, who was called to the throne on the death of Frederick in 1751, and died in 1771, did little to retrieve the evil fortunes of the state; but his son, Gustavus III. (q. v.) (1771—1792), skilfully turned to account the general dissatisfaction of the people with the nobles, to destroy the factions of the Hats and Caps, and to recover the lost power of the crown. His extravagance, dissoluteness, and insincerity detracted, however, from his merits as a ruler, and raised up numerous enemies against him, through whose agency he was assassinated in 1792.

His son and successor, Gustavus IV. (q. v.), lacked the ability to cope with the difficulties of the times, and after suffering in turn for his alliance with France, England, and Russia, was forcibly deposed in 1809, and obliged to renounce for himself and his direct heirs the crown in favor of his uncle, Charles XIII., who saw himself compelled at once to conclude a humiliating peace with Russia by the cession of nearly a fourth part of the Swedish territories, with 1½ million of inhabitants. The early part of the reign of Charles, who was childless, was troubled by domestic and foreign intrigues to regulate the choice of an heir to the throne; and when, under the erroneous idea of conciliating Napoleon, the dominant party in S. elected General Bernadotte to the rank of Crown Prince, the latter assumed the reins of government, and by his steady support of the allies against the French emperor, secured to S. at the congress of Vienna, the possession of Norway, when that country was separated from Denmark. Under the able administration of Bernadotte, who, in 1818, succeeded to the throne as Charles XIV., the united kingdoms of S. and Norway made great advances in material prosperity and political and intellectual progress; and although the nation at large entertained very little personal regard for their alien sovereign, his son and successor, Oscar (1844—1859), and his grandsons, the late king, Charles XV., and the present king, Oscar II., who came to the throne in 1872, have so identified themselves with their subjects, that the Bernadotte dynasty has secured the loyal affections of every section of the united nations of S. and Norway.

SWE'DENBORG, EMANUEL, was born in Stockholm, January 29, 1688, and died in London, March 29, 1772. His father was Jesper Svedberg, subsequently Bishop of Skara. S.'s lifetime divides itself into two distinct periods; the first, ending with his 55th year, was given to business, science, and philosophy; the second, of nearly 30 years, was consecrated to theology and spiritualism. S. was educated at Upsal, and traveled for four years in England, Holland, France, and Germany. On his return to Sweden, he was appointed by Charles XII. to an assessorship of mines; and rendered some service to that monarch as military engineer. The S. family was ennobled in 1719, and the name changed from Svedberg to Swedenborg. S. is sometimes styled Count and Baron, but erroneously; he was neither, though he had a seat in the Swedish House of Nobles. His mind at this time was busy with mechanical and economical projects. He published short treatises on algebra, giving the first account in Sweden of the differential and integral calculus; on a mode of finding the longitude at sea by the moon; on decimal money and measures; on the motion and position of the earth and planets; on the depth of the sea, and greater force of the tides in the ancient world; on docks, sluices, and salt-works; and on chemistry as atomic geometry. In 1724 he was offered the professorship of mathematics at Upsal, which he declined from a dislike of speculative science. Abandoning his desultory studies, he remained silent for eleven years, and devoted himself to the duties of his assessorship and to a systematic description of mining and smelting, and the construction of a theory of the origin of creation. The result appeared at Leipzic in 1734, in three massive folios, beautifully illustrated, entitled *Opera Philosophica et Mineralia*. The second and third volumes describe the manufacture of copper, iron, and brass, and contain an exhaustive record of the best methods in use in last century.

The first volume, entitled *Principia, or the First Principles of Natural Things, being new Attempts towards a Philosophical Explanation of the Elementary World*, is an elaborate deduction of matter from 'points of pure motion produced immediately from the Infinite.' This was followed in 1734 by a treatise on *The Infinite, and the Final Cause of Creation; and the Intercourse between the Soul and the Body*, carrying the doctrine of the *Principia* into higher regions, and resolving the soul into points of motion, and one in substance with the sun. Dissatisfied with his conclusions, he determined to track the soul to its inmost recesses in the body. His studies in human anatomy and physiology with this end in view, appeared as *Œconomia Regni Animalis*, in two volumes, 1741, and as *Regnum Animale*, in three volumes unfinished, 1744—1745. At this point, his course was arrested, and he entered on his career as seer, by which he is known to fame. The particulars of the transition lay in obscurity until 1858, when G. E. Klemming, royal librarian, Stockholm, discovered S.'s diary, kept in 1744. It contains the record of a variety of dreams, visions, and strange communings. After that date, he professed to enjoy free access to heaven and hell. He resigned his assessorship in 1747, that he might devote himself to his office of seer. In 1749, he made his first public appearance in his new character in the issue in London of the *Arcana Cœlestia*, completed in 1756 in eight quartos. His life henceforward was spent between Stockholm, London, and Amsterdam, in writing and printing a variety of works in exposition of his experience and doctrines. There is little in any of these which is not comprised in the *Arcana Cœlestia*, and a few notes on its contents may serve as a description of the whole. With many digressions, the *Arcana Cœlestia* is a revelation of the inner sense of Genesis and Exodus. The early chapters of Genesis are a fragment of an older Word, preserved at this day in Tartary, and are not historical in a matter-of-fact sense. Adam signifies the most Ancient Church, and the Flood its dissolution; Noah, the Ancient Church, which falling into idolatry, was superseded by the Jewish.

The spiritual sense pervades the Scriptures, with the exception of Ruth, Chronicles, Ezra, Nehemiah, Esther, Job, Proverbs, Ecclesiastes, the Song of Solomon, the Acts of the Apostles, and the Epistles. No fault is found with these books, but inasmuch as they do not possess the internal sense, they are not the Word. The Scriptures are read in heaven in the spiritual sense, but as that sense treats exclusively of God and the human mind, it is void of every reference to earthly scenes, persons, and events. By reason of its symbolism of the inward sense, the letter of Scripture is holy in every jot and tittle, and has been preserved in immaculate perfection since the hour of its divine dictation. The Jewish dispensation having reached its period, God appeared in Jesus Christ. He assumed human nature in its basest condition in the Virgin, wrought it into conformity with Himself, 'glorified and made it divine.' The effluence from the redeemed humanity is the Holy Spirit. In a sense the reverse of Socinian, S. was a Unitarian. He saw God in the Saviour, and regarded Him as the sole object of worship. The Church initiated by the divine advent came to an end in last century, and S. witnessed the Last Judgment effected in the year 1757 in the World of Spirits. Then commenced a new dispensation, signified by the New Jerusalem in the Revelation, of which S. was the precursor, and his writings the doctrine. To the objection, that the doctrine is strange and novel, he replied, that mankind were not prepared for its reception, and that the early Christians were too simple to understand it.

One of the chief ends of his mission was the revival of the lost science of correspondences—the science of sciences in the most ancient times. The law of correspondence is universal; the natural world is the outbirth of the spiritual world, and the spiritual world of the invisible mental world. Unseen evil is manifested in things hurtful and ugly; unseen good, in things useful and beautiful. Man is a summary of nature; nature is man in diffusion; all things, therefore, in nature, in fire, air, earth, and water—every beast, bird, fish, insect, and reptile—every tree, herb, fruit, and flower, represent and express unseen things in the mind of man. The Scriptures are written according to correspondences, and by aid of the science their mysteries are

unlocked. By it, too, the constitution of heaven and hell is revealed. There are three heavens, consisting of three orders of angels: the first distinguished for love, the second for wisdom, and the last for obedience. All angels have lived on earth; none were created such. They are men and women in every respect; they marry, and live in societies in cities and countries just as in the world, but in happiness and glory ineffable. All in whom love to God and man is the ruling principle, go to heaven at death. Between heaven and hell, a perfect equilibrium is maintained. As there are three heavens, there are three hells, and every angelic society has an infernal opposite. Hell, as a whole, is called the Devil and Satan; there is no individual bearing that name. All in whom self-love is the ruling motive, go to hell. There is no resurrection of the earthly body. Every one passes to his final lot at death, some making a short sojourn in an intermediate state, designated the World of Spirits, where the good are cured of their superficial infirmities and intellectual mistakes, and where the evil are stripped of all their pretences to good.

S. professed to enjoy a numerous acquaintance with departed celebrities, and some of his verdicts on character are appalling; for example, he describes King David and St. Paul as amongst the lost, while Louis XIV. and George II. are distinguished angels. Nor did he confine his intercourse to ghosts from earth, but extended it to souls from the moon and planets, with the unfortunate exceptions of Uranus, Neptune, and the Asteroids. For these visions, enjoyed whilst sitting in his chamber, he had this explanation: although in the spiritual world there are *appearances* of space, there is nothing of the objective reality which here divides London from Melbourne. If one spirit desires to see another, the desire instantly brings them together. A good man is, as to his mind, in heaven, and an evil man in hell; and supposing the spiritual sight of either was opened—that is, if the eyes of the spiritual body, which transfuse and animate the material ones, were disengaged from their fleshly vesture—he would see his spiritual companions and the country where he would abide after death.

The grand and distinctive principle of Swedenborgian theology, next to the doctrine of the Divine Humanity, is the doctrine of life. God alone lives. Creation is dead—man is dead; and their apparent life is the Divine presence. God is everywhere the same. It fallaciously appears as if He were different in one man and in another. The difference is in the recipients; by one He is not received in the same degree as another. A man more adequately manifests God than a tree; that is the only distinction. The life of devils is God's presence perverted in disorderly forms. 'All things, and each of them to the very uttermost, exist and subsist instantly from God. If the connection of anything with Him were broken for a moment, it would instantly vanish; for existence is perpetual subsistence, and preservation perpetual creation.' By this law of life is explained man's self-consciousness, freedom, and personality. All these sensations are communicated from God to man. He dwells in man so cordially, that He gives him to feel that he lives of himself, even as He lives.

S. made no attempt to establish a sect. When he proclaimed the Christian Church at an end, his expectation was, that a new church would be raised up among the Gentiles; but towards the close of his life he was silent as to that hope, and spent his energies in attacking Protestant theology, as if bent on the conversion of Northern Europe. All his works were written in Latin, and received little attention from his contemporaries. Apart from his visions, there was nothing peculiar about Swedenborg. He was shrewd in worldly affairs, affable in society, and discussed politics and finance in the Swedish diet like a man of the world. He was never married. In diet he was a vegetarian.

Swedenborgians, or, as they designate themselves, 'The New Church signified by the New Jerusalem in the Revelation,' were first organized as a separate body in 1788 by Robert Hindmarsh, a printer in Clerkenwell, London, who was elected by lot to baptize and to ordain his comrades in the ministry. The Swedenborgians accept S.'s voluminous theological writings as nothing less than revelations from heaven. The body has not had a prosperous existence. The number of its registered members in Britain is little over 4000, divided into 58 congregations. These are chiefly in the large towns and in Lancashire; four are in Scotland, but none in Ireland. At one time, there were reputed to be a number of receivers of the doctrines of S. among the clergy of the Church of England. The translator of the *Arcana Cœlestia* was the Rev. John Clowes, rector of St. John's, Manchester, for sixty-two years. He died in 1831, and in the pulpit and numerous publications made no secret of his faith. In the United States, the Swedenborgians have nearly 100 societies, and about 5000 members. They chiefly exist in the northern states; and their largest congregation is in Boston. In France, Germany, Sweden, and Russia, there are Swedenborgians, but few and scattered. There is a Swedenborg Society, established in 1810, for printing and publishing S.'s works, with a house in London, and an income of about £200 a year. See the Life of S. by White (London, 1867), and various *Documents*, published by Prof. Tafel (ed. 1875).

SWEDISH LANGUAGE AND LITERATURE. See SCANDINAVIAN LANGUAGE AND LITERATURE.

SWEEPS, on Shipboard, are oars of great length used in large vessels during a calm, to enable the ship to obtain steerage-way.

SWEETBREAD, the Pancreas (q. v.) of an animal, used as food; it is highly esteemed as being both delicate and nutritious.

SWEET-BRIAR. See ROSE.

SWEET FLAG. See ACORUS.

SWEET GUM. See LIQUIDAMBAR.

SWEET-MEAT, a general term applied to such articles of food as consist chiefly of sugar.

SWEET PEA. See LATHYRUS.

SWEET POTATO. See BATATAS.

SWEETS, a term applied in England, and by the Board of Inland Revenue, to home-made wines, for the sale of which a special licence is granted. It is also a term in far more general use for lozenges, comfits, and other preparations of sugar well known to children: they are the *confitures* of the French.

SWEET SOP (*Anona squamosa*), a fruit of the same genus with the Custard Apple (q. v.). It is produced by a small bush, with lanceolate leaves, a native of the warm parts of America, and much cultivated in Brazil, the West Indies, and generally in tropical countries. The fruit is greenish, and resembles an artichoke in size, in form, and in its scaly covering. The pulp is soft, somewhat mealy, sweet, and luscious; with a musky aromatic odor and flavor. It is much used both in the East and West Indies, generally raw, but sometimes cooked. Notwithstanding its foreign origin, it has proved the staff of life to the people of Hindustan in seasons of famine. The seeds are acrid, and the powder of them is used to destroy insect vermin.

SWEET WILLIAM. See PINK.

SWEET WOOD. See CASCARILLA.

SWELL, in Music, a set of pipes in an organ with a separate key-board, and forming a separate department, which are capable of being increased or diminished in intensity of sound by the action of a pedal on a series of shades or shutters overlapping each other like Venetian window-blinds, within which the pipes in question are enclosed. On a well-constructed swell, a practiced performer can imitate not only a gradual *crescendo* and *diminuendo*, but also a *sforzando*, a very small opening sufficing to make an immediate burst on the ear; while, when the shutters are closed, an imitation of an echo is produced.

SWIETE'NIA. See MAHOGANY.

SWIFT (*Cypselus*), a genus of birds of the Swallow family. The distinctive characters of the group, of which the true Swifts are the type, are noticed in the article SWALLOW. The Swifts, like

Common Swift (*Cypselus apus*).

the swallows, are widely distributed, and some are only found in tropical countries; others are birds of passage, and spend the summer in colder parts of the world. Many of the S. group are often popularly called swallows, as that which produces the edible nests of the East Indies. In the genus *Cypselus*, as now restricted, the tail is generally forked, the legs and toes feathered, and very small and weak, all the four toes directed forwards. The birds of this genus pass most of their time in the air, and even copulate on the wing. The wings are longer than in any other bird; and the internal structure, even of the skeleton, is peculiarly adapted to prolonged flight. The anatomy more resembles that of humming-birds than of true swallows.—The COMMON S. (*C. apus*) is common in almost all parts of the north of Europe and of Asia in summer, retiring to tropical or subtropical regions in winter. It occurs even in Lapland. Its residence in its summer quarters is much shorter than that of swallows; and it is worthy of notice, that the S. is seldom to be seen along with any of the

swallows or martins, the different kinds choosing different localities, even although very close together.

The S. is easily recognized in its flight by the remarkably sickle-shaped wings, and its slight scream is very different from the twitter of the swallow. It is black, with a white throat. It makes its nest in holes of rocks or of walls, often in those of houses. The nest is formed of bits of straw, dry blades of grass, and bents, feathers, and other such substances, which are apparently glued together by a mucous secretion. The S. sometimes builds in hollow trees. Swifts, like swallows, seem to return to the same place to make their nest, year after year, and repair the old nest, instead of making a new one.—The ALPINE S., or WHITE-BELLIED S. (*C. alpinus*), is rarely seen in Britain, but is common in the more southern countries of Europe. It builds in high rocks, sometimes in steeples. It is larger than the Common S., and is the largest of the British *Hirundinidæ*. Its wings are even longer in proportion than those of the Common Swift. Its voice is sweet, not a scream like that of the Common Swift.—The AMERICAN S. (*Chætura pelasgia*) has the hind-toe directed backwards, and the tail-feathers stiff and pointed, as in woodpeckers. It is a small bird, not above 4¾ inches in entire length, but 1 foot in extent of wing. The general color is brownish black, with greenish reflections, the throat grayish white, the under parts grayish brown. The nest is made of small dry twigs, which the bird breaks off from the tree, and carries away in its feet; and they are attached by means of the saliva, to the rock, wall, or hollow tree where the nest is made. From its frequently building in chimneys, this species is known as the *Chimney Swallow* in North America. Great numbers often build together, sometimes choosing for this purpose an unused chimney in a town.

SWIFT, JONATHAN, the greatest of English satirists, and the most original writer of his age, was born in Dublin, but of English parents, on the 30th of November 1667. He was a posthumous child, reared amidst circumstances of abject poverty and dependence, the recollection of which galled his proud irascible spirit, and embittered much of his future existence. He was supported by relatives, and educated at Kilkenny school and Trinity College, Dublin. He proved a negligent and turbulent student, more intent on personal satires and political rhymes than academical honors; but he remained at college about seven years. He then removed to England, visited his mother in Leicestershire, and by her recommendation was admitted into the house of Sir William Temple, who had long known the Swift family. He seems at first not to have conciliated the regard of the retired minister, for in the following year (May 1690), Temple made an offer of the services of his protégé to Sir Robert Southwell (then about to proceed to Ireland as Secretary of State), recommending him as diligent and honest, qualified either to wait on Sir Robert as a gentleman, or to write under him as a clerk. No appointment followed; S. remained with Temple, studying hard, till 1694, when he went to Ireland, took orders in the church, and obtained a small living, which he threw up in two years, and returned to England, in consequence of Temple, who missed his society and assistance, urging him to come back. Temple died in 1698, and S. in the following year, published his posthumous works, after which he again repaired to Ireland, obtaining from Lord Berkeley some church preferments, including the vicarage of Laracor, worth in all about £400 per annum, which was all the professional income he enjoyed till he was appointed Dean of St. Patrick's, in his 46th year. Before this, he had written the wildest and wittiest and most powerful satirical work of the 18th c., *The Tale of a Tub* (1704), also a few essays on ecclesiastical subjects, some inimitable ridicule of astrology under the name of Isaac Bickerstaff, and poetical pieces possessing a peculiar vein of humor and description.

In 1710, he went over to the Tories, conceiving himself neglected by the Whig ministers, and exerted himself strenuously in behalf of his new allies, Harley and Bolingbroke. He wrote papers in *The Examiner* (1710); a *Letter to the October Club* (1711); *The Conduct of the Allies* (1712); *The Barrier Treaty* (1712), and innumerable pasquinades against the Whigs, whom he 'libelled all round.' He had become, as it were, a great and formidable power in the state, yet could extort no higher preferment for himself than the deanery of St. Patrick's. His party was overthrown by the death of Queen Anne; and in 1714, S. 'commenced Irishman for life,' with strong reluctance and disgust. In time however, he took interest in Irish affairs, and identified himself with Irish feelings and prejudices. Hatred to Walpole and the English government quickened his activity; and his resistance to Wood's copper coinage—a scheme for supplying Ireland with copper money by an English patentee—raised him to the highest pinnacle of popular favor. His *Drapier Letters* (1724) produced quite a ferment in Ireland, and compelled the government to abandon the scheme of the coinage. Two rewards of £300 each had been offered for the unmasking of the Drapier, but not a traitor, as he says, could be found to sell him. The triumphant author made his last visit to England in 1726, and published his *Gulliver's Travels*, the most universally popular of all his works. He next joined with Pope, Arbuthnot, and Gay in publishing three volumes of *Miscellanies*, after which he returned to Ireland (October 1727), and never left it again. He was subject to fits of giddiness and deafness, which increased in frequency and intensity as he grew old; he brooded over the anticipated madness which he foreboded would be his future lot; his temper always irritable and gloomy, became more violent and morose, the effect of cerebral disease, and his memory and other faculties gave way. There was also a deep and secret grief: the fate of two ladies, known as Stella and Vanessa, had been inseparably entwined with his own destiny; both had sacrificed for him all but honor, and had sunk under disappointed hopes and blighted affection.

We cannot here trace the painful story, which is still involved in mystery, but for a time the retribution of S. was terrible. He rallied, however, and wrote some of his best minor pieces after this period. Among these are *The Grand Question Debated; On Poetry, a Rhapsody; The Legion Club; Verses on the Death of Dr. Swift;* and that extraordinary prose tract, *The Modest Proposal*, a masterpiece of irony, in which he proposes to relieve the distresses of the poor Irish by converting their children into food for the rich. The last three years of S.'s life were passed in almost total silence in the hands of keepers. He died October 19, 1745.

It would be superfluous to attempt in our brief space to characterize the genius of the immortal Dean of St. Patrick's. Shakspeare alone among English authors has received a greater amount of criticism and annotation. From Johnson to Thackeray, the most brilliant critics and biographers have employed themselves in elucidating his strange and sad history, and in estimating his writings. As a consummate master of ridicule and irony, possessing great powers of wit, invention, illustration, and analogy; possessing also the dramatic faculty that enabled him to assume and portray varieties of character; and as writing a pure, perspicuous English style, unsurpassed for strength and simplicity, S. must ever be a model in our language and literature. His misanthropy, or degradation of human nature—his Yahoos, Strulbrugs, daring irreverence, and indelicacy, are of course indefensible. He had a total incapacity, as De Quincey remarks, for 'dealing with the grandeurs of the human spirit, with religion, with poetry, or even with science, when it rose above the mercenary practical.' His business was with the world—with the follies, vices, and absurdities of men. And his poetry is the same as his prose; it may come under his definition of a good style, 'proper words in proper places,' applied to ordinary topics, but is wholly wanting in passion, elevated feeling, and imagination. A complete edition of his works, in 19 vols., was published by Sir. W. Scott (1815). See also Roscoe's edition (1853), and *Life* (unfinished), by John Forster (1875).

SWI'LLY, LOUGH, an inlet of the Atlantic on the north coast of Ireland, in the county of Donegal, enters between Dunaff Head on the east, and Fanad Point, on which there is a light-house, on the west. It penetrates the country in an irregular, but generally south direction, is about 25 miles in length, and at its entrance, where it is widest, it is 3¾ miles broad. On the eastern shore is the small town of Buncrana, much resorted to for sea-bathing; and in front of which is a roadstead, capable of accommodating the largest men-of-war.

SWIMMING. The art of swimming is so exceedingly useful, not only as a bracing summer exercise, but as a means of preserving life, that it should be acquired by every young person. Considering the numerous risks run by all human beings, especially by the inhabitants of maritime countries, of being accidentally plunged into the water; and how greatly the chances of being saved are increased by the power of keeping one's self afloat for even five minutes, it is surprising that the art of swimming does not form an essential element of education among all classes. With our limited space, it would be needless to attempt giving directions that would be of any practical value. In many cities, there are now swimming-schools, where professional instruction may be had. When these are not available, any acquaintance who can swim will give his aid until the elementary movements and the necessary confidence are required. Even without help, by keeping in safe water, and by perseverance, the art will be acquired as by instinct.

SWI'NBURNE, ALGERNON CHARLES, one of the first of living English poets, is the son of Admiral Charles Henry Swinburne, by Lady Jane Henrietta, daughter of the third Earl of Ashburnham, and was born in London on April 5, 1837. He entered as a commoner at Balliol College, Oxford, in 1857, but left the university without graduating. His first literary venture, a volume published in 1861, containing two plays, *The Queen Mother and Rosamund*, attracted little attention; but *Atalanta in Calydon*, a tragedy, which appeared in 1865, at once established his reputation. Afterwards came *Chastelard*, a tragedy (1865); *Poems and Ballads* (1866); *A Song of Italy* (1867); *Siena* (1868); *Songs before*

Sunrise (1871); *Bothwell*, a tragedy (1874); *Erechtheus* (1875); and a new series of *Poems and Ballads* in 1878. S. belongs to what has been aptly called the 'fleshly school' of poetry, and even those who most admire his power of poetical expression, richness of coloring, and happy lyrical effects, must deplore the sensuous tone of his muse. He has also been severely animadverted upon for the wanton violence with which he attacks the most sacred beliefs of his fellow-men. His *Songs of the Springtides* appeared in 1880. A collection of his *Essays and Studies* was published in 1875; his *Note on Charlotte Brontë* in 1877; *A Study of Shakspeare* in 1879; *Songs of the Springtides* (1880); *Studies in Song* (1881). *Mary Stuart, a Tragedy*, (1881), taken in connection with *Chastelard* and *Bothwell*, completes a noble dramatic trilogy. In *Tristram of Lyonesse and other Poems* (1882), S. has drawn inspiration from the old Arthurian fountain; but the work is the most varied volume of verse that S. has produced.

SWI'NDON, an old market-town of Wilts, 77 miles west of London, with a large corn exchange. A mile north of the town is Swindon Junction, the great central establishment of the Great Western Railway Company. A considerable town has risen around the station, called the New Town, and consisting mainly of dwellings for the employés of the railway. There is a large and beautiful church, a public park, library, and mechanics' institution. Pop. of Old Town, (1881) 4696; of New Town, 17,669.

SWI'NEMÜNDE, a maritime and fortified town of Prussia, province of Pommern, is situated on the island of Usedom, at the entrance of the narrow channel of Swine, which connects the Grosses Haff (into which the Oder flows) with the Baltic. S., as in some sense the port of Stettin (q. v.), carries on a considerable commerce, and has also valuable fisheries, but it is chiefly noted for its excellent sea-bathing. The lighthouse of S. has a tower 200 feet high. Pop. of S. (1875) 8045.

SWING, a cognomen assumed by senders of threatening letters during the period when the irritation of the agricultural laborers of England against their employers was at its height—viz., from 1830 to 1833. The cause of this misunderstanding arose from a widespread belief on the part of the laborers, that the use of machinery would greatly lessen the demand for labor, and consequently produce a general reduction of wages; it was also intensified by the savage severity with which the game-laws were enforced, and by other hardships to which the laboring-classes in the country considered themselves unjustly subjected. As any inattention on the part of landlords or farmers to the demands contained in these threatening letters was almost invariably followed by the burning of stacks, farm-buildings, &c., the employers of labor became so terrified that implicit obedience was paid to the dictates of 'Captain Swing.' It is not to be wondered at that, with such encouragement, 'Swings' became numerous, and their demands more insolent; but the apprehension and punishment of a number of them gradually brought about a cessation of the outrages.

SWITHIN, SAINT, an English ecclesiastic of the 9th c., who was chaplain to King Egbert, and tutor to his son Ethelwulf, under whom, when he came to the throne, he held the office of Chancellor. He had the charge of the education of King Alfred, whom he accompanied to Rome. In 852, he was consecrated Bishop of Winchester. According to William of Malmesbury, he was 'a rich treasure of all virtues, and those in which he took most delight were humility and charity to the poor.' He adds, that he built several churches, and traveled through his diocese with his clergy on foot, and for the most part by night, in order to avoid the appearance of ostentation. The origin of the tribute called 'Peter-Pence' (q. v.) has been often assigned to S., and he is said to have procured an act of the Wittenagemote, enforcing, for the first time, the universal obligation of paying tithes. S. died on 2d July 862, and was buried, according to his own desire, in the churchyard of Winchester. A century later, he was canonized; and the monks, not considering this a fitting place of sepulture for a saint, exhumed his body, for the purpose of depositing it in Winchester cathedral; but this translation, which was to have taken place on the 15th July, was delayed in consequence of violent rains, which continued without intermission for forty days. Out of this circumstance arose the still current belief, that if rain fall on the 15th July, it will continue to rain for forty days. Experience certainly shows, that when a period of wet weather sets in about the summer solstice, it generally proves of considerable duration; and we find a similar superstition popularly attached in different countries of Europe to the festivals of various saints, which occur about the same period of the year. In France, the watery saints' days are those of St. Médard (8th June), and St. Gervais and St. Protais (19th June), the meteorological canon being—

> S'il pleut le jour de Saint Médard,
> Il pleut quarante jours plus tard ;
> S'il pleut le jour de St. Gervais et de St. Protais,
> Il pleut quarante jours après.

The rainy saint in Flanders is St. Godelièvе, and in Germany there are three saints' days to which this belief attaches, one being that of the Seven Sleepers.

SWI'TZERLAND (Ger. *Schweiz;* Fr. *Suisse;* It. *Svizzera*) is an inland country of Europe, situated between 45° 48′—47° 49′ N. lat., and 5° 55′—10° 30′ E. long. Its greatest length from east to west is 180 miles, and its greatest width from north to south, 130 miles. Its superficial area, without including lakes, is 15,233 sq. m., or one-fourth that of England and Wales. In 1880, the population of S. was 2,831,787. The following table gives the results of the census of 1870:

CANTONS.	Area in Eng. Sq. Miles.	Pop. Dec. 1870.

Surface.—S. is the most mountainous country of Europe. Its principal chains are the Alps (q. v.) and the Jura (q. v.). The former run from east to west along its southern or Italian frontier. Their ramifications fill more than one half of the country, and terminate along a line which may be traced from Vevey, on the Lake of Geneva, to Mount Moleson and Mount Napf, across Lake Zug, to the southern shores of the lakes of Zürich and Wallenstadt, and Sargans on the Rhine. The mean elevation of the highest chain is from 8000 to 9000 feet. The Jura run north-east from the western corner of Switzerland. They consist of a series of parallel ridges enclosing long and narrow valleys, and their mean elevation does not exceed 4000 feet. In the angle formed between them and the Alps, lies the plain of S., a tableland 100 miles in length, and from 20 to 30 miles in width, with a mean elevation of about 1400 feet above the sea. It is not absolutely level, but covered with elevations, which seem very unimportant, however, when contrasted with the huge masses of the Alps and Jura. It has been described, and not inaptly, as a corner of Southern Germany, penetrating like a wedge between France and Italy. The communication between the plain of S. and the German valleys of the Danube and Rhine is not, however, continuous. The plain on the east terminates in a third hilly tract—the Thur hill-country, which lies between the lakes of Zurich and Constance, and which, to some extent at least, forms a barrier between the plain of S. and Germany. The Jura, the plain, and the hill-country are, then, the great divisions of Northern Switzerland. The divisions of the Alpine region are more strongly marked in nature.

A glance at the map will show that the chains which overspread it radiate from a mountain knot lying to the west of the Grimsel Pass. They isolate and enclose (1) the valleys drained by the Rhone, which connect S. with Southern France; (2) Ticino, drained by streams which descend to the Po, and have at all times brought this country into close communication with Italy; (3) The Grisons, the most sequestered valleys of Switzerland, drained by the tributaries of the Rhine and Danube, and shut out by mountains from the lower basins of these rivers; (4) The Bernese Oberland, which slopes towards the western extremity of the Swiss plain; (5) The district of the Forest Cantons—Schwyz, Uri, and Unterwalden—surrounding the Lake of Lucerne, and which slope towards the eastern extremity of the plain, and seem a great mountain fortress erected in the very heart of Switzerland, to protect the plain against German invasion.

Geology is of little importance in explaining the general geog-

raphy of Switzerland. It may, however, be stated that in the Southern Alpine region, the rocks are crystalline; that in the Northern Alpine region, they belong to the Jurassic and other Upper Secondary strata; and that in the plain and a great part of the hill-country, they consist of loose Tertiary sands and clays, which supply the best agricultural soils of Switzerland. Those rocks and formations in which mines and coal chiefly abound are absent.

Climate.—In S., the climate chiefly varies with elevation above the sea-level. At a height exceeding 9500 feet, the mountains are covered with perpetual snow, which descends along the hollows in Glaciers (q. v.) to a much lower level, and in this way covers the elevated part of the country with a vast sea of ice. Below the level of perpetual snow, the surface of S. has been divided into a series of belts, characterized by different climates and productions. The highest of these, lying between the snow and the level of 6900 feet, has been called the Upper Alpine Region. In it, the glaciers fill the valleys, but plants clothe the scanty soil of the ridges. The second or Lower Alpine belt descends to 4800 feet. It is a country of pastures, in which shrubs, but no trees make their appearance. The Righi Pass, the Grimsel Hospice, and the Splügen are included in it. The third belt descends to 4350 feet. The meadows still abound in it, but forests of firs and maples in many parts replace them. It includes Urfenthal and Oberengadin. The fourth belt sinks to 3000 feet. The forests still abound, the beech being the prevailing tree. The meadows are excellent, and rye and barley are successfully cultivated. It includes Weissenstein, Grindelwald, and Engelsberg. The fifth belt lies above 1800 feet. In it the oak and walnut are the characteristic forest trees. Spelt and the best wheat are cultivated. It includes Bern, Coire, and St. Gall. The last belt sinks to 750 feet. In it the chestnut is the characteristic tree; the mulberry and the vine are extensively cultivated, and wheat is the grain chiefly grown. This belt includes the greater part of the Swiss plain, and sinks to its lowest level in the Valley of the Rhine, between Constance and Basel, and the banks of Lake Zürich and the Lago Maggiore. In the last district, the vegetation is that of Northern Italy. At a higher elevation than 6400 feet, S. is only inhabited by herdsmen during the summer months. At this limit, however, permanent abodes begin to make their appearance; and at 4000 feet there are many villages. The most populous part of S., however, lies between 1250 and 2150 feet. The temperature of this region is fairly represented by that of Zürich, which we will compare with that of London. The temperature of Zürich is in winter 30·34°; in spring, 47·25°; in summer, 64·15°; in autumn, 49·05°; for the year, 47·95°. The temperature of London is in winter, 38·22°; in spring, 48·34°; in summer 61·74°; in autumn, 50.29° for the year, 50·50°.

Productions.—In S., where good coal is not to be had, and where the houses are built of wood, the forests, which cover one-sixth of the whole surface, acquire very great importance. Wood-cutting is one of the chief employments of the people. The trees cut down in the highlands are deprived of their branches, and shot with inconceivable rapidity over the slopes to the valleys below, whence they are removed by rafts, not only to different parts of S., but to France and Germany. It is, however, the mountain-pastures and the meadows, forming two-fifths of the whole surface of the country, that supply the chief occupations of the people—those of herdsmen and shepherds. During the summer, the cattle are driven into the mountains, and tended by herdsmen, who take up their abode in the rude wooden huts known as *châlets*, and there the butter and cheese are made. In summer, it is estimated that there are in S. upwards of a million of horned cattle, one-fourth of which consists of milch cows. The produce of the dairy annually is valued at between one and two millions sterling. The best breeds of cattle are those of Saanen and Simmenthal in Bern, Gruyères in Freiburg, Schwyz, Zug, Entlebuch, Pralligau in the Grisons, and Glarus. The best cheese is made at Emmen, Saanen, Simmenthal, Gruyères, and Ursern. The sheep of S. are of inferior breed, and their wool is short and coarse; but the goats are numerous and fine. More than two-thirds of S. does not supply corn enough to feed its inhabitants. The plain, however, is a fertile agricultural country. In Vaud and Neufchatel, the cultivation of the vine is the chief occupation of the people; and in the Thur hill-country, more particularly on the shores of the Lake of Constance, there are extensive orchards, in which are prepared cider and *kirschwasser*, the latter being a liquor largely consumed in Switzerland. It will give some idea of the extent to which S. is cultivated to state, that out of every 100 sq. m. of surface, 30 are occupied by rocks, glaciers, and water; 20 by hill-pastures; 17 by forests; 11 by arable lands; 20 by meadows; and 1 by vineyards. In the uncultivated part of the country, the bear, the wolf, and the larger birds of prey are still met with; and the Chamois (q. v.) is hunted. The rivers and lakes abound with fine fish, and more especially with trout.

Manufactures.—The manufacturing districts are not scattered over the whole surface of the country; they are met with only on the northern frontier. The chief manufactures are: at Zürich, silk-stuffs, to the value of £1,600,000 annually, and cottons; at St. Gall and Appenzell, cottons; in Aargau and Glarus, cottons, linens, silks, and hosiery; at Basel, silk-stuffs to the value of £1,400,000, leather, paper, and tobacco; in Aargau and Lucerne, straw-plaiting; in Neufchatel, watch-making and cotton-printing; in Geneva, watch-making and jewelry. Although S. is inland, its commerce in proportion to population has long exceeded that of any other continental country. The chief imports are corn, salt, salt-fish, raw silks, and cotton, fruits and tropical produce, and the metals employed in watch-making. The exports are wood and charcoal, cattle, tallow, cheese and butter, silks and cottons, watches and jewelry. Internal communication has long been facilitated in S. by excellent roads, and every advantage has been taken of the lakes to introduce steam-navigation. The plain is now overspread from one end to the other with a network of railways, which in many directions send ramifications into the Alpine valleys, thus connecting closely all parts of the country.

Government.—Hitherto, the Swiss have been very much split into distinct communities by the great mountain-chains which separate the cantons. One of the results has been the weakness of the central power. Each valley has been entrusted with the making of its own laws, and the management of its own local affairs. The cantons are, in fact, to this day in a great measure separate states. They are divided into two classes, absolute democracies and representative democracies. In the former, the chief power belongs to the *Landesgemeinde*, an assembly of the whole adult male population, which meets once a year, to pass laws, and to regulate the taxes and expenditure of the canton. Url, the Unterwaldens, Appenzell, and Glarus have constitutions of this kind.

In the Grisons and the Valais, the people may be said to possess similar powers, as all measures must be approved of by them. In the other, the representative cantons, a great council is elected by the people, and to it are deputed most of the powers of the Landesgemeinde. These local assemblies produce a remarkable effect on the Swiss people. Their debates have an importance far beyond that of an English town-council, or even of a colonial parliament, for their power is infinitely greater, and the population are more immediately interested in them. To the interest they excite is no doubt to be attributed in a great degree the intelligence and public spirit of the Swiss. Their greatest disadvantage lay in the power they formerly had to levy war against each other, and to resist the general government in conducting the foreign policy of the country. But these defects have been to a great extent remedied by the constitution of 1848, which forms the basis of the present constitution, which dates from 1874. It handed over the control of the army, the conduct of foreign affairs, the settlement of disputes between the cantons, and the management of the police and post-office, to a federal assembly (*Bundes Versammlung*) representing all the cantons. How far this assembly is entitled to interfere with the legislative action of the cantons, has not been very distinctly defined, but the tendency of legislation since its formation has been rather to trench than otherwise on their prerogatives. The federal assembly consists of two chambers—1st, the State Council (*Stände Rath*); 2d, the National Council (*National Rath*). The former is composed of 44 members, 2 representing each canton; the latter, of 135 members, elected by the cantons in the proportion of 1 to 20,000 inhabitants. These bodies depute the executive authority to the federal council (*Bundes Rath*), consisting of seven members, and holding office for three years. The president is merely one of the council, and he has none of the quasi-royal privileges of the American president. There is also a court called the federal tribune (*Bundes Gericht*), which acts as a high court of appeal, and consists of 9 members elected by the federal assembly.

Different systems of law still prevail in the different cantons, which to some extent resemble each other, the most of them having grown out of the old German codes. Except in a few frontier cantons, the Roman law has not been much regarded. Until 1874, the law of the Catholic cantons prescribed, for certain offences, various degrees of corporal punishment, exposure on the pillory, and public penance in the churches; but in that year capital and corporal punishment was abolished throughout the confederation. In 1879 the cantonal governments were granted the right to restore capital punishment. In S., property is much subdived; of 485,000 heads of families, about 465,000 possess landed property.

There is no standing army in S., but every citizen is obliged to serve as a soldier, and military drill is taught at all the schools. The swiss regular force numbers 120,000; the reserve, 95,000. The imports from the surrounding countries, France, Germany, Austria, Italy, have an annual value of about 500,000 francs; while the exports to these countries amount in value to about 8,000,000 francs. The estimated national revenue amounted (1880) to 40,599,000 francs, and the expenditure to 40,782,000 francs.

Language and Religion.—In the sequestered valleys of the Grisons, two-thirds of the population still speak a Latin dialect known as the Romaunsh; Italian dialects have penetrated up the valleys of Ticino; French patois has invaded Western S., by the Rhine and the valleys of the Jura, to Laufen, the frontier of Soleure, Lake Morat, the Upper Saane, and Siders in the Valais. In the rest of S., the dialects are German. Of every 1000 Swiss, 702 speak German, 226 French, 55 Italian, and 17 Romaunsh. The Swiss Reformation spread chiefly from Basel, Bern, and Geneva, and the chief Protestant districts are the countries communicating with these towns. The Alpine region is almost entirely Roman Catholic, the seven Catholic cantons being Lucerne, Zug, Schwyz, Uri, Unterwalden, Valais, and Ticino. Out of 1000 Swiss, 411 are Roman Catholics, 587 Protestants, and 2 Jews.

Education.—In no country is elementary instruction more widely diffused. Parents are compelled to send their children to school or have them privately taught, from six to twelve. There are universities on the German model at Basel, Bern, and Zürich, and on the French plan a university at Geneva and academies at Lausanne and Neufchatel. The number of clubs for scientific and literary, musical and social purposes, is most remarkable. There are few scholarly pursuits which are not represented by societies in Switzerland. The local political assemblies and other public meetings give ample employment to the newspaper and periodical press. In S. there are 500 journals and reviews, 250 of which are political journals, and the remainder are devoted to literature and science. There are 40 daily papers. This active intellectual life is chiefly confined to the Protestant cantons.

History.—S. was in Roman times inhabited by two races—the Helvetii, supposed to have been Celts, on the north-west; and the Rhætians (of whose origin we know nothing), on the south-east. After the conquest of Gaul, both races adopted the language and habits of Rome. When the invasions took place, the Burgundians settled in Western S.: while the Alemanni, another Germanic tribe, took possession of the country east of the Aar. A third Teutonic people, the Goths, entered the country from Italy, and took possession of the country of the Rhætians, which nearly corresponded with the Grisons. The Burgundians adopted Christianity in the end of the 5th c.; the Helvetti retained their old pagan creed until the 7th c., when they were converted by Irish monks, who founded abbeys and churches, which survive to our own time. S., in the early part of the middle ages, formed part of the German Empire, and feudalism sprang up in the Swiss highlands even more vigorously than it did elsewhere. During the 11th and 12th centuries, the greater part of S. was ruled on behalf of the emperors by the lords of Zähringen (q. v.), who did much to check civil wars, and to promote the prosperity of the towns. They, however, became extinct in 1218, and then the country was distracted by wars, which broke out among the leading families. The great towns united in self-defence, and many of them obtained imperial charters. In 1273, Rudolf of Hapsburg, a Swiss nobleman who had favored the independence of the towns, became emperor. After doing so, he continued the same policy; but his son, Albert I. (q. v.), took another course. He attacked the great towns, and was defeated.

The leading men of the Forest Cantons, which for ages had yielded a merely nominal recognition of the empire, and had acknowledged no feudal superior, met on the Rütli meadow, on 7th November 1307, and resolved to expel the Austrian bailiffs or landvögte. See TELL. The war terminated in favor of the Swiss at Morgarten in 1315. Schwyz, Uri, and Unterwalden, with Lucerne, Zürich, Glarus, Zug, and Bern, eight cantons in all, in 1352, entered into a perpetual league, which was the foundation of the Swiss Confederation. Other wars with Austria followed, which terminated favorably for the confederates at Näfels (q. v.) and Sempach (q. v.). In 1415, the people of the cantons became the aggressors. They invaded Aargau and Thurgau, parts of the Austrian territory, and annexed them; three years later, they crossed the Alps, and annexed Ticino, and constituted all three subject states. The Swiss were next engaged in a struggle on the French frontier with Charles the Bold of Burgundy. They entered the field with 34,000 men, to oppose an army of 60,000, and yet they were successful, gaining the famous battles of Granson and Morat in 1476. In 1481, the towns of Freiburg and Soleure were admitted into the confederacy. In 1499, the Emperor Maximilian I. made a final attempt to bring S. once more within the bounds of the empire. He sought to draw men and supplies from the inhabitants for his Turkish war; but in vain. He was defeated in six desperate engagements. Basel and Schaffhausen (1501), and Appenzell (1513) were then received into the Confederation, and its true independence began. The abbacy of St. Gall, the cities of St. Gall, Mühlhausen, and Bienne became associated states, with a vote at the Diet. Geneva, Neufchatel, Valais, and the Grisons, also became associated states, but without a vote.

New troubles sprang up with the Reformation. Zwingli began to preach in the beginning of the century; and Zürich, in 1523, adopted his opinions, and was followed by Bern and other cantons of the north. The Forest Cantons remained attached to the Church of Rome. War broke out in 1531, between the Catholics and Protestants, and the former were successful at Cappel, where Zwingli was slain. This victory to some extent settled the boundaries of the two creeds in Eastern Switzerland. In 1536, however, Bern wrested the Pays de Vaud from the Dukes of Savoy, and annexed it to their own territory. In the same year, Calvin settled at Geneva, and the Reformed doctrines spread throughout Western Switzerland. During the Thirty Years' War, Bern, which had become, since the conquest of Vaud, the leading canton, and Zürich, contrived to maintain with great skill the neutrality of S.; and in the treaty of Westphalia, in 1648, it was acknowledged by the great powers as a separate and independent state. At this period, the Swiss, in immense numbers, were employed as soldiers in foreign service, and the record of their exploits gives ample evidence of their courage and hardihood. Internally, there was great stagnation. The constitution of the larger cantons became more aristocratic, that is to say, the mass of the people lost their power over the governing bodies. In Zürich, Schaffhausen, and Basel, the governing councils were elected by the corporations; and in Bern, Freiburg, Soleure, and Lucerne, a few families had acquired permanent rule. At the end of last century, there was widespread discontent with this state of matters; but the French Revolution broke out, and wars followed, which left no time for its manifestation. In 1798, S. was seized by the French. At the peace of 1815, its independence was again acknowledged. The new Confederation was divided into 22 cantons, each of which was represented in a Diet, which was appointed to hold its annual meetings alternately at Bern, Zürich, and Lucerne.

The old abuses which had crept into the constitutions of the cantons were revived, and representation in most of them became based on property qualifications. Officials, the aristocracy, and the clergy joined to oppose innovations, and succeeded in doing so until 1830, when the French revolution broke out. Armed demonstrations were made against the towns, and universal suffrage was generally conceded. Basel town, however, held out; but the difficulty was settled by the separation of the town and country districts—the former remaining conservative, the latter becoming democratic. Geneva and Neufchatal retained their old constitutions. The result of the changes was, however, that ⅘ds of the whole population were allowed to take part in public affairs. The consequences were not what had been expected by the liberals, who found that they had not yet the means of strengthening the central power. In 1839, at Zürich, where Dr. Strauss had been appointed a professor of theology, a mob of peasants, headed by the Protestant clergy, overturned the government. In Aargau, a struggle took place between the liberals and the Ultramontane party, which was settled, after long discussion, by an unsatisfactory compromise. In Valais, where universal suffrage had put power into the hands of the reactionary party, a war took place, in which the latter were victorious. They then ruled with a strong hand, and actually forbade the celebration of Protestant worship within the canton. In Lucerne, the headquarters of the Jesuits, the Ultramontane party acted even more extravagantly; they so persecuted their political opponents, that the latter were compelled to leave the canton. These measures caused the greatest discontent.

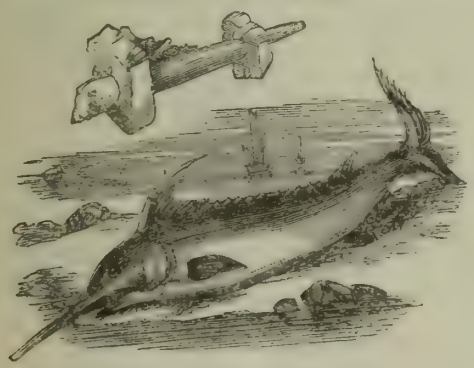
In 1844, a proposal was made in the Diet to expel the Jesuits; but that body declined to act. The radical party then determined to resort to force; they organized bodies of armed men, called the Free Corps, which invaded the Catholic cantons; but they were defeated. Changes favorable to them took place in some of the cantons. The Catholic cantons then formed a league, named the Sonderbund, for defence against the Free Corps. There was a general clamor for its suppression; but in the Diet, only 10½ votes were in favor of that measure. The ruling party in Geneva had been with the majority, and this conduct led to a revolution in that city. One vote was thus gained against the Sonderbund. St. Gall added another; and a majoriety in the Diet, in 1847, declared the illegality of the Sonderbund, and decreed the expulsion of the Jesuits. In the war which ensued between the federal army and the forces of the Sonderbund, the former were victorious at Freiburg and Lucerne. The leagued cantons were made liable in all the expenses of the war, the Jesuits were expelled, and the monasteries were suppressed. An attempt was made by diplomatic notes to intimidate the Swiss government, but the revolution of 1848 broke out, and prevented further interference. In the same year, the radical party, convinced of the necessity of a more powerful central government, carried the constitution of 1848. Subsequently, a rebellion took place against the king of Prussia, as Prince of Neufchatel. The canton was declared a republic, with a constitution similar to that of the other Swiss states. The king of Prussia protested in vain; but in 1857 he withdrew all opposition, and remained satisfied with the bare title of Prince of Neufchatel, which he still retains. The new federal constitution

adopted in 1874 confers greater power on the federal body at the expense of the several cantons.

SWI'VEL, is a gun constructed, as regards its carriage, to turn on a pivot, or on two concentric iron rails. Its use is on shipboard or in a fortress.

SWORD, a well-known weapon of war, the introduction of which dates beyond the ken of history. It may be defined as a blade of steel, having one or two edges, set in a hilt, and used with a motion of the whole arm. Damascus and Toledo blades have been brought to such perfection, that the point can be made to touch the hilt and to fly back to its former position. In last century, every gentleman wore a sword; now the use of the weapon is almost confined to purposes of war. In the British army, all officers and sergeants, with troopers of cavalry, wear swords for cutting and thrusting. In the navy, all officers wear similar swords; and the men, in time of action, heavy-backed swords, called *cutlasses*. In the French service, nearly all troops wear a combination of the sword with the bayonet, called a sword-bayonet.—For various sorts of swords and their uses, see RAPIER, CUTLASS, BROADSWORD, SCIMITAR, SABER, &c.; FENCING.

SWORD-FISH (*Xiphias*), a genus of fishes of the family *Scombridæ*, having the upper jaw remarkably elongated and compressed, in the form of a sword or dagger. The body is rather of a long shape, and covered with very small scales. There are no teeth. There is one long dorsal fin. The tail-fin is large and forked. There are two genera, *Xiphias*, destitute of ventral fins; and *Histiophhorus*, which possesses ventral fins. The common S. (*Xiphias gladius*) is plentiful in the Mediterranean, and in the warmer parts of the Atlantic; sometimes, but rarely, seen on the British coasts. It is bluish black above, and silvery white on the belly, the one color passing gradually into the other. It is highly esteemed as an article of food, especially when young. It is harpooned by the fishermen of the Mediterranean, and is powerful enough to drag a boat about for many hours after being struck. It has been said to attack the whale with its sword, but this is extremely improbable. Its food consists in great part of squids and cuttle-fish. The use of the sword is unknown. Instances not unfrequently occur of ships' bottoms being perforated by the sword of the S., but there is no good reason to think that an intentional attack is ever made.—Other species of S., belonging to genera closely allied to *Xiphias*, are found in the seas of different parts of the world.



Sword-fish (*Xiphias gladius*):
With section of a ship's timbers perforated by the 'sword.'

SY'BARIS, and CRO'TON or CROTONA, two celebrated Greek colonies in Magna Græcia (q. v.). The former—founded 720 B.C., by Achæans and Trœzenians—was situated in the south of the Lucanian territory, between the rivers Crathis (*Crati*) and Sybaris (*Coscili*), about 3 miles from the Tarentine Gulf; and the latter—founded 710 B.C., by Achæans—about 50 miles south-south-east on the coast of Bruttium. All that is certainly known concerning these cities before the destruction of the former is, that they both rapidly increased in size, wealth, and power, extending their dominions across the peninsula, and founding other colonies, at the same time preserving the most friendly terms with each other. S. is said to have been 6 miles in circumference, and Croton 12 miles; the former being notorious for the excessive and fastidious luxury of its inhabitants (hence the term Sybarite), and the Crotoniates celebrated for the perfection they reached in athletic exercises—the famous athlete, Milo (q. v.), having been a native of Croton. Somewhere between 540—530 B.C., Pythagoras (q. v.) settled at Croton, and exercised very considerable influence over the aristocratic government. About 510 B.C., a democratic leader, Telys, deposed the oligarchy of S., banished 500 of the leading citizens, and assumed the tyranny of the city. The banished citizens having taken refuge in Croton, Telys demanded their surrender, and on being refused, declared war against that city. The Sybarites, with an army said to have amounted to 300,000, met 100,000 Crotoniates, commanded by Milo, at the river Træis, were completely routed, and their city obliterated by the latter changing the course of the Crathis, so as to sweep it away. About 443 B.C., Thurii was founded near the sight of Sybaris. After the destruction of S., Croton appears to have gradually declined, suffering much from internal convulsions (see PYTHAGORAS), as well as from the disasters which befell it in its wars with the Locrians, Rhegians (480 B.C.), and Bruttians, and also in those of Dionysius (q. v.) of Syracuse and Pyrrhus (q. v.). Its ruin was completed in the second Punic war; and although, in 194 B.C., it was colonized by Roman citizens, it never again rose to be a place of any importance. Croton, in the time of Herodotus, and at a later period, was famous as a medical school.

The modern town of Cotroné, standing very near the site of the ancient town, has a population of 6878.

SY'CAMINE, a tree mentioned in Scripture, and supposed to be the Black Mulberry (q. v.).

SY'CAMORE, or SYCOMORE (*Sycomorus*), a genus of trees of the natural order *Moraceæ*, regarded by many botanists as a mere sub-genus of *Ficus* (see FIG), and differing from the true figs only in the elongated, straight, thickened, and club-shaped stigma.

Sycamore (*Acer pseudo-platanus*), showing leaves, flowers, and fruit.

The species are chiefly African, but the geographical range extends also into the west of Asia. Some of them attain a large size and a great age. The EGYPTIAN S. (*S. antiquorum*, or *Ficus sycamorus*), supposed to be the S. of the Bible, is a large tree, very abundant in Egypt and in some parts of the west of Asia, often planted near villages for the sake of its shade, its wide-spreading head sometimes covering a space 40 yards in diameter. The figs are top-shaped, and grow in clustered racemes on the trunk and oldest branches. They are sweet, well flavored, and somewhat aromatic. The wood is light, porous, and of little value. It has been supposed that the cases of Egyptian mummies are made of it, but this is disputed. Other species are found in Abyssinia, South Africa, &c.

The sycamore tree of Britain is a species of Maple (q. v.). In some parts of North America, the same name is given to the Plane (q. v.) of that country, *Platanus occidentalis*.

SY'DENHAM, a chapelry in the parish of Lewisham, county of Kent, with a station on the London and Croydon Railway, 8 miles south of London. It has become of world-wide celebrity in connection with the Crystal Palace, which was erected here in 1854, chiefly from the materials of the building of the Great Exhibition (1851). The cost of the erection and appointment of the Crystal Palace amounted to nearly £1,500,000. The building is 1600 feet long, 380 wide, and at the center transept 200 feet high. The chief arts and sciences illustrated by the collections within the Palace and grounds, are Sculpture, Architecture, Painting, and Photography, Mechanics and Manufactures, Botany, Ethnology, Palæontology, Geology, and Hydraulics. There are two concert-rooms, within the larger of which, performances have taken place at which there were 5000 vocalists and instrumentalists. The park and gardens occupy nearly 200 acres, and are adorned with sculptures, stone balustrades, &c., and fountains which are perhaps the finest in the world.

SYDENHAM, THOMAS, a great English physician, was born of good parentage, in 1624, at Winford Eagle, Dorsetshire, and was educated at Magdalen Hall, Oxford. According to the well-known French surgeon, Desault, he afterwards studied at Montpellier. He graduated at Oxford as Bachelor in Medicine in 1648. Through the interest of a near relative, he obtained a fellowship of All Souls College, and there continued to prosecute his

medical studies. He left the university without taking a Doctor's degree, which, indeed, he did not obtain till some time afterwards at Cambridge. He settled as a practitioner at Westminster, and practised so successfully that, when only 36 years of age, he already enjoyed the reputation of being one of the first physicians of the period. In his later years, he was much afflicted by gout, which at length carried him off on December 29, 1689. He was buried in St. James's Church.

S. was not profoundly accomplished as a man of science; even in his own age, deficient as it was in the advanced development to which the researches on which medicine is based have now attained, he was inferior to several of his contemporaries; but in sagacity of observation and accuracy of diagnosis he was unsurpassed. His skill and his philosophic cast of mind secured him the admiration and friendship of Locke; and his contributions to the literature of his profession received the praise of Haller and Boerhaave. His writings have been often republished both in England and on the continent, the edition entitled *Opera Medica*, which appeared at Geneva in 1716, being the best. Fevers were the department of medicine on which he first bestowed his attention; and before he had been many years in practice, he published, in 1666, his celebrated treatise entitled *Methodus Curandi Febres Propriis Observationibus Superstructa*. This was afterwards reprinted in 1675, with the observations accumulated in the interval. His treatment of the then destructive malady of smallpox was especially felicitous, substituting, as he did, for the stimulating regimen in vogue, the antiphlogistic method of cool air and salines. The most scholarly translation of his works into English is that of Dr. R. G. Latham, published in the Sydenham Society's series, to which he gives its name.

SY'DNEY, the capital of New South Wales, and the oldest city in Australia, is situated on the southern shores of Port Jackson, in lat. 32° 52′ S., long. 151° 11′ E. The first party of British settlers that reached New Holland were landed at Botany Bay on January 20, 1788. The spot which they here selected being found ineligible, it was abandoned a few days afterwards, and the infant settlement was transferred to a point about seven miles further to the north, to the place where S. now stands. The choice of the new locality was chiefly determined by the circumstance of a stream of fresh water being found there, flowing into the deep inlet known as Sydney Cove, one of the numberless bays into which the basin of Port Jackson is divided. This last-mentioned magnificent expanse of water, completely land-locked, and admitting vessels of the largest size, extends for some 20 miles inland, ramifying in every direction. Its bold and rocky shores present a succession of picturesque and beautiful landscapes. The cliffs which form the general outline of the harbor often rise to a height of from 200 to 250 feet. In other points, the coast presents a lower level, consisting of a series of terraces and smooth sandy beaches. Perhaps there are few positions on the habitable globe more obviously suitable for the foundation of a great metropolis. Situated at a distance of about 8 miles from the sea, the whole circumference of the bay round which it is built forms a series of natural wharfs, where vessels of 2000 tons burden can be moored within a distance of 20 yards. The narrow entrance of Port Jackson—through what is called the 'Heads'—might easily be made inaccessible to any hostile fleet; whilst the central position of S. makes it necessarily the permanent emporium of the greater number of the British dependencies in the southern hemisphere. The immense coal formation of East Australia extends north and south for some 500 miles, with a breadth of from 80 to 100 miles. S. stands nearly in the center of this great carboniferous basin; and at various points within a radius of from 30 to 100 miles, large quantities of coal are raised for colonial consumption as well as for export. The sandstone rock upon which the city is erected affords a valuable material for building.

Since the abolition of transportation, the growth of S. has been rapid, the pop. in 1862 amounting to 93,596, and in 1881 to 220,427, including the suburbs. For many years, S. enjoyed a monopoly of the commerce of these antipodean regions. It has now formidable rivals in Melbourne, Adelaide, and the settlements of Queensland. It must, however, continue the exclusive outlet for the productions and commerce of extensive pastoral and mineral districts on the north-west, west, and south-west. The eastern shore of Darling Harbor has its frontage entirely occupied with wharves and quays.

The streets in the older parts of the town are narrow and irregular: in the newer portions, care has been taken to avoid these defects; and several of the modern streets, from their breadth and the size and style of the buildings, are not behind those of the principal towns of Europe. The shops, warehouses, and private buildings in George and Pitt Streets present long and compact lines of well-built stone edifices, often assuming a very ornate and ambitious style of architecture. The chief thoroughfares are paved, and lighted with gas, and a system of underground drainage has been carried out at a cost of nearly half a million sterling. There is also an abundant supply of pure water, the source of which is a natural reservoir known as the Botany Swamps. There are numerous parks near the city. The Botanical Gardens, the finest in the colonies, cover 38 acres. S. has one shipbuilding establishment. The Fitzroy Dry Dock, originally intended for vessels of the Royal Navy, can take in vessels of the largest size. Lately, steps have been taken to put the city in a state of defence, and forts and batteries armed with powerful Armstrong guns have been erected. The *climate* of S. is, upon the whole, temperate and healthy.

Amongst public buildings, by far the most important edifice, not only in S., but in the whole of the Australian settlements, is the university, which stands on a commanding height, and in the center of a domain of about 150 acres. The principal façade is 500 feet in length, and is flanked at its western end by the Great Hall, the proportions of which are such that were it in England, it would rank as the third in point of size. Lectures are delivered daily during each term on classics, logic, history, chemistry, natural and experimental philosophy, and jurisprudence. The Museum contains a collection of Greek, Roman, and Egyptian antiquities presented by the former chancellor, Sir C. Nicholson. There are two suffragan colleges in connection with the university—that of St. Paul's, belonging to the Church of England; and St. John's, erected under the auspices of the Roman Catholic community. The university, erected out of public funds, has a permanent endowment of £5000 a year from the Civil List; and each of the suffragan colleges receives aid towards its building fund, and the stipend of the warden and rector. Eighteen free scholarships, of the annual value of £50 each, are established in the university, in addition to several others that have been founded by private benefactors. The university is incorporated under an act of the Colonial Legislature and by royal charter. It is only empowered, however, to confer degrees in arts, law, and medicine; and, so far as the university is concerned, instruction is limited to purely secular teaching. The religious training of the pupils is left to the affiliated colleges. The metropolitan cathedral of St. Andrew is a handsome building in the later perpendicular style of architecture. Many of the churches, upwards of 120 in number, belonging to different religious denominations, are tastefully designed.

Amongst the buildings devoted to secular purposes, the most imposing and effective, in point of size and architectural design, are the residence of the governor, the museum, the exchange, the custom-house, the town-hall, the new post-office, and the public grammar-school. The neighborhood of S., with every nook in the adjacent bays, is studded with elegant villas and snug cottages, surrounded by their park-like grounds, and gardens of orange-trees, bananas, and numberless semi-tropical plants unfamiliar to the English eye of the newly-arrived immigrant. There are numerous manufactories; one with 350 hands makes boots and shoes, and 32 make clothing, one steam joinery employs 250 hands. S. has three theaters, several mechanics' institutes, a large hospital for the sick, an orphan asylum, and other charitable and benevolent institutions. In 1878, 1242 vessels, of an aggregate tonnage of 712,303 tons, entered Port Jackson. In 1879, S. successfully carried out its International Exhibition on a large scale.

SYE'NE. See ASSOUAN.

SY'ENITE, a granitic rock found near the city of Syene, in Egypt. It is composed of quartz, felspar, and hornblende, and differs from true granite in having the mica replaced by hornblende. The felspar is generally red (sometimes it is found of a white color), and the hornblende gives a mottled red and dark green color to the rock.

SY'LLABUB, a culinary preparation, formerly much more used than at present. It consists of sugar and cream flavored with brandy, sherry, and lemon rind and juice, worked into a froth, and served up in that state in glasses.

SY'LLOGISM, a name expressing a principal branch or department of Logic. When we reason, or get at truth by means of inference, we are said to proceed either inductively (see INDUCTION) or deductively. Deductive reasoning, when fully and methodically expressed, takes the form called the syllogism. 'This thing will sink in water, for it is a stone,' is a deductive argument, but not fully stated; the complete form is: 'Stones sink in water; this is a stone; therefore this will sink in water'—which form is called a syllogism.

To a perfect syllogism it is necessary that there should be three, and no more than three, *propositions* (see PROPOSITION); these are the conclusion, or the matter to be proved, and two others that are the means of proving it, called the premises. It is also necessary that there should be three, and no more than three, *terms*, namely, the subject and the predicate of the conclusion, and one, called the middle term, which must occur in both premises, being the connecting link for bringing the two other terms together in the conclusion. The *predicate* of the conclusion is called the major term, because it is in its scope the largest of the three; the *subject*

of the conclusion is the minor term, as being the smallest in scope. The three terms enter into the premises in this manner: the major term and middle term make one premise, called the major premise; the middle term and the minor term make the minor premise. In the syllogism above stated, the terms are, 'a thing that will sink in water' (major), 'this thing' (minor), 'stone' (middle); the premises are, 'stones sink in water' (major), 'this thing is a stone' (minor); the conclusion is, 'this thing will sink in water.'

The form now given, although the regular and fundamental form to prove any affirmative conclusion, is not the only form that an argument may assume. The totality of syllogistic forms is divided into *figures*, and each figure into *moods*, which are the distinct syllogistic forms; the principal of division being as follows. The figure is determined by the position of the middle term; which may be the *subject* of the major premise, and the *predicate* of the minor (1st figure), the *predicate* in both (2d figure), the *subject* in both (3d figure), the *predicate* of the major and the *subject* of the minor (4th figure).

The word 'figure' is borrowed from rhetoric, where it means a departure from plain and ordinary speaking, as metaphor, hyperbole, &c. But, as remarked by Hamilton, only the last three of the foregoing enumeration should be called 'figures.' The first should be considered as embracing the regular forms of reasoning, and the others as properly figures—that is, forms more or less inverted, irregular, or unnatural, although still correctly representing reasonings that actually occur. These forms may be all *reduced* to forms in the 1st figure; their inversions or distortions being, as Hamilton would say, *redressed*, or restored to the primitive and fundamental type, namely, the syllogisms of the 1st figure.

The 4th figure did not belong to the original scheme of Aristotle, and it is usually considered as both unnatural and unnecessary, being only an awkward inversion of the first. There would then be the natural or standard syllogisms (the 1st fig.), and two sets of figurative departures from them (2d and 3d figs.).

The syllogisms of each figure are said to differ in *mood*, or according to the *quality* and the *quantity* of the propositions—that is, according as these are affirmative or negative (quality), universal or particular (quantity).

The entire scheme may be presented as follows: The symbols used are P (predicate of conclusion), major term; S (subject of conclusion), minor term; M, middle term. The general type of the first figure or standard is:

M is P.
S is M.
S is P.

When the quality and the quantity of the propositions are expressed, there arise four syllogisms of this form—two affirmative, and two negative:

All M are P.
All (or some) S are M.
All (or some) S are P. } *Barbara, Darii.*

All matter gravitates.
All (or some) air is matter.
All (or some) air gravitates.

No M is P.
All (or some) S is M.
No S is P; some S is not P. } *Celarent* and *Ferio.*

No matter is destructible.
All (or some) air is matter.
No air is destructible; some air is not destructible.

The general scheme of the *2d figure* is:

P is M.
S is M.
S is P.

There are four syllogisms in all, which we may take in pairs thus:

No P is M.
All (or some) S are M.
No S is P; some S are not P. } *Cesare* and *Festino.*

'No destructible thing is matter,' &c., as in the last form.

All P is M.
No S is M; some S is not M.
No S is P; some S is not P. } *Camestres* and *Baroko.*

In this figure, there is a certain distortion of the previous or regular figure. In the first of the two pairs, the major is, No P is M, instead of the equivalent 1st figure), No M is P. In the first form of the second pair, the minor is, No S is M, instead of the equivalent, No M is S, which should be the major to be regular; the amended premises would then give, in conclusion, No P is S, equal to No S is P.

All matter is extended.
No mind is extended.
No mind is matter. } *Camestres.*

The last form, with a particular conclusion, is exemplified thus:

All matter is extended.
Some things are not extended.
Some things are not matter.

This is a form technically called *Baroko*, which is one of two that are especially difficult to reduce to the standard forms.

This figure proves only negatives.

The scheme of premises in the *3d figure* is

M. P.
M. S.

Six varieties of syllogism come under this figure; we may arrange them in three pairs, the first two pairs having the same major, and the third the same minor:

All M is P.
All (or some) M is S.
Some S is P. } *Darapti* and *Datisi.*

All planets move.
All (or some) planets are heavenly bodies.
Some heavenly bodies move.

No M is P.
All (or some) M is S.
Some S is not P. } *Felapton* and *Ferison.*

No solid body is perfectly transparent.
All solid bodies gravitate.
Some gravitating things are not perfectly transparent.

Some M is P; some M is not P.
All M is S.
Some S is P; some S is not P. } *Disamis* and *Bokardo.*

The first of the two is merely a standard syllogism (Darii), with transposed premises; the second (Bokardo) is more complicated, as in the example:

Some men are not fit to rule.
But all men are liable to have dominion.
Some men, liable to have dominion, are not fit to rule.

In the *4th figure*,

P is M,
M is S,

there are five syllogisms. The mere forms are enough to quote.

All P are M.
All M are S.
Some S are P. } *Bramantip.*

All P are M.
No M is S.
No S is P. } *Camenes.*

Some P are M.
All M are S.
Some S are P. } *Dimaris.*

No P is M.
All M are S.
Some S are not P. } *Fesapo.*

No P is M.
Some M are S.
Some S are not P. } *Fresison.*

The reasons why these syllogisms are true, and why no other of 256 possible combinations of propositions can give true conclusions, are certain laws, called the rules of the syllogism, which repose on first principles of the highest certainty.

Mr. Mill has laid down the following fundamental axioms of the syllogism, as stated in its standard forms in the 1st figure. (1.) 'Attributes coinciding with the same attribute, coincide with one another.' M, the middle term, coincides with P, the predicate; S, the subject, coincides with M; therefore S and P coincide with one another. (2.) 'Any attribute incompatible with a second attribute, is incompatible with whatever that second attribute coincides with.' No M is P; M. is incompatible with P; but S coincides with M, and therefore it also is incompatible with P.

All the syllogisms of the last three figures are reducible to the first, by conversion of propositions and transposition of premises, according to the nature of the case. The symbolic name of each syllogism contains instruction for this process, as well as stating the composition of the syllogism. To aid the memory, these symbols are put together in five Latin hexameter verses of very ancient but unknown origin:

'Barbara, Celarent, Darii, Ferioque prioris.
Cesare, Camestres, Festino, Baroko, secundæ.
Tertia Darapti, Disamis, Datisi, Felapton,
Bokardo, Ferison habet, quarta insuper addit
Bramantip, Camenes, Dimaris, Fesapo, Fresison.'

The first line gives the standard figure, and states the propositions entering into each syllogism. The three A's in Barbara are three universal propositions. The E, A, E, in Celarent, are a universal negative, a universal affirmative, a universal negative; in Darii, A, I, I, a universal affirmative and two particular affirmatives, &c. In the other figures the commencing letter (C, B, &c.) shows which standard syllogism each is to be reduced to (Baroko to Barbara, Cesare to Celarent, &c.). The consonant *s* means simple conversion of the proposition marked by the preceding vowel; *p* means conversion by limitation, or *per accidens;* *m* signifies the transposition of the premises; *k* occurs in Baroko and Bokardo, and denotes that these are to be reduced by supposing the conclusion false, and then showing that on that supposition Barbara would be contradicted—from which it is inferred that the original form is true.

There are some species of deductive arguments that do not fall under the syllogistic figures. Thus, the major may state a conditional proposition, and the minor affirm the truth of the condition. 'If the witness is to be believed, the man is guilty' (major); now 'the witness is to be believed' (minor); therefore 'the man is guilty.' A true conclusion would also be obtained by a minor denying the consequent, 'the man is not guilty.' It would then follow that the witness (who affirms his guilt) is not to be believed. But no conclusion would follow from either denying the condition, 'the witness is not to be believed,' or affirming the consequent, 'the man is guilty;' for, in the first place, the man might be guilty whether this particular witness be credible or not; and secondly, the guilt of the man does not prove the credibility of the witness. This is called the *Conditional* Syllogism.

Again, the major may be what is called a Disjunctive or Alternative Proposition, from which also inferences may be drawn by supplying certain minors. 'This was done by either A or B;' now 'it was not done by A (or by B);' therefore 'it was done by B (or by A).' Should the major be understood to mean that it was done by one, and not by both, there would be two other possible inferences. 'It was done by A (or by B);' therefore 'it was not done by B (or by A).' There are other disjunctive pairs, as for example: 'Either A is B, or C is D;' now 'A is not B, therefore C is D,' &c. This is called the *Disjunctive* Syllogism.

A combination of the Conditional and the Disjunctive makes the *Dilemma*. For example:

> If A exist, then either B or C exists.
> Neither B nor C exists.
> Therefore A does not exist.

The following dilemma was given to refute the practice of torturing witnesses: 'A person able to endure pain will be likely to utter falsehood under torture; one unable will be equally likely; therefore, a person under torture will be likely to utter falsehood.'

A very great enlargement has been given to the doctrine of the syllogism, by Sir W. Hamilton (see QUANTIFICATION), Professor De Morgan, and the late Professor Boole of Cork. They have shown that many more syllogistic pairs can be created, and have invented symbols for the purpose. It is, however, comparatively few, either of the old pairs or of the new, that are assumed by the ordinarily occurring arguments, either in the sciences or in common affairs. By far the most useful part of the syllogism is contained within the limits of the 1st or standard figure, which shows what premises are to be looked out for to prove any conclusion: namely, some *general assertion* of matter of fact, affirmative or negative (major), and a *particular assertion* that a given thing comes under the subject of the general assertion (minor), and therefore falls likewise under its predicate. When an argument is stated in a puzzling or perplexed form, with perhaps the omission of one of its essential propositions, it is well to know how to supply the suppressed premises, and put the argument into regular order: the truth or fallacy of the reasoning then becomes evident at a glance.

SYLPHS, in the fantastic system of the Paracelsists, are the elemental spirits of the air, who like the other Elemental Spirits (q. v.), hold an intermediate place between immaterial and material beings. They eat, drink, speak, move about, beget children, and are subject to infirmities like men; but, on the other hand, they resemble spirits in being more nimble and swift in their motions, while their bodies are more diaphanous than those of the human race. They also surpass the latter in their knowledge, both of the present and the future, but have no soul; and when they die, nothing is left. In form they are ruder, taller, and stronger than men; but stand nearest to them of all the elemental spirits, in consequence of which they occasionally hold intercourse with human creatures, being especially fond of children, and of simple harmless people; they even marry with our race, like the Undines and the Gnomes, and the children of such a union have souls, and belong to the human race.

In common usage, the term sylph has a feminine signification, and is applied to a graceful maiden. How this curious change of meaning occurred, is not quite certain; but it is probably owing to the popularity of Pope's *Rape of the Lock*, which introduced the term into the world of fashion and literature. For although even in Pope, the sylph that guards Belinda is a *he*, yet the poet so refined and etherealized his spiritual agents, that they soon came to be associated with all our ideas of feminine grace and beauty; and this circumstance may have reacted on the popular idea—always loose and inaccurate—of their character and sex, and brought about the change of gender to which we have alluded. See Paracelsus's *Liber de Nymphis, Sylphis, Pygmæis et Salamandris et Cæteris Spiritibus* (Basel ed. of Paracelsus's works, 1590.)

SYLVESTER, the name of two popes, and of a third who was an anti-pope. The pontificate of the first immediately succeeded that of Melchiades in 314, and is memorable for the great council of Nicæa, in which the heresy of Arius was condemned. S. himself did not attend the council, but sent two priests—Vitus and Vincentius—to take his place. His name is also celebrated in connection with the so-called donation of Constantine to the Roman Church, the spuriousness of which (although no doubt had been raised regarding it during many centuries) has long been admitted by critics. He died in 335.—Sylvester II., one of the most learned of the medieval popes, originally called Gerbert, was born at Aurillac, in Auvergne, early in the 10th century. He was educated in the monastery of his native village; but went early to Spain, where he learned mathematics, and afterwards to Rome. He was appointed abbot of the monastery of Bobbio, where he taught with much distinction and success. At a later period he went to Germany as preceptor of the young Prince Otho, afterwards Otho II.; and ultimately became secretary to the Archbishop of Rheims, and director of the cathedral school, which became eminent under his care. The archbishop having been deposed, S. was elected to the archbishopric; but he was afterwards set aside, the deposition of his predecessor having been declared invalid. In the year 998, however, he was appointed Archbishop of Ravenna, whence he was called to the pontifical throne, in the following year, under the name of Sylvester II. He was a man of rare acquirements for his age. He was an adept in mathematics, and in practical mechanics and astronomy, in which department his attainments acquired for him among his contemporaries the evil reputation of a magician. He is also believed to have been acquainted with Greek, and perhaps with Arabic. Of all his works, which were numerous, his letters (printed by Du Chesne in the *Historians of France*) have attracted most notice from their bearing on the history of an obscure period.

SYLVESTER, JOSHUA, was born in 1563. His life was divided between the somewhat incongruous pursuits of merchandise and poetry, in neither of which did he achieve a distinct success. Of his original works, the human memory retains no trace; but in virtue of the great, though fleeting popularity obtained by his English version of the *Divine Weeks and Works* of Du Bartas, from which Milton is thought to have derived some hints, he lives in literary history as a sort of *nominis umbra*. He led a somewhat wandering life, and died at Middleburg, in Holland, in the year 1618.

SYLVI'ADÆ, a family of birds, of the order *Insessores*, and tribe *Dentirostres*, including a very great number of small species, among which are many of the birds most noted for sweetness of song, whilst something of this power is possessed by almost all the family, so that the name *Warblers* is often used as synonymous with Sylviadæ. The bill is sharp, slender, straight, and rather compressed towards the tip; the wings moderately long; the legs slender. To this family belong the Nightingale, the Blackcap, numerous species known by the name of Warbler, the Redbreast, Redstart, Wheatear, Whitethroat, Stonechat, Whinchat, Golden-crested Wren, Hedge-sparrow, &c. The S. are diffused over all parts of the globe; and some of those found in tropical countries possess considerable musical powers, but are generally as silent during the great heat of the day as during the darkness of night, and are chiefly to be heard early in the morning.

SYMBO'LIC BOOKS, in the language of the church, is a phrase that signifies the same as Creeds and Confessions (q. v.). The name is derived from the Greek *symbolon*, a sign or mark by which anything is known—a creed being the distinctive mark or watchword of a religious community.

SYME, JAMES, was born in 1799, in the county of Fife, and received a thorough education in art and medicine, in the University of Edinburgh. In his 19th year he began his anatomical studies under Liston, who appointed him his demonstrator. From 1825 to 1832, he lectured on Surgery in the Edinburgh school, and, while generously refusing to lecture in opposition to his old master in the Edinburgh Infirmary, he established a hospital at his own expense, where he delivered a clinical course for four years. In 1831, appeared his well known treatise on *The Excision of Diseased Joints;* and in 1832, his *Principles of Surgery*, which has since gone through many editions, and which has

established his reputation as a teacher of the first rank. In 1833, he was elected to the chair of Surgery in the university of Edinburgh, which he filled with the highest distinction. In 1847, he gave up his Edinburgh chair to fill that vacated in London by the death of Liston; but collegiate misunderstandings induced him, after six months, to return to Edinburgh. As an operator, Mr. S. had no superior; as a teacher, he had no equal. His innovations in the practice of his art were characterized by so much ingenuity, controlled by scientific caution, that they were adopted by all really great surgeons. The best of his pupils, who are numerous, and scattered over every quarter of the globe, have been heard to declare that their soundest ideas in surgery are derived from Syme. Besides the works already named, he was the author of valuable treatises on Diseases of the Rectum; on the Pathology and Practice of Surgery; on the Urethra and *Fistula in Perineo;* on Incised Wounds; &c. He died June 26, 1870. See the *Memoir* by Dr. Paterson (1874).

SY'MMACHUS, Q. AURELIUS, a distinguished Roman orator, scholar, and statesman, who flourished towards the close of the 4th c., was educated in Gaul, and after holding several lesser offices, became prefect of Rome (384 A.D.). Seven years later he was raised to the consulship. The date of his death is unknown, but we know that he was alive in 404 A.D. The character of S. is a very fine one. A sincere pagan in an age when classic paganism was almost extinct, he proved in his own person a pattern of its choicest virtues, and manfully, if in vain, strove to regain for it a place of honor in the state. S.'s extant writings consist of ten books of letters (*Epistolarum Libri X.*) and the fragments of nine orations. The former were published after his death by his son, and contain not a little that is valuable in relation to the history of the period; but the style is in general a slavish imitation of Livy. The best editions of the Epistolæ are those of Juretus (Par. 1604) and Scioppius (Mainz, 1608). The fragments of the orations were first discovered by Cardinal Mai in a palimpsest of the Ambrosian Library, and were first published at Milan in 1815; afterwards, with some additions, at Rome in 1823, in *Scriptorum Veterum Nova Collectio.* See Morin's *Etude sur la Vie et les Ecrits de Symmaque Préfet de Rome* (Par. 1847).

SY'MMETRY OF ORGANS. Throughout the animal kingdom, a symmetry of organs very generally prevails in the two sides of the body. This is the case in man and in all the *Vertebrata;* more perfectly, however, in the external than the internal organs, the two sides of the body presenting great diversities in the circulating, digestive, and other systems. Even the external organs, although similar on the two sides, are never perfectly so. On comparing the two hands, for example, the veins of the one will be seen to differ from those of the other. In *Mollusca*, the symmetry of the two sides sometimes exists, and is sometimes entirely lost, the one side remaining undeveloped in the growth of the animal. In the *Articulata*, the symmetry is in general as perfect as in the *Vertebrata*, and in the internal structure even more so. In the *Radiata*, the whole type is very different, and a very different kind of symmetry appears, not with reference to two sides, but to the rays into which the body divides.

In the vegetable kingdom, a symmetry is found, more or less perfect, but never completely so, between the two sides of leaves, fronds, &c. In flowers, a symmetry appears in the regular distribution of sepals, petals, stamens, &c., around the center of the flower; and even those flowers which least exhibit it when fully blown, as papilionaceous flowers, possess it in the early stages of the bud as perfectly as others.

SYMPATHE'TIC INK. See INK.

SY'MPATHY (Gr. *sympatheia*, fellow-feeling) may be defined as the assumption by different individuals, or by different parts of the same individual, of the same or an analogous physiological or pathological state at the same time or in rapid succession. The late Dr. Todd (art. 'Sympathy' in the *Cyclopædia of Anatomy and Physiology*) divides all the examples of sympathy which are included in the above definition into three classes; first, sympathies between different individuals; secondly, those which affect the mind, and, through it, the body; and, thirdly, those which are strictly organic, and therefore physical.

As examples of the *first class* may be mentioned the readiness with which the act of yawning is induced in a company, if a single person begins to yawn; the facility with which hysterical convulsions are induced in a female hospital ward by a single case; the fascination of its prey by the serpent, apparently by the power of the eyes; the similar power exerted by so-called electro-biologists and mesmerists, and by which some men can control even the fiercest carnivora. Of these sympathies the only explanation that can be given is that suggested in the article on ANIMAL MAGNETISM (q. v.).

As examples of the *second class*, the following cases may be adduced. Certain odors—as of strawberries, mutton, cats, and other most diverse objects—will induce fainting in some people; the smell of a savory dish will excite a flow of saliva in the mouth of a hungry person; and the excitement of the emotions of pity will produce a copious flow of tears. In these cases, an affection of the mind is a necessary link, but why that affection of the mind should produce its peculiar effect, is a question not easily answered; but it is plain that the portion of the nervous center which is affected in such cases, must have a direct influence upon the parts in which the sympathetic phenomena appear, through commissural (or connecting) fibres, or the continuity of its gray matter with that of the center from which its nerves immediately spring. Examples of the *third class* occur in the pain in the knee which arises from disease of the hip-joint; the pain in the right shoulder from disease of the liver; the pain over the brow on taking a draught of iced water into the stomach; the various spasmodic affections connected with intestinal irritation, or the irritation of teething; the vomiting that occurs on the passage of a biliary or renal calculus, &c. All these cases may be more or less satisfactorily explained by the known laws of the sensory and motor nerves. In some of these cases the explanation, however, cannot be regarded as altogether complete. For example, the pain over the brow from the ingestion of cold water or ice into the stomach, may be referred to irritation of the gastric branches of the pneumo-gastric nerves communicated in the medulla oblongata to the fifth nerve; but why the irritation should be confined to the frontal branch of the first (or ophthalmic) division of the fifth nerve, we are utterly unable to explain.

SY'MPHONY, in Music, a word used in two different senses: 1. The instrumental introduction and termination of a vocal composition, sometimes called *ritornello;* 2. A composition for a full orchestra, consisting of from three to six movements. It is for the orchestra what a Sonata (q. v.) is for a single instrument; but generally of greater length, and its movements more fully and richly developed, the subjects introduced being worked out in broader masses. The most usual though not unvarying order of movements is a brilliant allegro, ushered in by a slow introduction, an adagio or andante, a minuet with its trio, a short sportive movement called a scherzo, and a lively finale. The symphony is one of the highest of musical compositions, and one in which excellence is rare. Haydn, Mozart, Beethoven, and Mendelssohn are among the few successful composers of symphony; and the nine symphonies of Beethoven are generally acknowledged to be the greatest works of their class. The Overture (q. v.) is in form not unlike a symphony, but much shorter; but the terms symphony and overture were at one time used almost synonymously, and several of Haydn's early symphonies are called overtures. At the present day the overture in the composer's score of an Italian opera is called *Sinfonia*.

SY'MPHYTUM. See COMFREY.

SY'MPTOMS (Gr. *sympiptein*, to concur), in Medicine, are the morbid phenomena by which the physician becomes aware that derangements of some kind have taken place in the economy; but it requires a mental effort to convert these symptoms into signs of disease. A symptom thus converted into a sign of some special disease or disordered condition, tends to constitute the *diagnosis*, or recognition of the disease. 'The interpretation of symptoms,' as Dr. Aitken observes, 'can only be successful after a close observation of the patient—often prolonged and repeated for more complete investigation—so as to connect the results arrived at with his previous history. The utmost logical acumen is required for the due interpretation of symptoms. The individual value of each ought to be duly weighed; one symptom must be compared with another, and each with all, while the liability to variation of a similar symptom in different cases of a like kind must not be forgotten. Thus only can the nature of a disease be clearly determined, its severity and dangers fully appreciated, its treatment indicated, and the probability of recovery foretold.'—*The Science and Practice of Medicine*, 3d ed., vol. i., p. 9. Many writers, following the example of Laennec, confine the term *symptom* to the phenomena depending on vital properties; while those phenomena of disease which are more directly physical, they call *signs*. We thus have what may be called *physical signs* and *vital symptoms*. The form, size, color, firmness or softness, heat and odor of a part of the body, the sounds which it yields on percussion or discultation, &c., afford *physical signs;* while *vital symptoms* may be exemplified in pain, uneasiness, altered or impaired sensations, spasm, vomiting, the accelerated pulse and hot skin of fever, the state of the tongue and of the alvine and urinary excretions, &c. The term *semeiology* (literally, *the theory of signs*) has been given by medical writers to the general study of this subject, which is admirably discussed in Williams's *Principles of Medicine*.

SY'NAGOGUE (Gr. = *ecclesia;* Heb. *beth-hakke-neseth*, house of assembly), a Jewish place of worship. The origin of this institution is probably to be traced to the period of the Babylonian captivity, although tradition finds it in the patriarchal times. When, at the time of Ezra, and chiefly through Ezra's instrumentality, the ancient order of things was re-established in Judea, synagogues were established in all the towns for the benefit

of those who could not take part oftener than three times a year, or not even as often as that, in the worship of the temple at Jerusalem, and a special ritual of lectures and prayers was instituted. From the time of the Maccabees, we find them even in all the villages; and Josephus, Philo, the New Testament, the Mishna, and the Talmud, constantly allude to them. Common prayer and religious instruction were the purpose for which the people there met. The Sabbaths and feast-days were the principal times on which the faithful assembled in them; and they contributed more than anything else to the steadfast adherence of the people to their religion and liberty as long as there was any possibility of keeping both intact. At the same time, they gradually undermined the priestly and aristocratic element that gathered round the temple, its gorgeous worship and kingly revenues. Little is known of any special laws respecting the construction of these buildings, save that the faces of the worshipers should be directed towards Jerusalem (*misrach* = eastwards) (see MOSQUE); or that, in accordance with a verse in the Psalms, there should be a slight descent of a step or two on entering it, or that it should stand, if feasible, on a slightly elevated ground, or be somehow or other made visible far off.

Erected out of the common funds or free gifts of the community, it had also to be supported by taxes and donations. All profane doings were strictly prohibited in it. No eating, drinking, reckoning, and the like, were allowed; and even as to dress and other things of general decorum, the reverence due to the place was enforced as rigidly as possible. It represented in miniature the form of the temple, itself an enlarged type of the tabernacle. At the extreme eastern end was the *Aron hakkodesh*, the holy ark, containing several copies of the Pentateuch, from which the periodical readings were chanted. In front of this was the stand of the public reader of the prayers, not far from which was suspended the everlasting lamp (*ner tamid*). On a raised platform in the middle of the synagogue, was the place of the reader or preacher. The women sat separated from the men by a low partition five or six feet high. The affairs of the synagogue were administered by a board of 'ancients' or 'elders,' at whose head stood a chief or principal (*Rosh hakkeneseth=archisynagogos*). This college managed the inner affairs of the synagogue, and had even the power of excommunication. The officiating minister, whose office it was to recite the prayers aloud, was called *sheliach tzibbur*—messenger of the community (*angelos ecclesias*, Rev.). His qualifications, were, among others, to be active, to be father of a family, not to be rich or engaged in business, to possess a good voice, to be apt to teach, &c.

The beadle, or *chazzan*, had the general charge of the sacred place, and its books and implements. He had to present the scroll to the reader, and assist on other occasions. During the week-days, he had to teach the children of the town or village. He too had to be initiated by a solemn imposition of hands. This name of chazzan, however, at a later period, came to designate the officiating minister, and it has retained that meaning until this day. Almoners or deacons, who collected and distributed the alms, possibly the same as the *Batlanim* or 'idle men,' whose office in relation to the synagogue cannot be exactly determined now, but who had always to be ready for the purpose of making up the requisite number of *ten* worshipers, were further attached to the general body of officials. Respecting the prayers used, we have spoken under LITURGY (JEWISH). As to the time of daily worship, we may observe that the third, sixth, and ninth hours of the day were the times appointed for it, and the more special days were the Monday and Thursday, when the judges sat, and the villagers came to town; and the Saturday, on which the forms of some of the prayers were altered according to the occasion.

On the connection between the Jewish synagogue and the Christian church, and their respective rites and modes of worship, we cannot here enlarge. Thus much, however, we may say, that it is obvious to the most superficial observation that the principal practices of the latter belong, with certain modifications, to the former; and it has been conjectured that even the melodies of certain hymns still sung in the Roman churches are to be traced to the temple and the synagogues. It is, moreover, well known that the early Christian churches were entirely organized after the pattern of the synagogues. As to the judicial power exercised by the officers of the synagogue, we refer to SANHEDRIM. They had, there can hardly be a doubt, a kind of authority with regard to religious transgressions; but how far they were allowed to carry this authority, is not so easily determined. Modern synagogues differ but in some minor points—additional prayers and the like—from what we gather to have been the nature of those at the time of Christ, save that there are no more elders, but a simple board elected from the community, without any authority beyond that of, perhaps, a board of churchwardens, and that the chazzan, as we said, has now the functions of the 'sheliach.' See JEWS, JEWISH SECTS, LITURGY (JEWISH), &c. The languages used in the early synagogues of Palestine and Alexandria, were Hebrew, Aramaic, and Greek respectively.

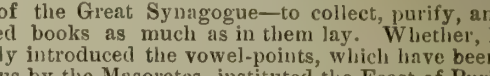
SY'NAGOGUE, THE GREAT (*keneseth haggedolah*), an assembly or synod, supposed to have been founded and presided over by Ezra, consisting of 120 men, said to have been engaged in remodelling the national and religious institutions of the Jews after the return from Babylon. The palpable chronological discrepancies that occur in the early accounts about this synod, together with other doubtful points, have led modern scholars to deny its existence completely. But the fact of Josephus not mentioning it avails very little against the positive assertions of the Talmud, and what is still more important, of the Karaites, the professed adversaries of all tradition. True, Ezra, the contemporary of Artaxerxes, can never have taken his place in it together with Zerubbabel and Joshua, who left Babylon under Cyrus, or with Simeon the Just, who lived at the time of Alexander the Great. These, however, are but apparent anachronisms. The tradition never meant anything else than that the institution founded by Ezra, and which lasted up to the time of Alexander, comprised 120 men, of whom Simeon was one of the last. Anyhow, there is absolutely no reason to doubt that Ezra and Nehemiah did a certain amount of work which they could not have done without being assisted by eminent collaborators. It was this body to which certain vital ameliorations in the administration of justice are ascribed.

They developed public instruction, and fixed and enlarged the Mosaic laws by certain rules of interpretation. 'Be circumspect in judgment; make many disciples; and erect a fence around the law;' are some of the principal sayings ascribed to them. Above all, it seems to have been the office of Erza and his coadjutors—the men of the Great Synagogue—to collect, purify, and redact the sacred books as much as in them lay. Whether, however, they really introduced the vowel-points, which have been handed down to us by the Masoretes, instituted the Feast of Purim, sanctioned the Eighteen Benedictions (see LITURGY, JEWISH), &c., is more than doubtful. They certainly disappeared before the Sanhedrim (q. v.) were instituted, but it may be that their legislative functions were no longer needed at that advanced period.

SYNA'NTHERÆ. See COMPOSITÆ.

SYNCLI'NAL AXIS is the line of curve in the trough of a series of beds from which the strata rise on either side. The ridge-curve is called the anteclinal axis.

SYNCOPA'TION, in Music. Notes which begin on the unaccented part of a measure, and end on the accented, are called syncopated or driving notes. Their effect is to invert the rhythm, and lay an emphasis on the usually unaccented part of the measure, e. g.:



SY'NCOPÉ. See FAINTING.

SY'NDIC (Gr. *syn*, with, and *diké*, justice), a name which has at different times and in different countries been given to various municipal and other officers. In Geneva, the chief magistrate was formerly called the syndic. The syndics of cities in France, under the old régime, were officers delegated by the municipality as agents or mandatories; the various trading companies in Paris and the university had also their syndics; and in the university of Cambridge the same name is applied to members of special committees of members of the senate, appointed by grace from time to time for specific duties. See UNIVERSITY.

SYNE'CDOCHÉ (Gr. literally an 'understanding one thing with another') is a term in rhetoric denoting that mode of expression by which a part is put for the whole, and *vice versâ*; as e. g., a door for a house, a sword for any weapon of war.

SYNE'RGISM (Gr. *synergeo*, to work together with), the name given to a doctrine of theology which teaches that in the work of conversion, the will of man is not wholly passive, but can co-operate, through consent, with the Divine Spirit. About 1557, the question was hotly discussed by the Protestant theologians, Pfeffinger, Flacius, and Strigel, and soon the whole theological world was wrangling over the point. The Wittenberg divines were in favor of, the Mansfield divines against, synergism. Finally, the *Concordien formel*, in its third article, condemned it.

SYNGE'NESIA. See COMPOSITÆ.

SYNGNA'THIDÆ. See PIPE-FISH.

SY'NOD (Gr. and Lat., an assemby) in general signifies a meeting, but it is almost exclusively applied to ecclesiastical assemblies for the purpose of deliberating on doctrinal or disciplinary subjects. In church law, several kinds of synods—called also Councils (q. v.)—are enumerated: (1) ecumenical or general, of the entire church; (2) national—that is, of the church of an entire nation; (3) provincial—that is, of a province; (4) diocesan, or of a single diocese. Of these, the ecumenical council has been

already described. Of the others, little explanation is needed beyond what is conveyed in the names themselves. By the law of the Roman Catholic Church, the decrees of a national or provincial synod must be submitted to the pope, and unless confirmed by him, or at least suffered to pass for two years without condemnation, are not held to have force. The diocesan synod is convened by the bishop, and consists of the members of the chapter, the beneficed clergy having the permanent care of souls, and the heads of the communities of regular clergy. Synods of the English Church are only held by the authority of the crown. A Presbyterian synod consists of only the ministers and elders within the particular district, generally one elder for each congregation. It is subordinate, however, to the General Assembly, when there is a General Assembly.

SYNO'DIC, the epithet applied to the period which elapses between a planet's appearance at one of the nodes of its orbit, and its return to the same node. See NODES and MONTH.

SY'NONYM. When any one of the several words will serve to name or express the same thing, that thing is said to be *polyonymous*, or many named, and the words are called *synonyms* (Gr. names together, or in company). In this wide sense, *man, soldier, general, Frenchman*, might be called synonyms, as they can all be applied to denote the same individual—e. g., Napoleon. See NOUN. But the term is commonly applied in a restricted sense to words having substantially the same meaning, with only slight shades of difference—as *observe* and *remark*. In a settled and matured language, no two words can have exactly the same meaning; in such a case, one of them would be superfluous, and would be silently dropped. Words that were originally identical in application, have become differentiated by usage, each being appropriated to a special variety of the general notion.

The English language abounds in pairs of synonyms like *sharp* and *acute*, of which the one is Anglo-Saxon, the other borrowed from the Latin. It would be difficult to find a case of more exact correspondence of sense than *acutus* in Latin, and *sharp* (Ger. *scharf*) in Teutonic; but *acute* in English has become confined to the metaphorical sense of sharpness of the intellect or of the senses, the only case of its retaining the primary, physical signification being in the technical phrase, an 'acute angle.' *Sharp*, again, is applied both in the physical sense and also in the metaphorical; but metaphorical *sharpness* is not exactly the same thing as *acuteness*. A 'sharp' lad is one quick in apprehension and movement; an 'acute' intellect is one having great power of penetration and discrimination; while in a lawyer of 'sharp' practice, a reprehensible moral quality is implied.

SYNO'VIAL MEMBRANES AND FLUID. In every joint in which a considerable range of motion is required, the osseous segments (or contiguous extremities of bones) are separated by a space, which is called the cavity of the joint. The end of each of the bones entering into the composition of the joint is incrusted by a layer of articular cartilage adapted to its form, and the entire cavity of the joint is lined by a delicate membrane, which is termed the *synovial membrane*, which secretes a peculiar viscid matter, termed *synovia*, or *synovial fluid*, for the purpose of lubricating the inner surface. In its microscopical characters, a synovial membrane so closely resembles a serous membrane, that we shall content ourselves with referring the reader to the article on the latter structures. There are, however, certain points of difference, which are fully described in the article 'Serous and Synovial Membranes' in *The Cyclopædia of Anatomy and Physiology*. Like a serous membrane, a synovial membrane is always a closed bag, like the pleuræ, for example, with an attached and a free surface, the latter being smooth and moist. A very simple form of synovial membrane—anatomically known as a *bursa*—is employed to facilitate the gliding of a tendon of a muscle or of the integument over a projection of bone. It consists of a bag connected by areolar tissue with the neighboring parts, and secreting a fluid in its interior. These bags are sometimes prolonged into *synovial sheaths*, which surround long tendons, such as those of the flexor and extensor muscles of the fingers and toes. In deep-seated Whitlow (q. v.), when inflammation extends to one of the sheaths, and gives rise to the formation of adhesions, the motion of the enclosed tendon is destroyed, and a permanently stiff finger is the result.

The *synovial fluid*, or *synovia*, derives its name from its resemblance to the white of an egg (Gr. *syn*, with, and *oön*, an egg). It consists of water, holding in solution mucin, albumen, extractive matters, fat, and inorganic salts. The analyses of Frerichs show that the composition and quality of the synovia vary essentially according as an animal is at rest or leads a wandering life.

SY'NTAX (Gr. *taxis*, arrangement, *syn*, together) is the part of grammar that teaches the putting together of words for the expressing of thoughts; in other words, it treats of the construction of sentences. The first step is the analysis of sentences—the study of their anatomy and physiology, as it were (see SENTENCE). This important part of the subject is too often altogether overlooked. A clear perception of the mutual relations of the several members of a sentence makes the usual rules of syntax appear self-evident truths, and in most cases superfluous. Most of these rules fall under the heads of (1) Concord and Government, and (2) Order of Words, or Collocation. For details, we must refer to special works on the subject.

SY'NTHESIS (Gr. *synthesis*, making a whole out of parts) is a term employed in chemistry to designate the building up of a more or less complicated product from its elementary constituents. As the synthesis of inorganic compounds is usually very simple, we shall confine our remarks to organic compounds. To take a very common substance as an illustration, there is no difficulty in resolving sugar into its ultimate elements, or, in other words, in ascertaining its composition by analysis. If we heat a little sugar to redness in a glass tube, it leaves a black deposit, which is carbon, while a liquid, which is water, distils over; and on electrolyzing this liquid, we resolve it into hydrogen and oxygen; so that we can thus show that sugar is composed of the ultimate elements, carbon, hydrogen, and oxygen. An analysis of this kind shows that sugar may be represented by the formula $C_{12}H_{11}O_{11}$, and that one atom, or any given weight of it, contains 72 atoms or parts by weight of carbon, 11 of hydrogen, and 88 of oxygen. This pulling to pieces of the sugar is an easy matter, and has been known to chemists for more than half a century; but the putting together of the pieces, or, in other words, the synthesis of sugar, is a very much more difficult task.

We may bring together carbon, hydrogen, and oxygen in the due proportions, and, to use the words of Professor Wanklyn (in a lecture delivered at the Royal Institution, February 12, 1864), 'we may shake them all together, or heat them, or cool them, and yet we shall never get them to combine so as to form sugar. Alcohol consists of 24 parts of carbon, 6 parts of hydrogen, and 16 parts of oxygen; but no alcohol ever results from making such a mixture. Neither sugar nor alcohol can exist at the temperature to which it is requisite to raise our mixture of carbon, hydrogen, and oxygen, in order to get chemical action to set in. At ordinary temperatures, the organic elements will not enter into combination, whilst at high temperatures they combine, it is true, but yield comparatively very few compounds.' There was a general belief that organic products, such as sugar, alcohol, urea, oxalic acid, taurine, leucine, &c., required for their production a mysterious so-called *vital force*, totally distinct from the ordinary forces acting on matter. The first blow to this now obsolete doctrine was struck by Wöhler in 1828, when he discovered that the organic base *urea* might be artificially obtained. See ORGANIC COMPOUNDS. Three years afterwards, Pelouze obtained *formic acid* from inorganic materials. In 1845, Kolbe, by a somewhat complicated process, effected the synthesis of *acetic acid*, and consequently, indirectly, of its derivatives, amongst which may be enumerated *acetone*, the product of the destructive distillation of acetates; *marsh gas*, obtained by distilling an acetate with a caustic alkali, and *ethylene;* and the electrolysis of acetic acid, which Kolbe accomplished a few years afterwards, yielded methyl and oxide of methyl, which latter could be transformed into any other methylic compound.

During the last twelve years, new and simpler methods have been suggested by various chemists, amongst whom Berthelot must be especially mentioned, and enormous additions have been made to the list of so-called organic compounds which have been synthetically constructed. We shall give a description of the mode of producing alcohol synthetically, and shall then show that from it, as a starting-point, an immense number of other organic compounds can be synthetically produced. To obtain this product synthetically, several distinct steps are necessary. The first is the formation of a transparent colorless gas, acetylene, C_4H_2, from carbon and hydrogen in the electric arc; by passing this gas through sub-chloride of copper, acetylide of copper is produced, which, in contact with nascent hydrogen, gives olefiant gas, C_4H_4; agitated with sulphuric acid, olefiant gas produces sulphovinic acid, $C_4H_5O,2SO_3,HO$ (a discovery due to our own chemists, Faraday and Hennell, in 1820). On distilling this acid diluted with water, dilute alcohol comes over, which, on redistillation, in contact with quick-lime, yields pure *vinic or ordinary alcohol*, $C_4H_6O_2$. Having thus obtained ordinary alcohol from inorganic materials only, we may employ it to form by synthesis an immense number of other organic compounds. By means of what is known as 'the process of Mendius,' we can, as it were, step from one alcohol to the next above it. Thus, from vinic alcohol ($C_4H_6O_2$) we obtain *propylic* (or *tritylic*) *alcohol* ($C_6H_8O_2$); from this we obtain *butylic* (or *tetrylic*) *alcohol* ($C_8H_{10}O_2$); from this, *amylic alcohol* ($C_{10}H_{12}O_2$), and so on.

From the propylic alcohol thus obtained, we get by oxidation *propionic acid*, from which *lactic acid*, the acid of sour-milk, may be obtained; similarly, butylic alcohol yields butyric acid, every alcohol, in short, yielding a corresponding fatty acid by oxidation. *Glycerine*, the base of the fats, may also be obtained by a

somewhat circuitous process. By combining glycerine with propionic acid, and with the other fatty acids which may be synthetically formed, we obtain several oils and fats similar to those which occur as natural products. The case of *taurine*, $C_4H_7NS_2O_6$, is even more striking; it is a product of various glandular metamorphoses, but its chief source is the bile, where it exists in conjugation with cholic acid as tauro-cholic acid. This highly complex substance can readily be formed in the laboratory from sulphuric acid, alcohol, and ammonia, each of which is capable of being built up from its constituent elements.

Sugar has been obtained by Berthelot from glycerine, a substance which is obtainable by purely inorganic means; but as he effected the conversion of the glycerine into sugar by the action of putrefying animal tissue, we can hardly regard the sugar thus formed as being of purely inorganic origin, although the animal tissue only acted catalytically, or as a ferment, and did not contribute any actual material to its formation.

There is, however, no doubt that an unexceptional means of producing this important alimentary substance will soon be devised, since bodies strictly allied to sugar have been already obtained.* Another artificial compound of great interest in an industrial point of view, is *toluol*, $C_{14}H_8$, which has recently been obtained from phenele, which can itself be produced synthetically from alcohol. 'Starting,' says Dr. Odling, 'from these two bodies, we may procure all the so-called coal-tar colors, with the brilliancy and variety of which most of us are now familiar. The red base or rosaniline, $C_{40}H_{19}N_3$, the violet base or triethylrosaniline, $C_{62}H_{31}N_3$, and the blue base or triphenylrosaniline, $C_{76}H_{31}N_3$, being producible in this way from their constituent elements, furnish admirable illustrations of the constructive powers of modern organic chemistry.'

We cannot conclude without adverting briefly to the possibility of economically replacing natural processes by artificial ones in the formation of organic compounds. On this subject, one of our most distinguished organic chemists, Dr. Frankland, observes, that 'at present, the possibility of doing this only attains to probability in the case of rare and exceptional products of animal and vegetable life. By no processes at present known, could we produce sugar, glycerine, or alcohol from their elements at one hundred times their present cost, as obtained through the agency of vitality. But although our present prospects of rivaling vital processes in the economic production of staple organic compounds, such as those constituting the food of man, are exceedingly slight, yet it would be rash to pronounce their ultimate realization impossible. A brilliant triumph of chemical synthesis is the successful production of common indigo from phenylacetic acid, at small cost. The method was announced by its inventor, Prof. Baeyer of Munich, in 1878. (See article in *Nature*, 1878.)

See Berthelot's *Chimie Organique fondée sur la Synthèse* (1860) and his lectures on the *Leçons de Chimie professées en* 1860 *et* 1862; to various lectures by Wanklyn, Frankland, and others, delivered at the Royal Institution; to Odling's lectures *On Animal Chemistry* (1865); and to recent works on organic chemistry, such as the new edition by Armstrong and Groves of Miller's *Elements* (1880), and vol. iii. of Roscoe and Schorlemmer's *Treatise on Chemistry* (1881).

SY'NTONIN, or MUSCLE FIBRIN (Gr. *synteinein*, to render tense), contains in 100 parts: carbon, 54·06; hydrogen, 7·28; nitrogen, 16·05; oxygen, 21·50; and sulphur, 1·11. It is the principal constituent and the essential basis of all the contractile tissues. It may be obtained from muscular fibrin in the form of a coherent, elastic, snow-white mass; but whether it exists in the living body in a solid form or in solution, is undecided. Many recent physiological writers hold the latter view, and maintain that the phenomenon of cadaveric rigidity (*rigor mortis*) is due to its spontaneously coagulating after death.

SY'PHILIS is, according to Dr. Farr's system of nosological classification, to be regarded as belonging to the enthetic order of zymotic diseases (see NOSOLOGY and ZYMOTIC DISEASES.) These diseases have the common property of being developed in the system after the introduction by inoculation or implantation of specific poisons. The poisons which produce diseases of this order may be introduced through any abraded cutaneous surface, or through mucous membranes, especially if any solution of continuity occurs. A morbid poison thus introduced into the system produces a specific effect both on the tissue at the place of insertion and on the blood, as soon as the poison begins to become absorbed; or, in other words, it produces both a constitutional and a local change. The absorbed virus seems to undergo the following changes in the living and infected body—viz. (1) Increase, (2) Transformation, and (3) Separation or Excretion.

Taking our illustrations from the disease to which this article is specially devoted, the *increase* is shown by the fact, that the pus from a single syphilitic sore may by inoculation be made to spread the disease a thousand-fold. The *transformation* is indicated by the successive phenomena which supervene during the course of the disease. For example, syphilis is followed, as we shall presently show, by a series of secondary and tertiary phenomena, which follow a tolerably uniform course in different patients. The *separation* or *excretion* of the poison may be accomplished in several ways. While in some of the more intense poisons—such as those of certain serpents—the whole mass of the blood seems rapidly affected, in others, as syphilis, 'a double process of the zymotic-like action seems to take place before the full effects which the poison is capable of producing are completed. The multiplication of the venereal poison, and its effects upon the system, seem to become developed during the existence of the hardening process which surrounds the infecting venereal sore. This is the first zymotic-like process, and is attended with a local papule, and perhaps an ulcer. From this local sore the system becomes contaminated, and in the blood a second process (of zymosis?) appears to be completed, by which the original poison becomes intensified, its pernicious influence more complete, and its specific, secondary, and tertiary effects are more fully developed.'—Aitken's *Science and Practice of Medicine*, 3d ed., vol. i. p. 666.

From this brief sketch of the nature of enthetic diseases, we turn to the consideration of the special disorder known as *syphilis*—a word whose origin is unknown. The terrible ravages of this disease amongst our soldiers and sailors, to say nothing of the fearful misery which it occasions in private life, afford more than sufficient apology for our introducing into these pages some of the most important details regarding this repulsive form of disease* It is almost unnecessary to observe that syphilis is a contagious disease usually propagated by impure sexual intercourse. The following is a brief history of the course of the disease, if its progress is not checked by proper remedial agents.

At an uncertain period, varying from three to ten days, after exposure to the infection, one or more venereal ulcers (commonly known as *chancres*) appear upon the generative organs. These ulcers present many varieties, which have been variously classified. The following arrangement, by Mr. Henry Lee, Surgeon to the Lock Hospital, is an eminently practical one—viz. (1) The Hunterian or indurated or infecting chancre; (2) The non-indurated or suppurative chancre; (3) The ulcerative chancre; and (4) The sloughing chancre. These local affections are so different in their characters, and in their action on the constitution, that each must have a brief separate notice. (1) The *indurated*, or, as it is frequently termed, the *Hunterian chancre*, from its having been first accurately described by John Hunter, is the only one of these local affections that can be associated with constitutional syphilis. Its natural course is thus described by Mr. Lee. 'At an uncertain period, but generally from three to four days after exposure to infection, attention may be drawn to the part by a slight itching. On examination, a red spot, surrounded by a little induration, will perhaps present itself, or a vesicle about the size of a millet-seed will not unfrequently form upon the infected part. The cuticle covering this vesicle is so thin that it usually gives way at a very early period; and this commonly happens before the disease has been carefully examined. The base of the vesicle then becomes indurated, and the induration (whether preceded or accompanied by a pimple or a vesicle, or independent of either of these) assumes a circular form, extending equally in every direction, and terminating quite abruptly in apparently healthy parts. A sore generally follows; this is excavated, without granulations, sometimes glazed, at other times having some adhesive matter on its surface.

'The color of the chancre will depend often upon the amount and character of the substance which adheres to it, and will frequently present a fawn hue, or different shades of brown and red. When this adventitious matter is removed, the sore will usually again assume its original smooth and red glazed appearance.'—'Syphilis' in Holmes's *System of Surgery*, vol. i. p. 400. This variety of sore frequently gives rise to a chronic enlargement of one of the glands of the groin (forming what is termed a *bubo*),

* Carius, a trustworthy chemist, announced some years ago that he had succeeded in forming *Phenose*, a kind of sugar, and possessing all its chemical characteristics, from benzol.—*Ann. d. Chem. u. Pharm.*, Dec. 1865.

* Dr. Aitken observes that 'no statistical nosology gives any idea of the number of men lost to the public service from syphilis. The loss of strength from venereal diseases alone (gonorrhœa being included with syphilis in this term, and forming about 40 per cent. of the cases) is equal to the loss of more than eight days annually of every soldier in the service.' Dr. Balfour in his *Medical, Sanitary, and Statistical Report of the Army Medical Department* for 1860, relates that 'more than one-third of all the admissions into hospital have been on account of venereal diseases (369 per 1000), and the average number constantly in hospital is equal to 23·69 per 1000 of strength (2315 men), each remaining in hospital on an average 23¼ days. Thus the inefficiency is constantly equal to about 2¼ regiments.' In 1861, these diseases caused a loss equal to 8·69 days for every soldier serving at home, there being a daily inefficiency of 2077 men; and the numbers are nearly the same for the succeeding years. The daily loss of service in the navy, in 1862, was about that of 586 men per day. How far these data apply to our civil population, it is hard to say; but it is much to be feared they apply pretty closely. 'It is a question,' says Dr. Parkes, 'whether a large majority of the young men of the upper and middle class does not suffer in youth from some form of venereal disease. In the lower classes, it is perhaps equally common.'—*Practical Hygiene*, p. 453. For a comparison between the amount of venereal disease in our own and other armies, the reader may consult the same work, pp. 502, 503.

which does not involve the skin or the cellular membrane. It is followed by certain constitutional symptoms known as *secondary symptoms*, and requires, both in its primary and secondary forms, mercurial treatment. (2) The *suppurating chancre* usually begins as an abrasion, which, when fully developed, often presents the same appearance as if a piece of skin had been removed by a circular punch. The sore is covered with ill-formed granulations, and extending equally in all directions, maintains its circular form. After continuing three or four weeks, it generally heals, without leaving the hardness which is so characteristic of the Hunterian, infecting or indurated sore. Another important diagnostic difference is furnished by the microscopico-chemical examination of the fluid secreted by the sore. In this suppurating sore, the secretion consists of pus, which, on the addition of acetic acid, exhibits the characteristic compound nuclei; while in the infecting sore the secretion resembles turbid serum, presenting none of the characters of the pus. It does not give rise to bubo, nor is it followed by secondary symptoms.

(3) The *ulcerative chancre* is a ragged worm-eaten ulceration; secreting an ill-formed pus, and presenting an irritable surface. Soon after the appearance of this sore, one of the glands of the groin will become enlarged and painful. This may be preceded by a shivering fit, more or less marked. The enlarged gland or bubo becomes very tender to pressure, and as the swelling increases, the skin becomes red, especially at the center, and the general symptoms of suppuration present themselves. Great relief is afforded by the discharge of the pus. It is never followed by secondary symptoms, and, like the preceding form, requires only local treatment. (4) The *sloughing chancre* is fortunately rare in this country, but in many foreign ports, in warm and hot countries, this form of syphilis commits great ravages amongst our sailors, who have given to it certain characteristic names, such as the *black-pox*, the *black lion*, &c. It does not affect the inguinal glands, and is not followed by constitutional symptoms, and requires only local treatment.

Before noticing the constitutional or secondary symptoms which follow the Hunterian or infecting sore, we shall very briefly describe the treatment required for the last three forms, in which no constitutional symptoms occur. A suppurating sore should at once be thoroughly cauterized, so as to destroy all the tissues which have imbibed the poison. To secure this result, strong caustics are desirable; and as they sometimes extend further than is desired, an antidote should be at hand, which not only checks the further extension of the caustic, but deadens the pain. The agents most used in these cases are caustics and the mineral acids, and the *potassa cum calce*, a combination of potash and lime, which is prepared in the form of small rods for this purpose. The last of these is on the whole the best, as the extent to which it acts may be accurately regulated. When the action is sufficient, the application of a dilute acid will relieve the pain. Nitrate of silver, which is often employed, is not sufficiently energetic in its action to eradicate the disease. In the ulcerative sore, which is often irritable and painful, opium is useful both locally and internally. In other respects the same treatment must be adopted as in the preceding variety. As the various means that have been suggested for preventing the suppuration of the bubo, which always accompanies this sore, are of no avail, it is useless to mention them. If, after the bubo has burst, the remains of an indolent, enlarged gland, incapable of forming healthy granulations, are left, caustic must be applied, so as to cause them to slough away. In sloughing sores, the great object is to check the destructive process; for which purpose, fomentations and poultices are applied locally, and large and repeated doses of opium are given internally. The nitric acid lotion, or a solution of potassio-tartrate of iron (10 grains to an ounce of water), is often an efficient local application in these cases.

We now return to the consideration of the Hunterian or indurated chancre, the only variety of venereal sore that gives rise to secondary or constitutional symptoms. If the patient seeks medical assistance as soon as he perceives the sore, it is possible that the application of a caustic will destroy the poison, and prevent any constitutional symptoms. If, however, four days or more elapse before treatment commences, the best local application is some form of mercury, as mercurial ointment spread on lint, or the application of black wash (see LOTIONS) steeped in the same material. When the poison has once entered the circulation, and become diffused throughout the body, it is desirable to neutralize it, if possible, before the appearance of any secondary symptoms. A very large number of drugs have at different times possessed an anti-syphilitic reputation, and a few are doubtless useful; as, for example, iodide of potassium. 'There is one medicine alone,' says Mr. Henry Lee, one of the highest British authorities on the subject, 'which, through good report and evil report, in spite of the strongest prejudices of some against its use, and the no less adverse influence of others, who have employed it to an unjustifiable extent, has maintained its general reputation.'—*Op. cit.*, p. 418.

In these remarks on the value of mercury (if judiciously given) we fully concur; but the mercurialists and non-mercurialists are almost equally divided. It may be given internally in pills or in solution; or it may be introduced into the system through the skin, in the form of ointment; or lastly, it may be employed in the form of vapor, and thus applied to the skin. Of these three methods, none is equal to mercurial fumigation by calomel vapor, either in the readiness with which it removes the symptoms, or the slight disturbance it excites in the constitution, or in its certainty in preventing relapse. This process is a very simple one. A piece of brick must be heated to a dull red heat, and placed in a pan having a little water at the bottom. A quantity of calomel, varying from 10 to 20 grains, is placed on the top of the brick; and the patient then sits over the pan in a cane-bottomed chair, enveloped from his neck downwards in a large blanket.* The operation is best performed at bedtime; it is complete in a quarter of an hour; and when the patient is sufficiently cool to put on his night-shirt, he should go to bed without disturbing the calomel on the surface of the skin.

It is almost impossible to produce salivation by this means of administering mercury; and all that is requisite is to produce a slight tenderness of the gums. The system must be kept under this gentle influence of the mercury till the induration in the primary sore has disappeared. At a period usually varying from one to two months after the first appearance of the induration (which is regarded by some writers as the first of the secondary symptoms), slight febrile symptoms, usually followed by an exanthematous eruption of the skin, often accompanied by sore throat, will occur. This eruption is a variety of *roseola;* it is of a rose-red color, which disappears on pressure, and is not raised above the surface. It generally disappears in a few days, but if it persist, it will gradually change to a copper color, which is characteristic of all syphilitic eruptions which remain for a considerable time without suppurating or ulcerating. The syphilitic eruptions which usually follow this primary rash may assume the varied forms of lichen, syphilitic tubercule, lepra, and psoriasis; and the best mode of treating them is by applying local mercurial fumigation, and at the same time giving iodide of potassium (in five-grain doses thrice a day) internally. Occasionally in persons with impaired constitutions, syphilitic eruptions assume a postular character. For a description of these eruptions, we must refer to Cazenave's *Manual of Diseases of the Skin*, translated by Burgess. Similarly, there are cases in which, from some constitutional peculiarity, or, as Mr. Lee suggests, from some want of power in carrying out the natural processes of the disease, the syphilitic eruption may be accompanied by an effusion of serum only; or, in other words, may be of the vesicular type. Thus, we hear of syphilitic herpes, syphilitic eczema, &c. These forms must be treated as the others.

Amongst the secondary syphilitic diseases of the mucous membrane, may be especially noticed (1) mucous tubercles, (2) deep ulcer of the tonsils, and (3) syphilitic laryngitis. *Mucous tubercles* appear as small tense eminences inside the cheeks, on the arches of the palate, on the lips, on the generative organs, and on the rectum. A solution of corrosive sublimate applied locally (one or two grains to the ounce of water), or calomel, proves an effective local application. *Deep ulcer of the tonsils* is best treated by corrosive sublimate given internally, in doses of $\frac{1}{12}$th of a grain three times a day, in compound tincture of bark and water; and also used as gargle (in the proportion of 2 grains to a mixture of 7 ounces of water and 1 of honey). *Syphilitic ulceration of the larynx*, commonly known as *Syphilitic laryngitis*, is characterized by pain or tenderness in the region of the thyroid cartilage (see LARYNX), huskiness of the voice, a hacking cough from attempts to expectorate, with occasional expulsion of purulent matter mixed with blood. If the disease is not checked, enervation, night-sweats, and dangerous exhaustion, ensue, and life is often terminated by suffocation.

In noticing the secondary symptoms, *syphilitic iritis* must not be overlooked; its symptoms and treatment are described in the article IRITIS.

Our limited space precludes more than a very brief allusion to the more important *tertiary syphilitic affections*. The most important of these are those which attack the bones and their coverings. They may be included under the heads of acute and chronic periostitis (the latter being very common), nodes and exostosis, inflammation of bone, caries and necrosis; next to these are tertiary affections of the skin and mucous membrane, which consist mainly of intractable ulcerations attacking the face (especially the nose and lips), nails, ears, and mucous membranes of the various openings of the body; and diseases of the glands. In many of these cases, a modified form of mercurial fumigation is most useful; but if mercury, even in this form, is thought inexpedient, in con-

* A simple apparatus for mercurial fumigation, consisting of a kind of tin case containing a spirit lamp, may be procured from Messrs. Savigny and Co., St. James's Street, by those who object to rough bricks and coarse pans. A special fumigating cloak, in place of the blanket, is sold with the apparatus.

sequence of the general debility of the system, iodide of potassium, combined with any of the preparations of sarsaparilla, may be employed. Bark, iron, and the mineral acids are also of service in restoring the strength; and opium, by relieving the nocturnal pains which are so frequently present, will also prove most useful. The reader who wishes to pursue this subject further, may be referred to Aitken's *Science and Practice of Medicine*, in which he will find an account of the tertiary syphilitic affections of the nails, heart, brain, lungs, liver, and tongue.

The SYPHILIS OF CHILDREN is a subject which must not be omitted in an article on this disease. If the constitution of either the father or mother of an infant is saturated with the syphilitic poison, the child may be born with certain symptoms indicating that it is suffering from *congenital syphilis*. Moreover, the child of a mother having a primary sore, but no constitutional symptoms, may be inoculated with syphilis during the act of delivery; or the disease may be communicated in vaccination (if the matter be derived from an impure source); or by contact with syphilitic sores on the persons of wet-nurses or others. All these cases are included in the *infantile* variety of the disease. One of the most striking symptoms of true congenital syphilis is that which is popularly known as the *Snuffles*, in which a discharge collects in the nose, and sometimes blocks it up so completely that the infant is unable to suck for any length of time. The skin presents an eruption of spots, which are usually somewhat coppery, but sometimes of a rose-red tint; while on the soles of the feet and the palms of the hands, the cuticle scales off, and an appearance like that of psoriasis is presented; and flat mucous tubercles occur at the parts where the skin and mucous membrane merge into one another. White ulcers of a crescentic form often occur in the mouth; and with these symptoms there is nearly always observed 'the wizened and shrunken look, the anxious expression, and the dirty hue of the skin (a kind of dirty greenish yellow), which imparts to the infant a peculiarly repulsive aspect of old age.'—Holmes, 'On the Surgical Diseases of Childhood;' *op. cit.*, vol. iv. p. 830. Congenital syphilis frequently causes the death of the fœtus at about the fourth or fifth month; and if a woman is repeatedly delivered of dead children from the fourth to the seventh month, the practitioner may fairly conclude that a syphilitic taint is *probably* present. In other cases, the child is born alive with the 'snuffling' and eruption; but in the majority of cases, the infant when born is apparently healthy, and the disease does not show itself till about six weeks after birth.

When congenital syphilis is diagnosed with certainty, the medical attendant has a very important duty to perform, from which he must not shrink from any feelings of delicacy. He must discover which of the parents is affected, and must prohibit further cohabitation until the secondary symptoms have been completely removed by the treatment which has already been described. 'Neglect of this precaution,' says Mr. Holmes, in his excellent memoir on Congenital Syphilis (contained in the 4th vol. of his *System of Surgery*), 'may not only entail on the couple the misery of a family of deformed, puny, and ailing children, but to the woman at least is fraught with grave personal danger. Whatever may be the case amongst the poor, there is no doubt that, in the better classes, congenital syphilis is usually derived from the father, the mother being unaffected except through the fœtus.' There is scarcely a doubt that a woman carrying a syphilitic fœtus may become thus infected with secondary syphilis by the exchange of fœtal and maternal blood in the placenta; and this explains how it is that women who have never had the primary infecting sore occasionally show all the symptoms of secondary syphilis after living for some years with husbands similarly affected.

Allusion has already been made to the fact, that *infantile* (not *congenital*) syphilis may be communicated by vaccination. There is undoubted evidence that in the year 1861, in a thinly populated district of Piedmont, in which syphilis is virtually unknown, 46 children of various ages were simultaneously attacked with syphilis proceeding from chancres in the arm, and followed by buboes (enlarged glands) in the armpits; and that all these children had been vaccinated directly or indirectly from a single child, who was subsequently proved to have contracted syphilis from a wet-nurse; and further, that these children transmitted the same disease to a number of women, their wet-nurses, mothers, &c., and even to children who nursed and played with them; that the women so infected communicated the disease to their husbands; and finally, that the disease yielded in all cases to the ordinary treatment adopted in syphilis. This, as Mr. Holmes observes, is by far the most convincing instance of the propagation of syphilis by vaccination; but several others are recorded by Mr. Lee (*Lectures on Syphilitic Inoculation*, 1863) and other writers.

Cases in which the nipple of the wet-nurse has been infected by a syphilitic infant are by no means rare, and have in various instances given rise to litigation.

Congenital syphilis and infantile syphilis generally must be treated with mercury—either in the form of inunction, by keeping a flannel band, smeared twice a day with mercurial ointment, in constant contact with the thigh or arm for about six weeks; or internally, by the careful use of Gray Powder (*Hydrarg. c. cretâ*), in doses of a grain and a half or two grains, twice a day; combined with a little compound chalk-powder, if any irritation of the bowels occurs. The snuffles will be relieved by syringing the nostrils with lukewarm water, and then introducing a couple of drops of almond or olive oil.

In a foot-note to an early paragraph of this article, we gave abundant evidence of the appalling prevalence of this disease. In his valuable treatise on *Practical Hygiene*, Dr. Parkes discusses the question of the prevention of this disease amongst soldiers; as, however, his remarks for the most part are applicable to other classes, we shall briefly notice them. The means of prevention which he discusses are—1. *Continence*, which is promoted by (*a*) The cultivation of a religious feeling and of pure thought and conversation; (*b*) The removal from temptation and occasions to sin; (*c*) Constant and agreeable employment, bodily and mentally; and (*d*) Temperance. 2. *Early marriage*. At present, only six per cent. of our soldiers are allowed to marry. 3. *Precautions after the risk of contagion*. In some French towns, the use of lotions and washing is rigorously enforced, with the effect of lessening disease considerably. 4. *Cure of the disease in those affected by it.*

Health-inspections, in special reference to venereal diseases, are made weekly in our army by the surgeon or assistant-surgeon; and although similar inspections of all recognized prostitutes have long been made by legal authority in many parts of the continent, no attempt at legal interference with the disease in women was made in this country till 1864, when the 'Contagious Diseases Bill' was passed, by which, in the neighborhood of certain places (Portsmouth, Plymouth, Woolwich, Chatham, Sheerness, and Aldershot), prostitutes who are found diseased may be taken to a hospital, and there detained till cured. A committee appointed a few years before by government to report upon the best means of checking the disease in the army and navy, in February 1866, issued their recommendations; the most important of which are—(1) The periodic inspection of all known prostitutes in the garrison towns placed under the provisions of the act of 1864; (2) the appointment of a surgeon vested with the necessary powers; (3) punishment for infringement of the act; (4) the extension of its operation to all garrison and seaport towns used by troops or ships; (5) the prohibition of the residence of public women in beer-shops; (6) that the lock hospitals be placed under government control; and lastly, that the police supervision of the women in the streets of such towns be more stringent. The evidence taken seemed to prove that the working of the act of 1864 was useful. (A contrary report was issued in 1882.) For an account of the various plans which are adopted on the continent for the prevention of this disease—such as the registration of brothels and of prostitutes, and the enforcement of periodic examinations at short intervals—the reader is referred to the various works of Parent-Duchatelet, Acton, Sanger, and others on Prostitution; to Lancereaux's *Treatise on S.*; to Lee's *Lectures*; and to numerous articles in the medical and other reviews See CONTAGIOUS DISEASES ACTS.

Without entering into any prolonged details regarding the history of this disease, we may briefly mention that, towards the close of the 15th c., a great epidemic of syphilis pervaded Europe, and that it was supposed to have been imported from the New World; and that, in the 16th c., syphilis was recognized as the result of a specific virus. During last century, the history of this disease is divisible into three distinct periods, in each of which very different views have been prevalent. These may be described as—1. *The Period and Doctrine of Hunter*, who believed that the various forms of syphilis and gonorrhœa depend upon one and the same poison—a view taught by Carmichael in Dublin, Cazenave in Paris, and others. 2. *The Period and Doctrine of Ricord*, who proved that gonorrhœa was quite distinct from syphilis, and that inoculation with gonorrhœal matter will not cause a chancre; and that there are *two* classes of chancres, the *soft* and *hard*, originating from the same source. 3. *The Present Period*, commencing in 1856, in which it is held that, exclusive of gonorrhœa, there are *two* forms of the syphilitic poison. It has been judiciously advised by Mr. Longmore, the Professor of Military Surgery in the Army Medical School, that in accordance with our present knowledge of this disease, the term *syphilis* or *syphilitic* should be restricted to such cases as are believed to be of a specific infecting kind, while the term *local venereal sore*, or *venereal ulceration*, should be applied to those cases which require merely local treatment, and are not followed by constitutional symptoms.

SYPHILIZA'TION is the term used to designate an operation which has the double object of eradicating syphilis already existing in the system, and of securing permanent immunity from any future attacks, by means of repeated inoculations of syphilitic poison. As long ago as the year 1844, a French physician, Auzias

Turenne, undertook a number of experiments, with the view of testing whether John Hunter's view, that syphilis could not be communicated to the lower animals, was correct. After some failures, he succeeded in producing venereal sores (chancres) in monkeys, by inoculating them with the human virus; and he found that rabbits, cats, and horses might be similarly infected from the chancres of the monkey. He likewise found that the chancres produced by inoculation became less and less in each animal, until a period at length arrived at which the poison seemed to have lost all its power, and no further sores could be produced; and he was thus led to believe, that by prolonged inoculation, the system became protected. The subject was next taken up by Sperino of Turin, who inoculated patients suffering from syphilis by virus from a chancre, and repeated the inoculation once or twice a week, till the poison—as in the case of Turenne's animals—ceased to produce any effect; and when this point was reached, all the other sores had healed.

In 1851, Professor Boeck of Christiania, when traveling through Italy, had his attention drawn to the doctrine of syphilization; and from that time to the present, he has devoted himself unremittingly to it, and is now the great authority on the subject. In 1858, Boeck, in consequence of the results he had attained from the practice of S. in cases where no mercurial treatment had been prescribed, alleged that S. might in such cases be regarded as a complete and certain cure. In cases where mercurialization has been practised, the use of iodine has to be persisted in during S. During the summer of 1865, Dr. Boeck visited London, and took active steps to make his views on this subject accurately known in this country, and the surgeons of the Lock Hospital submitted a series of cases to his mode of treatment; and Mr. James Lane, one of the surgeons to that institution, asserted in 1866 that 'hitherto, as far as he had seen, it had effected everything which had been promised for it. The progress of the cases in the Lock Hospital had in almost every detail corresponded to the predictions of Professor Boeck respecting them. In several of those who had been longest under treatment, immunity from inoculation with primary syphilitic matter had been arrived at.' The progress of S. as a remedy for syphilis and as a proof against syphilitic infection, has not been well marked in this country. Most surgeons are agreed as to the correctness of Professor Boeck's views, but the practice itself is offensive, and the length of time necessary for its being effectively carried out forms an objection to its practice. In Sperino's experiments, the treatment extended from 9 to 20 months or more. The practice has been much in vogue in Christiania under Boeck and his colleague M. Bidenkap; but it is unlikely to command attention other than of scientific kind, and as tending to acquaint us with the history of syphilis and with the nature of syphilitic infection.

SY'RA (Gr. *Syros*), the most important though not the largest member of that group of islands in the Ægean Sea known as the Cyclades (see GREECE), lies 13 miles south of Andros. It is about 10 miles long by 5 broad, bare, hilly, and not very fertile. The products are wine, tobacco, grain, citrons, figs, honey, and vegetables; but the greater portion even of the common necessaries of life have to be imported from Greece and foreign countries. Its prosperity is of quite modern growth. During the War of Independence, S. remained neutral, and, in consequence, numerous fugitives flocked thither from other parts of Greece, especially from Chios and Psara, who, besides adding largely to the population, brought with them a spirit of political activity and commercial enterprise, the beneficial effects of which are now strikingly visible. Pop. 26,946. The capital, *Syra*, or *Hermopolis*, is situated on a bay on the east side of the island. It rises terrace-wise from the shore, is well built, and is the seat of government for the Cyclades, and the residence of foreign consuls. It has numerous educational institutions, 4 printing-presses, and 3 weekly newspapers. S. has become the great commercial entrepôt of the Ægean. Nearly one half of all the imports of Greece reach it through this port. It builds more ships than any other town in the Levant, and owns one-third of all the Greek merchantmen. It has likewise regular steam-communication with all the principal trading-towns in the Levant. Pop. of the town of S. (1879) 4398.

Ancient notices of S. are scanty. Homer praises it in the *Odyssey* as 'rich in pastures, in herds, in wine, in wheat;' but it has no history.

SY'RACUSE, anciently the most famous and powerful city of Sicily, situated on the south-eastern coast of the island, 80 miles south-south-west of Messina, was founded by a body of Corinthian settlers under Archias, one of the Bacchiadæ, 734 B.C. The original colonists seem at first to have occupied nothing more than the little isle of Ortygia, about one mile long, and half a mile broad, which lies near the shore. It rapidly rose to prosperity, and was enabled to establish sub-colonies of its own: Acræ (664 B.C.), Casmenæ (644 B.C.), and Camarina (599 B.C.). Nothing definite is known of the early political state of S.; but before 486 the political power had passed into the hands of a few leading families, or perhaps *clans*, who constituted an oligarchy, while the great body of the citizens formed a malcontent democracy. In that year a revolution took place. The oligarchic families—*Geomori* or *Gamori*, 'landowners;' probably the descendants of the original colonists, like the patrician *gentes* of Rome—were expelled, and the sovereign power was transferred to the citizens at large. Before a year passed, however, Gelon (q. v.), 'despot' of Gela, had restored the exiles, and at the same time made himself master of Syracuse. He was a great ruler, and under him the city increased in size and wealth. It is believed to have been in Gelon's time that the adjoining mainland was first built upon.

The locality of the new settlers was the slopes and heights of Achradina, or the 'outer city,' a triangular table-land north of the island of Ortygia, and subsequently connected with it by a mole. It ultimately became the most extensive and populous quarter of S.—contained the Agora, a temple of Zeus Olympios, the Prytaneum, with a splendid statue of Sappho, the fine monuments to Timoleon and the elder Dionysius (q. v.), &c. It may be convenient to mention here the other two quarters of the city, especially as the date of their settlement is not known. These were Tyche—so called, according to Cicero, from an ancient temple of 'Fortune' erected there—occupying a plateau to the west of Achradina; and Neapolis (New City), stretching along the southern slopes of the plateau, and overlooking the marshes of the Anapus and the 'Great Harbor,' a spacious and well-sheltered bay, about five miles in circumference. Neapolis became one of the finest parts of Syracuse. Here were situated the theater, amphitheater, and numerous temples, of which hardly a relic remains, except of the first mentioned. Ortygia contained the castle or citadel which immediately fronted the mainland, and overlooked the docks or *navalia* in the 'Lesser Harbor.'

Reverting to the history of S., which we must touch upon only in the most cursory manner, a noticeable characteristic of the reign of Hiero (q. v.), the successor of Gelon, is his cultivation of the fine arts, and his liberal patronage of men of genius, as Æschylus, Pindar, &c. In 466 B.C., the democracy again got the upper hand—Thrasybulus, a 'tyrant' of the baser sort, being expelled; and for sixty years a free and popular government was enjoyed, under which S. flourished more than it had ever done. During this period occurred its great struggle with Athens (415—414 B.C.), in which it came off victorious, and its renown at once spread over the whole Greek world. But a new power appeared on the stage—the Carthaginian, whose conquests in Sicily, towards the close of the 5th c., threatened the supremacy of Syracuse. Meanwhile, Dionysius (q. v.) restored the 'tyranny' of Gelon, and during a reign of 38 years greatly increased the strength and importance of the city. It was he who constructed the docks in the Greater and Lesser Harbors, and surrounded the city with fortifications. His fierce and victorious war with Carthage (397 B.C.) raised the renown of S. still higher. The reigns of the younger Dionysius (q. v.) and of Dion were unsettled; but after the restoration of public liberty by Timoleon (344 B.C.), a brief season of tranquillity ensued, during which the prosperity of the city rapidly revived. Under Agathocles, however, the despotic form of government was again established (317 B.C.), and continued, with scarcely an interruption, down to the conquest of the city by the Romans (212 B.C.) during the Hannibalic war—the ruler of S., Hieronymus, a rash and vain young man, having abandoned the prudent policy of his grandfather, Hiero (q. v.), broken the alliance with Rome, and joined the Carthaginians.

Under the Romans, S. slowly but surely declined, though it always continued to be the capital and first city of Sicily. Captured, pillaged, and burned by the Saracens (878 A.D.), it sunk into complete decay, and is at present confined to its original limits, Ortygia, which, however, is no longer an island, but a peninsula. Pop. (1881) 23,507. The streets of the modern town are, with few exceptions, narrow and dirty. S. has a cathedral, a museum of classical antiquities discovered in S. and the neighborhood, a public library, with some curious MSS., numerous churches, monasteries, and nunneries, and carries on a trade chiefly with Malta in wine, oil, salt, and salt-fish. It has several remains of ancient and medieval edifices, which are much visited by travelers.

SYRACUSE, a city of Central New York, U.S., at the head of Onondaga Lake on the Erie Canal, and at the junction of the New York Central and Oswego railways, 148 miles west-by-north of Albany. From its central position, it is called the City of Conventions. It contains a handsome court-house, state arsenal, state asylum for idiots, 41 churches, 3 daily and 11 weekly newspapers, 13 banks, schools, and libraries. Here are the largest salt-works in America (producing, in 1874, 6,029,300 bushels of salt), 5 iron-furnaces, 14 machine-shops, manufactories of silver, tinware, sheet-iron, coach and wagon factories, and breweries. Pop. (1880) 51,792.

SY'RIA (Arab. *E'sham*, Turk. *Soristan*), a division of Asiatic Turkey, bounded on the N. by portions of Asia Minor, on the W. by the Levant, and on the S. by Arabia Petræa; on the E. and S.-E., its boundary is rendered indefinite, in great part, by the sands of the desert, but at length becomes fixed by the course of the Euphrates. It is divided into several governments, which frequently change their limits. They are usually named after the principal towns—Aleppo, Damascus, and Beyrout. The area is about 146,000 square miles; pop. about 2,250,000. The whole region is traversed by a double mountain-chain—of which Lebanon (q. v.) forms the highest part—touching in its northern extremities the Alma Dagh (anc. *Mons Amanus*), and in its southern forming the Sinaitic range. The central part of this mountain-system, which in many places exhibits the characteristics of a plateau, presents on the west a steep front towards the Mediterranean, but on the east rolls gradually away into the level uplands of the Syrian wilderness. The most noticeable features of the long *furrow* between the double ridge, beginning at its southern end, the Gulf of Akaba, are, the waterless wady of Arabah, the narrow, deep-sunken region known as *El Ghur*, through which the river Jordan flows, and which embraces the Dead Sea and the Sea of Galilee, and the vale of Cœle-Syria (q. v.), and its great continuation northwards, watered by the Nahr-el-Asy (anc. *Orontes*). The western ridge is broken through in three places: in the north by the lower Orontes; in the middle near Tripolis—where the chain of Lebanon properly terminates—and further south, near Tyre, by the Leontes. South of Tyre, it recommences in the hill-country of Western Palestine (q. v.), which finally passes into the desert plateau of El Tyh, in the Sinaitic peninsula.

The eastern ridge is less sharply defined; its most conspicuous elevations being Anti-Libanos, the mountains of Moab (east of the Dead Sea), and Mount Seir, overlooking the wady Arabah. The principal rivers are the Orontes (q. v.), the Leontes, the Jordan (q. v.), the Barada or Abana, the river of Damascus. The only lakes worth mentioning are the Dead Sea (q. v.) and the Sea of Galilee.

Although S. belongs to the countries comprised within the Asiatic rain-zone, yet in general the climate is excessively dry and hot, differing little from that of Arabia. Drought and scantiness of vegetation characterize almost equally the uplands and the valleys. Only where the mountains are lofty, the streams abundant, and the atmosphere somewhat maritime, as in the terraced slopes of Lebanon, do we find some approach to tropical luxuriance in flower, and fruit, and tree. Forests of evergreens, beautiful grassy pastures, and meadow-tracts are found there; and wheat, maize, rice, &c., are largely produced. The cultivation of the vine, the cotton-tree, the mulberry, and also the finer sorts of fruits, as the olive and fig, is considerable, while indigo and sugar-cane are raised in the valleys of the Jordan and the region round about the Dead Sea. The fauna of S., like its climate and vegetation, is similar to that of Arabia. The camel is of almost as much importance as further south; and the Syrian deserts, particularly towards the north, are the home of gazelles, hyænas, jackals, bears, buffaloes, and other wild animals.

The greater part of the Syrian mountains is limestone; mountain limestone in Lebanon, chalk in Anti-Lebanon, and Jura limestone in Palestine. In the last of these, volcanic formations occur, especially in the region of the Jordan and the Dead Sea, where hot springs, beds of bitumen and sulphur, the shapes of the hills, and the frequent earthquakes, afford unmistakable evidence of volcanic activity. Salt is the only mineral of much consequence, and is exported in considerable quantities; coal, however, is worked near Beirût. Sheep, goats with hanging ears and silky hair, cattle, mules, and asses, form, as in ancient times, a great part of the wealth of the inhabitants.

Silk is the chief article of manufacture—at Aleppo, Beirût, Damascus, &c.—but cotton and woollen fabrics, gold and silver thread-stuffs, glass, earthenware, leather, soap, &c., are also manufactured in different parts of the country. The want of roads is a great hindrance to industrial activity. The first carriage-road was opened in 1863, between Beirût and Damascus. The other roads, with the exception of one or two short carriage-ways in Mount Lebanon, are mere mule and camel tracks. In 1871, S. exported grains, seeds, cotton, galls, wool, &c., to the value of £717,404; and imported cottons, woollens, copper, tin, iron, coals, indigo, pepper, coffee, &c., to the value of £1,338,750.

The *religious* sects of S. are numerous. Most of the people are Mohammedans; but Christians of the Greek Church number 180,000; Maronites (q. v.) and Roman Catholics, 310,000; Jews, 40,000; Druses (q. v.), 90,000; lesser sects about 30,000. The inhabitants are in some sense a mixed people, for the country has experienced many political vicissitudes; but by far the greatest number, whether Christians or Mohammedans, are of Shemitic origin, either Phœnician, Aramæan, or Arabic. Their Turkish rulers, however, and such Turkomans and Kurds as we find settled in the north of S., belong to the Turanian race. Arabic is everywhere spoken, and may be considered the national language, since the old Syriac or Aramaic tongue is wholly dead, except among the Nestorians of Kurdistan.

The *history* of S. stretches far back into remote antiquity. In the time of Abraham (2000 B.C.), Damascus was a city; in the oldest literature of Greece, Sidon figures as the capital of a rich, populous, and civilized state; and in the Hebrew Scriptures, Canaan or Palestine is crowded with towns at the period of its conquest by Joshua; but, like most other so-called nations in early times, S. did not form a single state; it was rather a congeries of independent states whose inhabitants belonged to the same race. Every important city had its king, whose normal occupation was fighting with his neighbors.

Under David and Solomon, something like political unity was achieved; yet it does not appear that these great rulers dispossessed of their territories the princes whom they subdued, but only made them tributary, and after their death things reverted to their previous condition. Rezin, a slave, then made himself master of Damascus, and extended the Damascene monarchy over all Northern and Central S.; but the conquests of Tiglath-Pileser resulted in its becoming a province of the Assyrian Empire. Subsequently, the whole land, including Palestine, became part of the successive empires of Babylonia, Media, Persia, and Macedonia. Then followed the dynasty of the Seleucidæ (q. v.). After their fall, S. passed into the hands of the Romans, who retained it, though not continuously—for on several occasions the Persian Sassanidæ (q. v.) managed to wrest it from them—until the Arab conquest (7 c. A.D.). During the Crusades (q. v.) of the middle ages, several Christian principalities were established here, but endured only for a short period. S. now became a possession of the sultans of Egypt, in whose time it was frightfully devastated by the Mongols. In the 16th c., it was conquered by the Turks, and has ever since formed part of the Turkish Empire.

SY'RIAC VERSIONS. Apart from the Peshito (q. v.), there were other Syriac versions of the Old Testament current among the Syrian Christians, although they did not acquire canonicity among them. These were chiefly translated from the LXX., and the best known among them is one drawn up from the text of the Hexapla (q. v.; compare also ORIGEN), which it follows most slavishly, without any regard for Syriac idiom or grammar. It contains the critical remarks of Origen, and is moreover furnished with numerous variants, fragments from other Greek versions, and exegetical scholia. Bishop Paulus of Tela is supposed to have composed it at the instigation of Bishop Athanasius, 617 A.D. There are now only a few (imperfect) MSS. extant of it—one in Paris, one in the Ambrosian Library (a third, once in the possession of T. Masius, has disappeared), and further portions are found in the Nitrian collection in the British Museum. The greater part of the Biblical books has been edited from it, but in separate publications. A complete edition is still a desideratum. An attempt is now being made towards a more complete edition of the Hexapla itself, by a reconstruction of lost portions of the Greek, through the medium of the parallel Syriac passages preserved in this translation. Two other MSS. in the Paris Library contain fragments of another Græco-Syriac version, by Jacob, Bishop of Edessa, who, in 703 and 704 A.D., composed it from the Peshito and the above translation, which is probably to be understood in the sense of his having made a new recension of Paulus of Tela's work, corrected after the Peshito.

SYRIAN RITE, CHURCH OF, that portion of the oriental church which had its seat in Syria, and which was anciently comprehended in the patriarchate of Antioch, and (after that of Jerusalem obtained a distinct jurisdiction) in the patriarchate of Jerusalem. The Syrian Church of the early centuries was exceedingly flourishing. Before the end of the 4th c., it numbered 119 distinct sees, with a Christian population of several millions. The first blow to the prosperity of the Syrian Church was the fatal division which arose from the controversies on the incarnation. See MONOPHYSITES, NESTORIANS, EUTYCHES, JACOBITES. The Eutychian heresy, in one or other of its forms, obtained wide extension in Syria; and the usual results of division ensued in the corruption and decay of true religion. The Moslem conquest accelerated the ruin thus begun; and from the 7th c. downwards, this once flourishing church declined into a weak and spiritless community, whose chief seat was in the mountains, and whose best security from oppression lay in the belief on the part of the conquerors of their utterly fallen and contemptible condition. Under the head MARONITES has been detailed the most remarkable incident in the later history of the Syrian Church. This branch of the eastern Christianity, although for the most part divided from the orthodox Greek Church by the profession of monophytism, took part with the Greeks in their separation from the west, under Michael Cerularius; and the reunion of the Maronites to Rome had the remarkable result of establishing side by side, within the narrow limits occupied by the Christians under the Moslem rule in Syria, two distinct communities, speaking the

same language, using the same liturgy, and following the same rites; and yet subject to two different patriarchs, and mutually regarding each other as heretics and apostates from the ancient creed of their country.

The chief peculiarity of the Syrian rite, as contra-distinguished from the Greek, consists in its liturgy, and the language of that liturgy, which is Syriac, and with which the people, and in many cases the priests, are entirely unacquainted. The liturgy is known as the Liturgy of St. James. The Syrians agree with the Greeks in the use of leavened bread, in administering communion under both heads, in permitting the marriage of priests (provided they marry before ordination), and in administering the unction of confirmation at the same time with baptism even to infants.

The Christian community of Syria may at present be divided into four classes: the Maronites, the Greeks (who are also called Melchites), the Monophysites, who are called Jacobites, and the primitive Syrian Christians (not Maronites), who are in communion with Rome. This last-named community forms the small remnant of the ancient Syrian Church, which remained orthodox during the controversy on the Incarnation, at the time of the general lapse into Monophytism. To these are to be added the Christians of the Latin rite and a few Protestants. The Maronites number about 160,000; the Greeks are said to be about 180,000; the Jacobites of Syria and of Armenia Proper are said to reckon together about 40,000 families, of whom, however, probably scarcely 10,000 can be set down to the account of the Syrian Church. The non-Maronite Syrians who follow their national rite, but are in communion with Rome, are supposed to amount to about 5000. The resident Latins are chiefly members of the religious orders who from immemorial time possess convents in the Holy Land, and European Catholics, who have settled permanently, or for a time, at Jerusalem, Beirût, and Damascus. None of these can in any way be regarded as belonging to the Syrian Church.

It may be well to add, that the belief, and in most particulars the disciplinary practice of these several classes coincide substantially with those respectively of the same communities in the other churches of the East. All (with the exception of the Maronites and the few United Syrians) reject the supremacy of the Roman see. The Syrians of the Greek communion reject the double procession of the Holy Ghost; and the Jacobites firmly maintain their old tenet of Eutychianism. Among them all are to be found monks and religious females. All enforce celibacy on their bishops, and refuse to priests the privilege of contracting a second marriage, or of marrying after ordination. The practice of fasting prevails among all alike. They receive and practise the invocation of saints and prayers for the dead, and the use of painted, although not of graven images. Many particulars regarding them are to be gleaned from the memoirs of recent missionaries of the several denominations, among which the letters published from time to time by the French Society for the Propagation of the Faith, are particularly full. For the modern Nestorians, and the Syrian Christians of Travancore, see NESTORIANS.

SY'RINGE (Gr. *syrinx*, a pipe), a hydraulic instrument, consisting of a cylinder of metal or glass, having a conical nozzle at one end, and the other fitted with an air-tight piston. The nozzle being inserted in a liquid, the retraction of the piston draws the liquid into the cylinder, on the principle of the pump (q. v.), and by its forward pressure the liquid is expelled from the nozzle in the form of a jet.

SYRRHA'PTÉS, a genus of birds of the Grouse family (*Tetraonidæ*), of which only one species is known (*S. Pallasii*), a native of the deserts of Tartary, abundant in the neighborhood of Lake Baikal. From its peculiar characters, which led Pallas to call it *Tetrao paradoxus*, it has received the somewhat pedantic name of *Heteroclite Grouse*. (A word is called *heteroclite* by grammarians which departs from the ordinary forms of declension.) The legs and toes are short, and densely feathered; and the toes are joined together for the greater part of their length. The bird walks with difficulty, but flies very well, although in general only for short distances. The wings and tail are very long, terminating in remarkably long, slender, pointed plumes.

SY'RTIS MA'JOR AND SYRTIS MI'NOR, the ancient name of two gulfs of the Mediterranean Sea, on the north coast of Africa. The former (now called the *Gulf of Sidra*) lies between Cape Mesurata, in Tripoli, and the table-lands of Barca, and forms the most southern part of the Mediterranean. The latter (now called the *Gulf of Cabes*) lies to the north-west, between Tunis and Tripoli. The shores of both are inhospitable, and abound in quicksands, which, carried by the wind, are said by the ancients to have frequently overwhelmed ships, and the reports of modern travelers to some extent confirm these old traditions. Their waters are (or were) dangerous to sailors, on account of the shallows, sandbanks, and sunken rocks that abound in them.—The name Syrtis is derived from an Arabic word, *Sert*, meaning a desert.

SY'RUP. *Syrup*, *sherbet*, and *shrub* are all derived from the Arabic *srb;* the first through the Latin, the second through the Persian, and the third through the Hindu. Syrup, in its simplest meaning, is a saturated solution of sugar boiled to prevent fermentation; but it also means the juice of fruits saturated with sugar and many flavored liquids, treated in the same way. Generally speaking, the finest refined sugar is used; and every effort is made to get the syrup very clear and free from all feculent matter. Syrups of fruits are much used on the continent to mingle with water for drink, and are very wholesome. They are also used in Britain, but not much, except in medicine—there being many medicinal syrups.

SY'STYLE, an arrangement of classic columns in which the intercolumniation is equal to twice the diameter of the column.

SYZRA'N, a town of Central Russia, in the government of Simbirsk, on the right bank of the Volga, about 150 miles below the town of Simbirsk. It owes its foundation to its advantageous commercial position on the Volga, and in the middle of a district teeming with agricultural produce. From the wharfs of S., 150 vessels, laden with corn, are annually despatched to Rybinsk and St. Petersburg. Pop. (1880) 19,450.

SZA'RVAS, a town of Hungary, in the county of Bekes, in a plain on the Kőrös, 22 miles north east from Csongrad. It has a considerable trade in corn and cattle. Pop. (1880) 22,504.

SZATHMA'R-NEME'THY, a town of Hungary, on the Samos, 60 miles north-east of Debreczin. Pop. (1880) 19,708.

SZE-CHUE'N (Four Streams), a vast province of Western China, and the largest of the eighteen. It has an area four times greater than that of England, but the population is scanty. The Kincha-kiang, or 'Golden Sanded River,' which rises in the southern slopes of the great Tibetan range, flows through S., and after receiving several tributaries, it becomes, before leaving the province, the famous Yang-tze-kiang. In its course, it passes at right angles, and by narrow gorges, through a succession of ranges of hills, which have a direction from north to south. The people of S. cannot always force a subsistence from their stubborn soil. Famines are not uncommon, when whole families are starved to death, and thousands subsist on a mixture of rice, roots, and common earth. Coal is abundant, but of inferior quality; seams of from three to five feet in thickness are laid bare in the gorges cut by the Yang-tze, and gold is found in small quantities.

SZEGEDI'N, till lately the second largest town in Hungary, but almost completely destroyed by a terrible flood in March 1879. In this hardly paralleled catastrophe, of the 7000 houses of the city, only 350 were left standing. The ruin to property was immense; the loss of life was given at 2000. S. stands (or stood) on the low ground where the Theiss is joined by the Maros, 118 miles S.E. of Buda-Pesth. In its normal condition, it manufactures great quantities of soda, tobacco, coarse cloth, &c., has the largest wharfs on the Theiss, and carries on an extensive river-trade in wood and corn with Transylvania. Its markets rank next to those of Pesth and Debreczin. Pop. (1880) 73,675.

SZEGSZA'RD, a town of Hungary, near the right bank of the Danube, 80 miles south-south-west of Pesth. Here excellent red wine is made. Pop. (1880) 11,948.

SZE'NTA. See ZENTA.

SZENTE'S, a market-town of Hungary, 30 miles north of Szegedin, near the left bank of the Theiss. The *commune* contains (1880) 28,712 inhabitants, who are chiefly engaged in the wine-culture.

SZOLNO'K, a town of Hungary on the Theiss, 66 miles east-south-east of Pesth. It contains important salt-magazines, and is the center of the traffic by steamers on the Theiss, and an important railway station. Pop. (1880) 18,247.

T.

THE twentieth letter of the English alphabet, is the sharp or mute of the lingual series, *t*, *d*, *th* (*dh*). It is produced by pressing the forepart of the tongue against the front of the palate. The name in Shemitic (*Tau*) signifies a mark (in the form of a cross). The Shemitic tongues had another *t*-sound, which became the Greek θ (*th*). This aspirated *t* is wanting in Latin and its derivatives; it is also foreign to High-German, although the Gothic and other Low-German tongues (English) possess it. The Gothic *th* has become in High-German *d*. In the *spelling* of High-German, *th* occurs not unfrequently; but it is never pronounced, and the introduction of it being considered by students of the language an aberration, there is a tendency to drop the *h*.

There is evidence that in Latin, at an early period, *t* before *i* was sibilated so as to sound like *ts* or *z*. See letter C. Before *s*, *t* was frequently dropped; as *fons* for *fonts*, *sors* for *sorts*. Final *t* was in Latin pronounced but faintly, and inscriptions show that in popular speech it was often dropped; e. g., *fece* for *fecit*, *vixse* for *vixit*. Thus the modern Romanic languages have inherited the loss of the pronominal ending *t* from their common mother. In French, *t* between two vowels has been elided; as *père*, *mère*, from *pater*, *mater*. In the corresponding words of the allied languages, *t* is often interchanged with other letters. T in Sanscrit, Greek, and Latin becomes *th* in Gothic and English, and *d* in High-German; thus Lat. *tres* (Sans. *trayas*), Goth. *thrais*, Eng. *three*, Ger. *drei;* Lat. *tectum* (Gr. *tegos*), Goth. *thak*, Eng. *thatch* or *thack*, Ger. *dach;* Lat. *frater*, Goth. *brothar*, Eng. *brother*, Ger. *bruder*. In German, the *t* of the English is often represented by *z*, as Eng. *two* = Ger. *zwei;* Eng. *toll* = Ger. *zoll;* while German *t* or *th* becomes Eng. *d*, as Ger. *tag*, *thau* = Eng. *day*, *dew*. A more remarkable interchange is seen it Lat. *lacrima* = Eng. *tear*. See PHILOLOGY.

TABA'NIDÆ, a numerous family of Dipterous insects, of the section *Proboscideæ*, which live by sucking the blood of horses, oxen, and other animals, and are popularly known by the name of GAD-FLY, which, however, is often given also to some of the *Œstridæ* (see BOT). The insects called CLEG (q. v.) are of this family. The proboscis is exserted, and is generally terminated by two lips; the palpi are also exserted; the antennæ are three-jointed, the third joint consisting of a number of rings. The T. fly with

Gad-fly and larva (*Tabanus bovinus*).

a buzzing noise. They are very annoying to cattle in the end of spring and early part of summer; and where they abound, the skins of cattle are often streaked with blood from their bites. The LARGE GAD-FLY (*T. bovinus*) is more common in some parts of the continent of Europe than anywhere in Britain, and is rarer in Scotland than in England. But the British T. are numerous. The species are widely distributed. Some of them inhabit the deserts of Arabia and Africa, and attack camels in prodigious numbers.

TA'BARD (Fr. *tabarre*, from *tabardum*, Low Lat.), a military garment in general use in the latter half of the 15th and beginning of the 16th c., which succeeded the *Jupon* and *Cyclas*. It fitted closely to the body, was open at the sides, had wide sleeves or flaps reaching to the elbow, and displayed the armorial ensigns of the wearer on the back and front, as well as on the sleeves. About the middle of the 16th c., the tabard ceased to be used except by the officers at arms, who have down to the present time continued to wear tabards embroidered with the arms of the sovereign.

TABASHEE'R, a substance sometimes found in the cavities or tubular parts of the stems of bamboos and other large grasses. It consists chiefly of silica, with a little lime and vegetable matter, or sometimes of silica and potash, in the proportions of about 70 parts of silica and 30 of potash. It appears to be formed by extravasation of the juices of the plant, in consequence of some diseased condition of the nodes or joints. It is in high repute among the Hindus as a tonic, and is prepared by imperfect calcination and trituration. The powder is often chewed with betel, in order to renovate the constitution. There are several varieties of tabasheer, one of which, of very rare occurrence, is extremely beautiful, of a delicate azure color by reflected light, and of a faint yellowish hue by transmitted light, easily crushed between the fingers, and of 'an aërial and unsubstantial texture, which we look for in vain in any other solid.' Other varieties are yellowish, white, and much like some varieties of opal.

Tabasheer is very porous, and absorbs water and oil very rapidly; effervescence taking place when it is plunged in water. By absorption of oil, the opaque varieties become transparent. When the greater part of the oil is expelled by heat, the structure of the tabasheer becomes apparent; it is beautifully veined, the veins being sometimes parallel, and sometimes curved. The optical properties of tabasheer are remarkable. Of all known substances, it has the lowest refractive power.

TABBY, or TABBYING, another name for watering fabrics. See MOIRE. It is usually applied to stuffs or worsted cloths instead of silks.

TA'BERNACLE (Heb. *Ohel Moed* = tent of meeting, *scil.*, between God and man; LXX. *Skene*, Vulg. *Tabernaculum Fœderis*), or, more fully, 'Tabernacle of the Congregation,' was the tent first erected by Moses in the desert as a visible symbol of the Divine Presence in the midst of the people. It was the place where he went to receive his inspirations as their representative, when 'they came to seek Jehovah.' A cloudy pillar descended and stood at the door of the Tabernacle while 'the Lord spake to Moses.' The detailed description of the Tabernale contained in Ex. xxv. seqq., xxxvi. seqq., renders more than a brief outline superfluous in this place. Suffice it to mention that it was divided into the 'Sanctuary' proper—which formed the front part, and the dimensions of which were 20 cubits in length, 10 in width, and 10 in height—and the 'Holy of Holies,' which was 10 cubits square, and 10 high. A kind of court-yard, formed by curtains suspended between columns, ran round the Tabernacle, 100 cubits long, and 50 wide. The entrance was towards the east—the rising of the sun—and closed by another costly curtain, into which, like unto the first covering, figures of 'cherubim' were woven.

The surrounding court was much larger on this eastern than on the western side, for here it was that the people assembled for the purpose of worship. Here also stood the altar, made of acacia-wood, upon which a perpetual fire was kept burning, and the brazen laver. The *Sanctuary* contained the gilded table with the showbread to the right, the golden candlestick with the seven branches to the left, and between both the 'golden altar,' or the 'altar of incense,' upon which the high-priest burned incense in the morning and evening. In the Holy of Holies, the holy ark, or Ark of the Covenant, alone was kept: a box of acacia-wood, plaited with pure gold both in and outside, containing the two tables of the Ten Commandments. On the top of it were the two cherubim, their faces turned towards each other; and between them there was the symbolical presence of Jehovah (the Shechinah), to which Moses appealed for guidance.

Only once a year, on the Day of Atonement, the high-priest was allowed to enter the Holy of Holies, while the Sanctuary was the ordinary place of the priests, and the court that of the Levites. The tribe of Levi was also that to which the place nearest to the Tabernacle, around which the twelve tribes were grouped, was assigned, as it also was the duty of its members to convey the building from place to place during the migrations.

The Tabernacle, after the people had settled in Canaan, was erected at Shiloh, where it was still found at the time of Saul, although the Ark of the Covenant itself had been carried away by the Philistines, in the time of Eli, and when restored, placed at Kirjath-jearim. Nor was the Tabernacle of Shiloh the only sanctuary, as it was intended to be. We find other local sanc-

tuaries with priests—at Bethel, Nob, Sichem, Mizpah, &c.—at which even Samuel worshiped, as in legally instituted places. When David is reported to have removed the Ark from Kirjath-jearim to Jerusalem, nothing is said about the Tabernacle of Shiloh; on the contrary, David erected a new one on purpose for the Ark. It seems probable that it was removed at some time or other from Shiloh to Nob, and thence to Gibeon, from whence Solomon seems to have fetched it away, with all its vessels, thus putting an end to the double worship that under David had divided the faithful between Gibeon, where Zadock officiated, and Jerusalem, with Asaph's worship. Nothing is further known of the Tabernacle, which besides being a symbol of God's presence, had also served the purpose of a visible political and religious link between the tribes. As a safeguard against idolatry and unlimited sacrificial worship, however, it did not prove effective enough.

TABERNACLE (Lat. *tabernaculum, armarium*), in the Roman Catholic Church, is the name given to the receptacle in which the consecrated elements of the Eucharist are retained. The name is derived by analogy from the tabernacle of the Old Law, and in form the Roman Catholic tabernacle bears a general resemblance to the Jewish original. By the present discipline, the tabernacle is commonly a small structure of marble, metal, or wood, placed at the posterior part of the altar, and of costly material and workmanship. Even when the exterior structure is of marble or metal, there is commonly an inner receptacle of wood (properly cedar), lined with silk. The tabernacle is appropriated exclusively to the reservation of the Eucharist, and it is prohibited to keep within it any other object, however sacred, as the chrism, relics of saints, the altar-vessels, &c. A lamp is constantly kept burning before the tabernacle, which is ordered to be kept at all times carefully locked, the key being retained by the clergy, to whom it is forbidden to intrust it to any lay person, even the sacristan or other official of the church.

TABERNACLES, FEAST OF (Heb. *Succoth*, LXX. *Heorte skenon*, Vulg. *Feriæ Tabernaculorum*), a Hebrew feast of seven days' duration, beginning on the fifteenth day of the seventh month (Tishri), and instituted principally in memory of the nomad life of the people in the desert, and the booths or tents used on their march. Besides this signification, it also had an agricultural one, like the other two pilgrimage festivals, the Passah and the Feast of Weeks. It was emphatically the Feast of 'Ingathering'—i. e., the close of the labors of the field—the harvest of all the fruits, of the corn, the wine, and the oil. During this feast, the great bulk of the people were enjoined to dwell in booths, which we learn from Nehemiah viii. 15, were made of olive, pine, myrtle, palm, and other branches, and were erected on the roofs of houses, and in the courts and streets. The scriptural injunction, to take trees and 'boughs of goodly branches of palm-trees,' &c., was by tradition explained to mean a bunch made of palm, myrtle, and willow branches, and the esog-fruit, a species of citron, which the faithful carried in procession during these seven days in the Temple; while those who did not visit the Temple only said a benediction over it on the first day. The Sadducees and Karaites, however, demurred to this explanation, taking the passage merely to refer to the construction of the booths. Special sacrifices, and a greater number of burnt-offerings than on any other festival, were offered up on this; and on it also the law was to be read to the people every seventh year. It was emphatically called *the* festival, and was the most joyous of them all.

There was especially, during the time of the Temple, the 'joy of the libation,' consisting of the priest's fetching, during the morning sacrifice of each day, water from the well of Siloah, and pouring it out, with the accompaniment of music and hymns. There was further a grand illumination in the evening in the court of women, which is said to have lighted up the whole city of Jerusalem; and during and after which, dancing and singing took place. On each day the trumpets were sounded 21 times. At the end of the seven days' joy, an eighth day of solemn rest was celebrated, which was perfectly distinct from the other days both in its sacrifices and in its general service. The bunch was laid aside, the booths were relinquished, and a sin-offering—in expiation of transgressions that might have taken place during the hilarity of the previous feast-days—was slaughtered.

Three distinct times we find the inauguration of the Temple celebrated on this important festival, by Solomon, Ezra, and Judas Maccabæus, although with regard to the festival itself, it would seem from Nehemiah viii. 17, that it never had been properly celebrated before the Exile. The observances of the booths and the harvest-bunches are still in force with the strict adherents of traditional Judaism, although the agricultural signification of the festival to them can only be a historical or poetical reminiscence. It has been well observed of old, that no festival could have been more apt to inculcate the fundamental principle of Judaism—viz., the equality of all men, than this, which enjoined that every one should live for a time in primitive dwellings, without distinction of rank or station, or fortune, and should rejoice in the fruits of the last harvest on the hallowed spot, together with the whole people of the land, 'before the Lord.'

TABE'RNÆMONTA'NA. See COW-TREE and FORBIDDEN FRUIT.

TA'BES DORSA'LIS, an affection of the nervous system, now known in medicine as *locomotor ataxy*. T. D. was so named by Romberg of Berlin; but Dr. Todd of London in 1847 first recognized its true nature, and specially insisted on the distinctions to be drawn between T. D. and *Paraplegia* (see PARALYSIS). The name of *locomotor ataxy* was first applied to the affection by Dr. Duchenne of Paris. It is characterized by a want of power in harmonizing the action of certain muscles, the absence of such coordinating power being first apparent in the lower extremities, and the gait in consequence being straggling and unsteady. True paralysis is absent, but sensitiveness is diminished, and neuralgic pains are present in the legs and feet. The loss of power progresses, and the later stages of the malady are marked by such symptoms as disordered vision, incontinence of urine, and exhaustion. The duration of this disease varies. It may run its course in a few months, or be prolonged over years. The *etiology* or *causes* of T. D. are still obscure. Mr. Lockhart Clarke has shown that a peculiar change in the posterior columns of the spinal cord, and in the posterior or sensory roots of the spinal nerves, accompanies this disease. Prolonged exposure to cold and damp, drunkenness, sexual excesses, masturbation, and like causes have been credited with inducing the disease. It is alleged to be more common in males than in females, and subjects between the ages of 30 and 50 are said to suffer most frequently from its attack.

The characteristic movements in T. D. are worthy of note. The patient has an unsteady gait, and walks like a drunken person, but soon recovers his bearing in some degree. A difficulty in carrying out the intents of the will is experienced, and in picking up an object one hand is employed to steady the other. When the eyes are shut, the patient walks with extreme difficulty. T. D. may be distinguished from disease of the cerebellum by the absence of the characteristic pain at the back of the head, and vomiting. The *prognosis* of T. D. is very unfavorable. Its progress may be retarded, but the prospect of ultimate cure is well-nigh hopeless. The *treatment*, as may readily be understood, is limited to the improvement of the general health, rather than to any specific remedies. Warm clothing, nutritious food, and rest are the chief items in the course of treatment prescribed for this disease; whilst opiates are indicated for the relief of the neuralgic pains. Sulphur baths have been prescribed in the earlier stages to relieve the numbness, and attention requires to be paid to the bowels with a view of alleviating constipation.

TABINE'T, a rich kind of cloth, chiefly used for window-curtains. It consists of a warp of silk and a weft of wool-yarn, of the same kind as that used in making poplin. It has the appearance of a fine damask, and is usually enriched with diaper patterns.

TABLEAUX VIVANTS (i. e., Living Pictures), representations of works of painting and sculpture, or of scenes from history or fiction, by living persons. They are said to have been invented by Madame de Genlis, when she had charge of the education of the children of the Duke of Orleans. They have long been common in theaters, and have more recently become an amusement of private circles. In an æsthetic point of view, they are of no value whatever, but rather are of injurious influence, and contrary to just principles of taste.

TABLE-LANDS, or PLATEAUX, are extensive plains at a considerable elevation above the sea, whose boundaries are either ranges of mountains much higher on the side away from, than on the side next to, the table-lands; or steep acclivities, sloping from the level of the plateaux to the surrounding country. They are often traversed by mountain chains, and occasionally even lose the character of plains altogether, being mere conglomerations of hills. The chief table-lands are in Europe, Central Spain; in America, the Oregon territory, the great salt plain of Utah, the north and center of Brazil; in Africa, the interior of Barbary; while in Asia, almost the whole of the south and center of the continent consists of plateaux, which rise terrace above terrace till they culminate in that of Tibet. Of the Asiatic plateaux, the principal are: that of Asia Minor (3280 feet above sea-level), Armenia (7000 feet), Persia or Iran (3000 feet), Mysore (4000—5000 feet), Deccan (1500—2000 feet), Tibet (12,000—17,000 feet), and Chinese Tartary (3000—4300 feet). These table-lands are generelly accounted for by the supposition of a more extensive and uniform action of the upheaving force than that which produced mountains; and satisfactory indications of the former action being quite recent, and long subsequent to the latter, are occasionally discovered.

TABLE-MONEY is an allowance granted to general-officers in the army, and flag-officers in the navy, to enable them to fulfil the duties of hospitality within their respective commands. It

varies according to the locality or importance of the appointment, £3, 3s. a day being the maximum, except under very unusual circumstances.

TABLE MOUNT. See CAPE TOWN.

TABLES, LUNAR, are tabular lists of the values of the elements of the moon's orbit, as planetary tables are those of the elements of the planets' paths; but the term is also occasionally employed to denote the tabulated angular distances of the moon from certain stars at fixed epochs, as given in the *Nautical Almanac* (q. v.). See LATITUDE.

TABLE-TURNING. See ANIMAL MAGNETISM; SPIRITUALISM.

TA'BOR, a celebrated mountain of Northern Palestine, rising solitarily in the north-eastern part of the plain of Esdraëlon, to about the height of 1000 feet, and commanding the most extensive and probably the most magnificent prospect in the Holy Land. Eastward, the eye catches a gleam of the waters of the Galilean Sea, 15 miles distant; while the whole picturesque outline of its deep-sunken basin, of the rolling trans-Jordanic plateau, and the course of the sacred river itself, is clearly traceable; westward stretch away into the dim horizon the rich plains of Galilee, rising up into the dark-green ridges of Carmel, overhanging the Levant; on the north and north-east, the snow-covered heights of Hermon (see LEBANON) glitter pale over the intervening hills; while to the south, the view embraces the fatal heights of Gilboa and the confused landscapes of Samaria. T. itself is at present thickly clad with forests of oak, pistacias, &c., the haunt of wolves, wild-boars, lynxes, and various kinds of reptiles. Its beauty alone would be sufficient to insure it distinguished mention among the mountains of Palestine, but it owes its celebrity even more to its having been regarded from an early period as the Mount of Transfiguration. This opinion, however, is now all but universally abandoned, as there is strong evidence of its summit having been then occupied by a city; and travelers are disposed to look for the scene of this supernatural incident further north, in the neighborhood of Hermon. In the times of the Crusaders, T. was studded with churches and monasteries, relics of which, as well as of Roman and Saracenic structures, still remain.

TA'BORITES (a sect of the Hussites in Bohemia) derived their name from their fortress of Tabor, near the river Luschnitz, an affluent of the Moldau, 49 miles south-south-east of Prague. There is now a small town at the place, which has a pop. of 6717, and carries on some woollen manufactures, &c.—The first leader of the T. was John Ziska (q. v.) of Trocynow. Under him was Nicolas von Hussinecz, who repelled the imperial army from Tabor in 1420. The Calixtines, desirous of the peace of the country, offered the throne of Bohemia first to King Ladislas of Poland, then to the Grand Duke Witold of Lithuania, and afterwards to his brother Coribut. Ziska refused his consent, and thus these parties became completely separated. In the years 1420 and 1421, both of them set forth their creed in a number of articles. The T. absolutely rejected all ordinances of the church not expressly appointed in the Holy Scriptures. Both parties were united by common danger in opposition to a common enemy. In 1422, Ziska defeated the Imperialists at Deutschbrot, and thereafter with uninterrupted success in a number of minor conflicts; and in 1424, Prague was saved from destruction only by submitting to hard terms of peace.

After Ziska's death, Procop (q. v.) the Greater, or Procop Rasa (the Shaver), and Procop the Less were their leaders. In 1427 and 1431, they gained great victories at Miess and Tachau over the mercenary crusaders of the German Empire, and till 1432 their incursions were the dread of the neighboring countries. The Council of Basel, finding them still unconquered in 1433, proceeded to treat with them; and the Calixtines entered into an arrangement, known as the *Prague Compact*, which, however, was despised by the T. and the Orphans, as that section of the T. who considered Ziska as irreplaceable, had come to be termed. The T. and Orphans were completely defeated at Böhmischbrot on May 30, 1434, by the now united forces of the Roman Catholics and the Calixtines. In the treaty of Iglau, in 1436, the Emperor Sigismund confirmed the compact, and promised religious and political liberty. The civil war, however, continued till King Ladislas in the Diet at Kuttenberg, in 1485, established a religious peace, securing both Roman Catholics and Calixtines in their possessions. The T. were eventually lost in the sect of Bohemian Brethren (q. v.) which arose from amongst them.

TA'BOUR, a small drum, played with one stick, in combination with a fife. It was formerly used in war, but has now given place to the kettle-drum.

TABRI'Z (pronounced and frequently written *Tabreez*), a great and ancient city of Persia, capital of the province of Azerbijan, 40 miles east of Lake Urumiah, and on the Aji, which flows south-west into that lake. The town is surrounded by a ditch and a brick wall, pierced by 7 gates. It forms an oblong of gardens and houses, 2¼ miles long; stands 4000 feet above sea-level, but nevertheless has the appearance of being shut in by mountains. The streets are broader and cleaner than in most eastern cities, but they are flanked as usual by the pits from which the earth required for their houses was taken; the houses are infested with noxious insects; and the bazaars are roofed with sticks, and are dark and dirty. Water, however, is comparatively plentiful. The chief buildings of T. are not specially striking. Perhaps the principal architectural feature of the town is the fine ruin, Kabúd Masjid, or 'blue mosque,' about 300 years old, and in part covered with blue tiles beautifully arabesqued. The citadel is a spacious edifice of burned brick, the walls of which, however, have been cracked in many places by earthquakes.

T. is the seat of a varied industry, in which leather and silk manufactures and gold and silver smith's work alone are of importance; recently it has also become the emporium of an extensive trade, the exact value of which, however, is not known, owing to the careless manner in which the custom-house officials transact their business, and to the prevalence of smuggling. Merchandise, to the value of £400,000, is exported through the regular channels from T. to Russia; but it is estimated that, in 1859, a quantity of equal value was conveyed to that country by smugglers. Since 1859, this illicit traffic has very much diminished, although it still exists along the whole Russo-Persian frontier of Azerbijan. The chief imports are cotton fabrics, sugar, woollen cloth, and wines and spirits. The chief exports are cotton cloths (originally from England), drugs and spices, dried fruits, shawls, carpets, and raw silk. The commerce of 1877–8 was very small, mainly on account of the Russo Turkish war, which arrested the trade between Trebizond and T. The imports were in that year valued at £525,500, the exports at only £270,000; while in 1873–4 the collective trade amounted to over £7,100,000. The Anglo-Indian telegraph line passes through the city.

T., the ancient *Tauris*, became the capital of Tiridates III., king of Armenia, in 297 A.D., and was probably at that time an old city. In 791 A.D., it was enlarged and greatly embellished by Zobaidah, the wife of Harûn-al-Rashid. In 858, aad again in 1041, the city was devastated by an earthquake. It was taken and sacked by Timur in 1392, and was soon after seized by the Turkomans, from whom it was taken by the Persians in 1500. In 1721, it was again visited by a dreadful earthquake, and on this occasion 80,000 persons are said to have perished. It has been several times in the hands of the Turks, but was finally taken from them by Nadir Shah in 1730. T. is a city of Turks, and Turkish is the language spoken. Pop. variously estimated at 110,000—180,000.—Eastwick's *Three Years' Residence in Persia* (Lond. 1864), and *Commercial Reports from Her Majesty's Consuls* (1878).

TA'BU, TAPU, or TAMBU, a Polynesian term, denoting an institution found everywhere, and always essentially the same, in the Polynesian islands and in New Zealand. Its primary meanings seem to be exactly the same as those of the Hebrew *to'ebah*. This word, like the Greek *anathema*, the Latin *sacer*, and the French *sacre* (and the corresponding and similar terms in most languages), has a double meaning—a good sense and a bad; it signifies on the one hand, sacred, consecrated; on the other hand, accursed, abominable, unholy. It results from a thing being held sacred, that certain acts are forbidden with reference to it, and from any act being deemed abominable, that it is forbidden; a notion of prohibition thus attaches to the word tabu, and this is, in many cases, the most prominent notion connected with it. The term is often used substantively in the sense of a prohibition, a prohibitory commandment. If a burial-ground has been consecrated, it is tabu; to fight in it is then an act sacrilegious and prohibited, and this also is tabu; moreover, those persons are tabu who have violated its sanctity by fighting in it, and they are, loosely and popularly, said to have broken the tabu. This example illustrates all the uses of the word. It has furnished to the English language the now familiar phrase of being 'tabooed' = forbidden.

The extent to which, among the Polynesians and New Zealanders, things and acts are tabu, must appear almost incredible to Europeans unaware of the facts of savage life. Without much detail, it is impossible to convey any idea of it. The prohibitions, however, divide into two classes: one consisting of traditional rules, binding upon all, acting through religious terror equally upon chiefs and people; the other, of prohibitions imposed from time to time, obviously with the view of maintaining or extending the authority of the chiefs. Those of the first class are by far the most remarkable. Of the most important of them—those bearing upon what are called sacred things, those relating to the person of the chief, and those relating to intercourse between relatives—a few examples may be given.

Any house or piece of ground consecrated to a god is tabu; and thus affords an inviolable shelter to men fleeing from an enemy. *A fortiori*, all temples are tabu. To sit upon or to touch the threshold of a temple, is tabu to all except chiefs of the first order; the

lesser chiefs may stride over the threshold, but common persons pass over it on their hands and knees. It is tabu to eat the plant or animal believed to be the shrine of one's tutelary god. To come in the way of a funeral procession is severely tabu, for it is believed that the gods accompany the procession; if any person were to disregard the warning chant of the mourners, they would rush at him and put him to death. Again, to touch the person of a chief, is tabu to his inferiors; also, to touch anything belonging to him, to eat in his presence, to eat anything he has touched, or to mention his name. And a chief's threshold is as sacred as that of a temple, and must be passed over in the same manner.

It is strictly tabu to touch a dead chief or anything which belonged to him, or any of the clothes or utensils employed in his interment; even those employed in laying out the body pay the penalty of infringing this prohibition. The interdict upon family intercourse varies in extent in different places. In the Tonga Islands, it was tabu to mention the name of father, mother, father-in-law, mother-in-law; also to touch these relatives, to eat in their presence (unless with the back turned, when constructively the person was not in their presence), or to eat anything which they had touched. In the Fiji Islands, generally, it is tabu for brother and sister, first-cousins, father-in-law and son-in-law, mother-in-law and daughter-in-law, brother-in-law and sister-in-law, to speak together, or to eat from the same dish. Husband and wife, too, are forbidden to eat from the same dish. In some places, a father may not speak to his son after he has passed his 15th year. In an immense number of cases, equally extraordinary, the tabu is used to enforce the prevailing ideas of social propriety. It interferes with cooking, eating, dressing, speaking: scarcely anything is too minute to be regulated by it.

The traditional tabu also supplies to some extent the place of laws and a police. In many places, exposed property of some kinds is always under its shelter. In some cases, it appears to have been worked in the interest of the priests; thus, certain foods—for example, turtle—are always tabu, and cannot be eaten until a portion has been set aside for the gods. There is a purely superstitious use of it, too, in relation to common things, as when a canoe is made tabu that it may go more safely.

The chiefs have a large discretionary power of declaring articles or actions tabu; indeed, their power is unlimited, but they are expected to keep within precedent. In many cases, they use it for purely public purposes—thus, when a feast is coming on, they lay a tabu upon pigs and nuts, and other articles, that there may be abundance for the feast. And when a scarcity of anything is apprehended, they place a temporary tabu on its use. Speaking generally, any article of food—fish, flesh, fowl, grain, or fruit—may be rendered tabu. A coast, a river, a hunting-ground, may be declared tabu; and then there is an end of fishing, and sailing, and hunting, until the chief has withdrawn the prohibition. The tabu is obviously a powerful instrument of government; and the chiefs are very adroit in using it for their own advantage.

When a man has accidentally infringed the tabu against touching a chief, or a relative, or things immediately connected with him, he is freed from the state of tabu by a ceremony called *moëmoë;* this consists in pressing, first the palms, then the back of the hands, to a superior chief's foot, and afterwards washing the hands with water. If a man has accidentally eaten food which a relative or chief has left, he goes through a ceremony called *Fota,* which consists in pressing a superior chief's foot against the stomach. Any breach of the laws relating to sacred places, must be atoned for by sacrificing to the offended god. A person, when he is tabu, must not use his hands in feeding himself or in working; were he to feed himself, it is believed that he would die; he must be fed by others until the tabu is removed. In many cases, the tabu can only be removed by time. Thus, a common person, who has touched a dead chief, remains tabu for ten lunar months; a chief for four or five months, more or less, according to the deceased's superiority over him. In several cases, breach of tabu is punished with death; in many, it involves a sort of outlawry—the neighbors of the offender being free to carry off or to destroy his goods.

It is obvious that the effect of breaking a tabu—at any rate, one effect of it—is to produce uncleanness. The offender has done someting unholy, accursed; his hands are not clean; if he has not sinned in the last degree, he must make atonement or undergo purification. The chief, holding a divinely appointed rank, recognized as a semi-divine person, descended from the gods, is the medium of purification; he has authority to loose as well as to bind. The offence consists in a thing having been done displeasing to the supernatural powers, for which, it is believed, they will not fail to take vengeance. It is not, in the general case, an offence against any particular god; nor is the punishment of it looked for from one god more than from another. Tabu is certainly older than most of the Polynesian gods; it must have existed for ages before the mythologies took their present shapes; it might have existed before any name for god had become current. It has no connection with fetishism. The Polynesians do not worship natural objects; their belief that certain plants and animals are the shrines of gods, would naturally lead to the worship of those; but in fact, they merely do not eat the plant or animal which is the shrine of their tutelary god. And though this is enforced by a tabu, the tabu is evidently distinct from the belief in the god's connection with the plant or animal; it is only the means of enforcing that belief—being the customary means used to prevent any act which would provoke a god to anger.

The origin of tabu seems to be a vague fear of superhuman powers; this has become associated with certain things and acts; thus practically, tabu is a system of divinely appointed restraints—religion, in the primary sense of the word. The religious horror has attached itself—or, through the policy of priests and rulers, has become attached—to every prohibition supported by a strong expediency; which it is apt to do among rude peoples, especially where the prohibition relates to the family, or to the relation of tribesmen to their chief. It must have been through a long process of construction, carried on by the governing classes—the chiefs and the priests—that tabu became the system it now is. The extensive political application of tabu is sufficient evidence that the Polynesian chiefs have been adepts in the art of turning the religious feelings of their countrymen to their own account.

TACAHOUT is the name given, in Algiers, by the Arabs to the small gall formed on the Tamarisk tree, *Tamariscus Indica.* Since the discovery of photography, these galls have become of considerable importance as a source of gallic acid, of which they contain a large proportion. The French chemists import considerable quantities; and the same gall, under the name of Mahee, is imported for the same purpose by British chemists from India.

TA'CAMAHAC, or TACAMAHA'CA, a name which, from the number of its applications, has produced considerable confusion in the history of commercial products. No less than four different resins are known under this designation. One, from Mauritius, is obtained from a tree common in India and its islands, called the Poon-wood Tree, *Calophyllum inophyllum.* Another, from South America and the West Indies, is obtained from *Zanthoxylum* (*Fagara*) *octandra*—this is usually called Shell Tacamahac. A third, also from South America, is yielded by a tree called *Icica tacamahaca;* it is supposed to be the Mexican Copel. And the fourth is from North America, and is the produce of the Carolina or Tacamahac Poplar; it is collected in small quantities, and has only a small value for supposed medicinal properties. The others are chiefly used for varnishes.

TA'CCA, a genus of plants of a small natural order called *Taccaceæ,* nearly allied to *Araceæ.* They are large perennials with tuberous roots. The species are few, and are found in maritime places and woods in the South Sea Islands and the warmest parts of Asia and Africa. Some of them (*T. pinnatifida,* &c.) are much cultivated for the sake of their tubers, which are used as an article of food, although they are acrid, and require maceration in water to remove their acridity, on account of which also they are generally eaten with vinegar, or some acid substance. They contain a large quantity of starch, which is wholesome and nutritious, and is imported into Britain as a substitute for West Indian arrow-root. It is known as *Tahiti Arrow-root.* Dr. Seemann says that it is an effectual cure for dysentery, which other arrow-root is not.—The boiled leaf-stalks of the plants of this genus are also used in China and Cochin-China as an article of food.

TA'CIT RELOCA'TION, in the Law of Scotland, is a phrase borrowed from the Roman law, signifying that when a tenant continues in possession of the lands after his lease or term has ended, there is an implied or tacit renewal of the lease, whereby he continues bound to pay the same rent and observe the same stipulations.—The same doctrine exists in English law, though the above phrase is not used.

TACITU'RNITY, in the Law of Scotland, is a mode of extinguishing an obligation by mere silence, and making no claim upon it within a long time. It is a distinct ground, and embraces a shorter period than the ordinary prescription or Limitation (q. v.); for if a creditor never apply for payment or performance of the obligation, a presumption arises either that there never was such an obligation, or that he has abandoned it. Much depends on the circumstances of each case whether such a doctrine is applicable; and, as a general rule, the periods of prescription are adopted as superseding the common law doctrine of taciturnity.

TA'CITUS, Caius Cornelius, the historian. Of his parentage, or of the time and place of his birth, we can only conjecture that his father was probably Cornelius Tacitus, a Roman eques, who is mentioned as a procurator in Gallia Belgica, and who died in 79. From the emperors Vespasian, Titus, and Domitian, he received promotion and other marks of favor; and in 78, he married the daughter of Caius Julius Agricola. In 88, when Domitian was emperor, and T. prætor, he assisted as one of the quindecemviri at the celebration of the *Ludi seculares.* Agricola died in Rome in 83, while T. and his wife were absent; and noth-

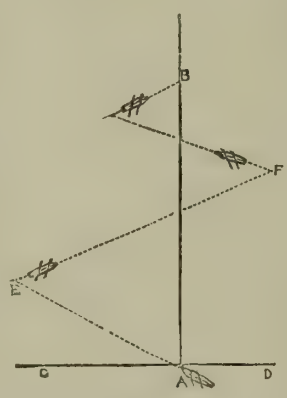
ing further is known of the historian till 97, when, in the reign of Nerva, he was appointed consul suffectus, succeeding T. Virginius Rufus, whose funeral oration he delivered.

T. had already attained distinction as an orator when the younger Pliny was entering upon public life; and both of them were appointed, in Nerva's reign, in 99, to conduct the prosecution of Marius, then proconsul of Africa. T. became one of the most intimate friends of Pliny, of whose letters 11 are addressed to him. The time of T.'s death is unknown, but he most probably survived Trajan, who died in 117. His extant works are: (1) *Vita Agricolæ*, written after the death of Domitian in 96, and universally admired as a masterpiece of noble sentiment and pregnant epigram. (2) *Historiæ*, written after Nerva's death in 98, and before the *Annales*, and embracing the period from the second consulship of Galba in 68 to the death of Domitian in 96. Only the first four books have reached us in a perfect state, but there must have been many more. (3) *Annales*, commencing with the death of Augustus in 14, and closing with the death of Nero in 68. These also have reached us only in an imperfect state. (4) *De Moribus et Populis Germaniæ*. This treatise is trustworthy only as regards those Germans who were best known to the Romans from their proximity to the Rhine. For the provinces beyond that river, it has no value, whether geographical or political. (5) *Dialogus de Oratoribus*, if the work of T. at all, must be his earliest. T. is one of the greatest of historians. In love of truth and integrity of purpose, he is equalled by few; in conciseness of phrase and power of saying much and implying more in one or two strokes of expression, he is rivaled by none. The best editions are those of Orelli and Halm.

TACK, the Scottish law-term synonymous with Lease (q. v.).

TACK, TACKING. The *tack of a sail* is the lower windward corner. The *tack* is the rope employed in hauling down that corner to its proper position. The *tack* of a fore-and-aft sail is its lower forward clue or corner; it also designates the rope for hauling down that corner. A ship is said to be on the *starboard* or *port tack* when she is close-hauled with the wind on the starboard or port side.

Tacking is the practice of beating up against an adverse wind by a zigzag course. If a vessel at A require to sail due north to B, and if the wind be either north, or from any point north of the line CAD, it is obvious that the wind will not carry her directly to her destination. As an extreme case, let the wind be north, or dead against her. By setting her sails obliquely, as at A, it will be possible to beat up in the direction AE. If the master consider that at E he has passed sufficiently from his straight course to B, he will then put his helm a-lee, which brings the ship's head straight to the wind, the tacks of the sails being at the same time set free. The after-sails are then smartly braced over to the opposite side, and the ship's head falls off from the wind in an opposite direction to that previously held, until the course is EF. This process is repeated on each side of the line AB, until at length the ship makes her port, B. The length of each tack, as EF, is called a *board*.



When the wind is straight ahead, as in the above example, the several boards should obviously be equally on each side of the line AB. If, however, the wind were not so direct, it would be necessary that the boards in one direction should be shorter than those in the other. Sometimes, from the nature of the channel, as an estuary, &c., it is necessary to take a long tack one way, say to starboard, and a very short one to port. This is known as 'sailing with a long and a short leg.'

TACKING OF MORTGAGES, in the Law of England, is a practice that sometimes occurs in the course of mortgage securities, when one person acquires more than one mortgage over the same estate. Thus, though mortgages, according to the general rule, rank according to the order of date, yet, if a third mortgagee, who became so without notice of a second incumbrance, purchase the first mortgage even after notice of the second mortgage, so as to acquire a legal title, and if he holds them both in his own right, he can tack the one to the other, and so obtain priority for the third mortgage over the second mortgage. This is on account of an old technicality, scarcely intelligible to other than lawyers.

TACO'NIC SYSTEM, an extensive series of rocks in the United States, described by Dr. Emmonds. They consist of two divisions, the Upper having a thickness of 25,000 feet, and containing Lower Silurian fossils; and the Lower, with 5000 feet of thickness, in which, as yet, no fossils have been found, but which is generally considered to be the equivalent of the Cambrian rocks of Britain.

TA'CTICS, MILITARY. Strategy (q. v.) is the art of manœuvring armies with reference to the objects of the whole campaign—the securing of communications, the cutting off an enemy from his base, throwing him into a position where he must fight at a disadvantage, or surrender, &c. Tactics has regard to the evolutions of an army in the actual presence of an enemy. It is the strategy of the battle-field; the science of manœuvring and combining those military units which drill, discipline, and the regimental system have brought to the perfection of machines. It was admirably described by Napoleon as *the art of being the stronger*—that is, of bringing an overwhelming force to bear on any given point, whatever may be the relative strength of the entire armies opposed.

The earliest records of battles are those of mere single combats, in which the chiefs, fighting either on foot or in chariots, performed great deeds; and the commonalty, who apparently were without discipline, were held in profound contempt. With the growth of democracy arose the organization of the Phalanx (q. v.), the advance of which was irresistible; and its firmness equally so, if charged in front. It, however, changed front with great difficulty; was much deranged by broken ground; and failed entirely in a pursuit, or if attacked in flank. Far lighter, and more mobile, was the Roman Legion (q. v.). Among Roman tactics was also the admirable intrenchment, which they scarcely ever omitted as an additional source of strength for their position.

'Events reproduce themselves in cycles;' and with the decay of Roman civilization came again the mail-clad heroes and cavaliers—mounted this time on horses—who monopolized the honors of battle, while the undisciplined footmen had an undue share of the dangers. Later in the feudal period, this disparity between knight and footmen was diminished by the employment of bodies of archers, whose shafts carried distant death. The adoption of gunpowder for small-arms altogether neutralized the superiority of the armored knight. This change brought infantry into the front place in battle, and threw cavalry into the status of an auxiliary.

The French revolutionary wars tended much to the development of artillery as a field-weapon, and Napoleon employed this terrible engine to its fullest extent, a practice followed by the best modern generals, who never risk a man where a cannon-ball can do the work. Frederick the Great was considered an innovator for fighting with infantry four deep. During the French War, the formation of three deep became general, and still obtains in several European armies. Before the battle of Waterloo, the British leaders had acquired sufficient confidence in their troops to marshal them in a double line. It is doubtful whether the advance in arms of precision will not soon necessitate the formation in a single line, or even in a single line in open order.

It is impossible, in an elementary article of this character, to give even an approach to an essay on modern tactics, which is an intricate science. We can only notice briefly a few of the more important principles.

First, as to the art of being the stronger, which is undoubtedly the highest recommendation in a general, we may cite the example of the battle of Rivoli. In 1796, Napoleon was besieging Mantua with a small force, while a very much smaller army operated as an army of observation. The Austrian commander had collected at Trent a force powerful enough to crush completely the French army, with which he was marching south. Parallel with his course lay the Lake of Garda, and to prevent the enemy escaping up one side, as he marched down the other, the Austrian leader divided his army into two powerful corps, and marched one down each side of the lake. The instant the young French general knew of this division, he abandoned the siege of Mantua, collected every available man, and marched against one body of the enemy. Though far inferior on the whole, he was thus superior at the point of attack, and the victory of Rivoli decided virtually the whole campaign. This corresponded in principle with Napoleon's general plan in battle. He formed his attack into column, tried to break through the center of the enemy's line; and if he succeeded, then doubled back to one side, so as to concentrate the whole of his own force against one half of the enemy's, which was usually routed before the other half of the line could come up to the rescue.

Taken collectively, the tactics of the three arms may be thus summarized: The infantry form the line of battle, and probably decide the day by a general advance over the enemy's ground. The cavalry seek to break the opposing infantry by frequent charges in front, or on any flank which may be left exposed. If a part of the line wavers, a charge of horse should complete the disarray. When the rout commences, the cavalry should turn it by furious onslaught into utter discomfiture. The province of the artillery is to cannonade any portion of the line where men are massed, or where a charge is about to be made; to demoralize cav-

alry, and generally to carry destruction wherever it can best disconcert the enemy.

Adverting now very briefly to the tactics of the several arms individually, we have—

Infantry.—This force has four formations—skirmishers, line, column, and square. The skirmishers precede and flank an advancing line or column, picking off the enemy, whose masses offer good mark, while their own extended order gives them comparative impunity. If resistance be encountered in force, the skirmishers retreat behind their massed supports. The line is a double or treble line of men, firing or charging. For musketry purposes, it is the most formidable formation, and is the favorite British tactic in every case where the officers can depend on the steadiness of their men. For bursting through a line, the deep column is the most effective. It is the favorite French formation, and during the Revolutionary and Napoleonic wars, the British and Russians alone succeeded in resisting it.

At Vimiera, the 50th Regiment, 700 strong, stood in line: it was attacked by a column of 2000 French. The English colonel threw back his left (which was the end attacked), and advanced his right, delivered a volly at point-blank range, charged the column in flank, and utterly routed it before the French could deploy into line to resist the onslaught. The column is therefore the best formation on a march; the line when in actual collision with the enemy. The formation in Echelon (q. v.) to a great extent combines these advantages. See SQUARE.

Cavalry.—The function of heavy cavalry is limited to the charge in line. The light cavalry form in small sections, to scour the country, collect supplies, and cut off stragglers.

Artillery.—No distinct tactics exist for this arm beyond the fact, that a concentrated fire is vastly the most effective, and that the artillery should always have a support of infantry at hand, to protect it from a sudden incursion of hostile cavalry.

Tactics of position depend on the moral energy of the commander-in-chief. Few would dare, as Cæsar did, an invasion in which there was no retreat, if defeated. It is a military maxim not to fight with the rear on a river, unless many bridges be provided for retreat, in case of disaster. A convex front is better than a concave front, because internal communication is more easy. The flank should be protected by cavalry, or preferably by natural obstacles. In battle, a long march from one position to another, which exposes the flank to the enemy, is a fatal error. By such, the French won Austerlitz, and lost Talavera. In a pursuit, a parallel line is better than the immediate route the retreating enemy has taken, as supplies will be more readily procured, and he may by celerity be attacked in flank. This was strikingly exemplified in the Russian pursuit of Napoleon's army retreating from Moscow.

TACTICS, NAVAL. With the advent of steam, iron-plated ships, and rams, the tactics under which Rodney and Nelson fought and conquered have passed away, while the principles of the new warfare have scarcely been sufficiently established for reduction to theory. A glance at the obsolete tactics of bygone times must therefore suffice in the present article.

In ancient naval engagements, where the vessels fought on the comparatively smooth waters of the Mediterranean, and where the use of oars rendered the commanders nearly independent of the wind, the attack consisted of a charge with the beaked prows, followed, if that failed, by the use of balistæ and a hand-to-hand struggle. See NAVIES, ANCIENT. The introduction of gunpowder, with broadside ordnance, necessitated a change, and the great desideratum of each admiral was to present as long a line of broadsides as possible to the enemy, to take care that none of his ships was masked by the intervention of another between it and the foe, and to endeavor in each ship to oppose its broadside to the bow or stern of a hostile ship, so as to obtain the preponderance of force, and to rake his decks. The ships of two decks and upwards formed the line of battle, while frigates and smaller vessels served as look-outs and skirmishers. A fleet in one line would, however, have been of inconvenient length for sailing, and it was usual to sail in three, six, or nine parallel lines while traversing the ocean, the ships of the rear lines tacking into their places in the line of battle on the signal to form for action. The great principle of manœuvring was to get the weather-gage, i. e., to be to windward of the enemy, both for facility of navigation, and because the smoke would inconvenience him most. The standing attempt during the French war was to double the enemy's line (see CLERK, JOHN, of Eldin), by piercing it, or passing it at the van or rear, and then, by tacking in its rear, to place his ships between two fires. This was first practised in Lord Rodney's action of 1782, and was successfully repeated by Nelson at the battle of the Nile.

Under steam, and with ships carrying colossal ordnance, naval tactics have entirely changed. It used to be the object to avoid being raked; it is now to avoid being hit at all. The projectiles used are so tremendous that a few hits involve destruction. Ships are consequently constructed so as to offer the least mark to ordnance; and with the same view, they are kept constantly in rapid motion. Actions are fought, not, as in old time, within pistol-shot, but at a mile or two miles' distance. The loss of life is less; for the battle is no longer decided hand to hand by the cutlass and the boarding-pike, following a furious cannonade; but after a few long shots with ponderous missiles, one or other vessel becomes disabled, and being helpless, yields the victory to her foe. The ships will be steamed end on if they act as rams, and also to offer less mark to shot. Rival fleets have never yet met on a large scale to fight under the conditions of modern war.

TADEMA, LAWRENCE ALMA, a distinguished painter, born 8th January 1836, at Dronryp in the Netherlands. He was educated at Antwerp, but early settled in London, where he was naturalized as an English subject in 1873. His numerous and very popular paintings deal chiefly with antique classical and Egyptian subjects, which, under T.'s handling, have a very vivid air of reality. 'How they amused themselves in Egypt 3000 years ago' (1863), is one of T.'s earlier paintings; 'Cleopatra' (1882), one of his last. T. is an R.A., a member of various foreign academies, a chevalier of the Legion of Honor, &c. There was an exhibition of T.'s pictures in the Grosvenor Gallery in 1882.

TA'DMOR. See PALMYRA.

TA'DPOLE. See FROG.

TAEL, a money of account in China, is equivalent to about 6s. 8d. sterling, or to a thousand of their sole coin, the 'tsëen,' tchen, or 'cash.'

TÆNIA AND TÆNIADÆ. See TAPEWORM.

TAE-PINGS, the name given to the Chinese rebels who made their appearance in 1850, and (see CHINESE EMPIRE) desolated some of the best cultivated provinces of China. After the war of 1860, it became the interest of the English, French, and American governments to re-establish order in China. The repulse of the rebels at Shanghai in August 1860 had been followed by several engagements between them and the imperialists, in which the T. were defeated, mainly in consequence of the re-organization of the imperial army by Ward, an American. In the beginning of 1862 the T. again advanced on Shanghai, and were twice defeated. In that year Ward was killed; and 'Ward's force,' handed over to an English officer, took the name of Gordon's brigade. Permission was also granted to Captain Sherard Osborne to organize in England a small fleet of gun-boats, to ascend the Chinese rivers and re-establish order. Gordon's brigade rendered essential service to the imperial government. The rebels were defeated in upwards of 16 engagements; and in 1864, almost every important city was taken from them. Captain Sherard Osborne's expedition was less successful. He found that the jealousy of the Chinese officials would not permit him to take the steps necessary to discharge properly the duty he had undertaken, and he therefore threw up his commission, and returned to England.

The conduct of the imperial authorities at Su-chow, where a horrible massacre took place, led to the withdrawal of the English military force: but the rebellion had been effectually checked. They were finally dispersed in April 1865, when they were routed by the imperial army at Kia-ying-chou in Kwan-tung. In the same year, the Nienfei, or marauders of the north, began to be troublesome. This was a marauding expedition, without political significance, organized by restless spirits among farmers who had been ruined by the overflowing of the Yellow River, the repair of the embankments of which had been neglected on account of the confusion and expense of the Tae-ping rebellion. The last show of active warfare made by a body of Nienfei was in the beginning of 1866, when, joined by some imperialist regiments whose pay was in arrear, they threatened Hankow; and would have attacked the European Settlement but for the arrival of some English gun-boats. The malcontent imperialists were easily brought back to allegiance, and the marauders were dispersed, and have not been authentically heard of since.

The Mohammedans of the north-west of China give the imperial government trouble from time to time. Their risings are often on political grounds, and they are on this account apt to be confounded with the annihilated Tae-pings. See PANTHAYS.

TA'FFETY (or Taffeta), a term of somewhat general application in silk-mercery. It was formerly applied to all plain silks simply woven by regular alternations of the warp and weft, and is by some writers supposed to be the first kind of silk-weaving known even to the Chinese, from whom it came to us. Modifications have, however, been introduced, by varying the quality of the warp and weft, and by the substitution of various colors for the single one of the original taffety. It has therefore become a sort of generic term for *Plain Silk*, Gros de Naples, Gros des Indes, Shot or Chameleon silk, Glacé, and many others, and even for some combinations of silk, wool, and other materials.

TAFFRAIL, in a Ship, is the rail over the heads of the stern-timbers, extending across the stern from one quarter-stanchion to another.

TA'FIA, a name used in the sugar-producing colonies for a kind of rum distilled from molasses. The term is only in general use in French colonies.

TAFILELE'T (or Tafilelt), one of the four territorial divisions of Morocco (q. v.).

TAGANRO'G, an important seaport of Russia, in the gov. of Ekaterinoslav, on the N. shore of the Sea of Azov, 20 m. N.-W. of the chief mouth of the Don. It was founded by Peter the Great in 1696, was lost to Russia from 1712 till 1774, when it again reverted to the people who founded it, and since that time it has increased in importance yearly. The port of T. is so shallow that large ships cannot approach within half a mile of the quay, and at this distance from shore they load and unload by the help of barges. The harbor is wholly unprotected. Owing to its position on the shore of a very fertile country, it is able to export wheat in large quantities (1,050,156 quarters being exported in 1872), as well as linseed, hempseed, skins, wool, butter, iron, copper, and Russian leather. Of these articles, the last four are obtained from the governments of Perm and Orenburg. The imports are mainly wine, machinery and agricultural implements, tea, fruits, and porter. While the exports have an annual value of about £5,000,000, the value of the imports does not exceed £2,000,000. There are two fairs yearly, and fishery is diligently prosecuted. T., which enjoys a remarkably fine climate, has many handsome public buildings. Pop. (1878) 48,186.

TAGLIONI, MARIE, a celebrated *danseuse*, born at Stockholm, 23d April 1809, of Italian parents, her father (Filipo T., born at Milan, 1777) having been successively ballet-master at several opera-houses in different parts of the continent. Mademoiselle T. made her début in Paris in 1827, where she created a perfect *furor*, and was at once recognized as the first of ballet-dancers. Her success was equally great at most of the other European capitals, London included. She retired from the stage in 1847, and afterwards resided in Italy and in London, where she taught dancing and deportment.

TA'GUS (Span. *Tajo*), the largest river of the Spanish peninsula, rises on the frontier of New Castile and Aragon, between the Sierra de Albarracin and the Sierra de Molina, about 45 miles north-east of the city of Cuenca. It first flows north-west for about 30 miles to its union with the Gallo, at which point it curves to the south-west, and flows in that direction to Toledo, whence it flows west to Abrantes in Portugal. From Abrantes the river flows south-west, and passing Lisbon, enters the Atlantic about 10 miles lower down. At Peralejos, a few miles from its source, it is 1 foot deep, 15 paces broad, and confined between rocky walls 400 feet high. At the city of Toledo, it breaks through a romantic rocky pass, the walls of which are upwards of 200 feet high. From Villavelha, 18 miles within the Portuguese border, the T. is navigable to its mouth, a distance of 115 miles. Above Lisbon, the river widens like an estuary, being in some places 5 miles broad; opposite Lisbon, however, it is only one mile broad. The principal affluents are the Jarama, Guadarrama, Alberche, Alagon, and Zezere from the north, and the Guadiela and Rio del Monte from the south. Total length, 540 miles.

TAHI'TI or OTAHEITE, the chief of the Society Islands (q. v.), is 32 miles long, about 120 miles in circumference, and consists of two peninsulas, connected by an isthmus about 3 miles broad, but which is submerged at high water. Pop. 13,800, of whom more than 13,000 are natives. The chief town is Papiete. In 1880, T. was annexed by France, along with the other Society Islands. For the trade, &c. of T. see SOCIETY ISLANDS.

TAIL, ESTATE, is, in English Law, an estate given to A and the heirs of his body, or A and the heirs-male of his body, or some other class of heirs less extensive than the class of heirs-at-law. It was anciently a question whether in such a case A, the father, could defeat the right of the children, and break the entail. In England, it was early decided that A could, by a sham process, called a fine or Recovery (q. v.), break the entail; while in Scotland it was otherwise, at least since 1685, the Scotch legislature having legalized a mode of securing the entail, and preventing A, or any of his successors, from breaking it. See ENTAIL.

TAILOR-BIRD (*Orthotomus*), a genus of birds of the family *Sylviadæ* (q. v.), with a long graduated tail, the feathers of which are narrow. The species are numerous, natives of the East Indies and of the Indian Archipelago, and haunt cultivated grounds, where they are commonly seen in pairs. Their flight is rapid and undulating, and they seldom ascend above the lower branches of trees. The name *Tailor-bird* is derived from the way in which the nest is formed. Two leaves are taken at the extremity of a twig, and are sowed together by their edges, or a large leaf is sewed together; the necessary holes being made by the bill, and vegetable fibres forming the thread. Within the hollow thus

Tailor Bird and Nest (*Orthotomus longicaudus*).

made, a quantity of a cottony substance is placed to receive the eggs.

TAI'LZIE, the ancient term in the law of Scotland to denote a deed creating an entailed estate. See ENTAIL.

TAIN, a royal, parliamentary, and municipal burgh in the county of Ross and Cromarty, on the south shore of the Dornoch Firth, and 24 miles north-north-east of Inverness. There is no proper harbor. The most interesting building is a small ruined chapel, remarkably rude and simple in architecture, and said to date from the 13th c.; and there is also a collegiate church, founded in 1471, and an endowed academy incorporated by royal charter. Brewing and iron-founding are carried on. Pop. of royal burgh (1881) 2221.

TAINE, HIPPOLYTE ADOLPHE, a French critic, was born at Vouziers in Ardennes, 21st April 1828, and studied at Paris, where in 1853 he obtained the diploma of *docteur ès lettres*, for two essays, *De Personis Platonicis*, and *Essai sur les Fables de Lafontaine*. They were followed by his *Essai sur Tite Live* (1854), crowned by the French Academy; *Les Philosophes Français du dix-neuvième Siècle* (Paris, 1856); *Essais de Critique et d'Histoire* (Paris, 1857); *Histoire de la Littérature Anglaise* (Paris, 1864); *Philosophie de l'Art* (1865; Eng. transl.); *Notes sur l'Angleterre* (1871; Eng. transl.); and others.

In the *Littérature Anglaise* (Engl. transl., Edinburgh, 1872), the author surveys and criticises our whole literature from a point of view which is conceived to be rigorously scientific. According to T., there are three things to be borne in mind when writing the history of a nation's literature: first, the *race* to which the nation belongs; second, its *position* both geographical and in civilization in the different phases of its literary development; and third, the *period* or duration of these. Under this view, the history of literature assumes the character of a psychological problem. Among T.'s recent works is *Les Origines de la France Contemporaine*, of which the first instalment, *L'Ancien Régime*, appeared in 1875 (Eng. transl., 1876). In this the writer gives a graphic account of the social disease that led to the French Revolution. A picture of the revolutionary age itself followed in *La Révolution* (vol. ii. 1881). The New Régime is afterwards to be described. T. was elected a member of the Academy in 1878.

TAI-WAN-FOO, the capital of the island of Formosa (q. v.), on a large plain 3 miles from the south-west coast, with a pop. of 120,000. It is a large straggling town, contains many park-like spaces with fine trees and green lanes, and is surrounded by a high battlemented wall, six miles in extent. Its chief edifices are the residences of the mandarins, and the temples. The harbor of T., at Amping, is only a shallow open roadstead; trade is carried on only in five months of the year, cargo having to be carried in native boats. The chief export is sugar, which is grown all over the plain of Formosa; also rattan canes. About 27 miles to the south is the harbor of Takao, the headquarters of the customs staff; it is better than that of Amping. See a 'Description of Formosa' in the *Geographical Magazine* of 1877.

TAI-YUA'N, a city of China, in the province of Shan-si, on the Fuen-ho, an affluent of the Hoang-ho, 250 miles south-west of Pekin. It is said to be about ten miles in circumference, fortified and populous. Porcelain, iron wares, and carpets are manufactured.

TALAVE'RA DE LA REY'NA, a town of Spain, in New Castile, in the modern province of Toledo, is charmingly situated

on the Tagus, 75 miles south-west of Madrid. It is ancient, straggling, dirty, and inconvenient, is surrounded by interesting old walls, and abounds in antique picturesque fragments. It was formerly a flourishing town; but, of its manufactures, only that of silk is now carried on. Fruits are extensively produced in the vicinity. Here, on the 27th and 28th July 1809, Sir Arthur Wellesley, with 19,000 English and German troops, and about 34,000 Spaniards, who, however, with very trifling exceptions, were not engaged, defeated upwards of 50,000 veteran French troops, under Joseph Bonaparte and Marshals Jourdan and Victor. Pop. (1877) 10,029.

TALBOT, perhaps originally a name equivalent to Bloodhound (q. v.), but afterwards applied to a race of hounds, now extinct, or nearly so, which seem to have been kept for show rather than for use. The T. was of a pure white color, with large head, very broad muzzle, long pendulous ears, and rough hair on the belly. The White St. Hubert Dog was either the T. or a nearly allied breed. The T. is the badge of the ancient House of Shrewsbury (surname Talbot), and the crest of some of the princely Houses of Germany.

TALBOT, WILLIAM HENRY FOX, celebrated in connection with photography, was the son of William D. Talbot of Lacock Abbey, Wilts, and was born in 1800. He was educated at Harrow, and afterwards at Trinity College, Cambridge, where he took his degree with honors, and obtained the junior Chancellor's Medal in 1821. In the first parliament summoned after the passing of the Reform Bill, T. sat for Chippenham; but scientific investigation being more to his taste, he gave up politics, and devoted himself to the problem of fixing shadows, ignorant at the time of what had been effected in this department by Wedgwood and Davy. Step by step he discovered for himself a method of obtaining and fixing sun-pictures, and on the dissemination of a report as to Daguerre's successes in the same field, secured his just rights by publishing a paper (*Phil. Mag.* March 1839), in which the successive steps of his investigation and their result were detailed. See PHOTOGRAPHY. This process, by which a *Negative* (q. v.) was primarily obtained, was subsequently improved by his invention (patent dated February 8, 1841) of the Calotype (q. v.) process. Soon afterwards he obtained fresh patents, for an 'instantaneous process' (which seems to have well deserved the name, as by it a legible picture was obtained of a printed bill fastened to the rim of a wheel revolving 200 times per second), a mode of 'photographic engraving,' and a polyglyptic process. A later invention of his, patented in 1858, was called by him Photoglyphic Engraving; see the art. PHOTOGRAPHIC ENGRAVING. In 1842, T. obtained the medal of the Royal Society for his previous discoveries. Latterly he devoted himself to the study of general physics, and to philological and miscellaneous researches. He died 17th Sept. 1877. Amongst his works are *Hermes, or Classical and Antiquarian Researches; Legendary Tales; Illustrations of the Antiquity of the Book of Genesis;* and a work on *English Etymologies.*

TA'LBOTYPE, a photographic process, called by the inventor Mr. Fox Talbot, the Calotype Process (q. v.). Its essential features consist in the production in the camera of an image by light *on* the *surface* of chemically prepared paper, and this distinguishes it from other *paper* processes, and by consequence from other photographic processes.

TALC, a mineral allied to Mica (q. v.), and, like it, easily separated into very thin flakes, which are transparent and flexible, but not elastic, like those of mica. T. is composed almost entirely of silica and magnesia, in the proportions of 57—63 silica, and 30—35 magnesia, with 2—6 water. Its colors are silvery white, greenish white, and green. It has a pearly or semi-metallic lustre, and is unctuous to the touch, in which it differs from mica. It occurs crystallized, generally in hexagonal tables, or in long prisms: the primary form is a rhomboid. It is also found massive, in beds chiefly in micaceous schists, gneiss, and serpentine.—A kind called *Indurated T.*, or *T. Slate*, has a curved slaty structure, and is not separable into laminæ, like common talc. It approaches in character to steatite, and is used for similar purposes.

TALEGA'LLA, a genus of Gallinaceous birds, of the family *Megapodidæ*, having a strong, thick, and very short bill, the upper mandible curved and pointed; the head and neck almost quite naked; the wings short and round; the tail rather long, rounded on the sides; the legs strong, feathered a little below the joint of the tibia and tarsus; the tarsi covered with scales in front; the toes long and strong; the claws large and sharp. The species are natives of Australia and New Guinea. The best known is the BRUSH TURKEY (*T. Lathami*) of Australia, also known as the WATTLED T. and the NEW HOLLAND VULTURE, the latter name being given to it on account of its naked head and neck, covered in part with fleshy wattles. It is pretty common in New South Wales, inhabiting the most thickly wooded parts. It is a large bird, about the size of a turkey, with blackish-brown plumage. It is shy, and when pursued, endeavors to escape by running through the thickest *brush*, or by leaping to the lowest branches of a tree, from which it ascends higher and higher, branch by branch. It thus avoids the dingoes or native dogs, which, however, often hunt it down on open ground. It is easy game to the sportsman, who finds it roosting under shelter of the branches of trees during the heat of the day, and although several of the flock are shot, the rest keep their place undisturbed.

Brush Turkey (*Talegalla Lathami*).

The T. is generally seen in small flocks, and they make their nests together, the males heaping up, by means of their feet, mounds of several cart-loads of earth and decayed leaves, which are used from year to year, new materials being added every year. The eggs are hatched by the heat of the sun and of the fermenting mound, each egg being separately buried. The parent birds partially uncover them during the day. Nearly a bushel of eggs may sometimes be found in a single heap. The male bird pays great attention to the young after they are hatched, covering them up partially in the mound at night for warmth. The flesh of the T. is excellent, and the eggs are also very delicate and eagerly sought after. It is thought that this bird might easily be added to the list of our domestic poultry.

TALENT (Gr. *talanton*, from a root to balance or weigh), a word used by Homer to signify indifferently a balance, and a definite weight of some monetary currency. But the weight of money to which Homer applies the term talent was very different from that to which it was applied in later times. Tradition assigns to Pheidon, king of Argos, the introduction of the talent as a standard of money and weight.

The *exact* identity of the Æginetan talent with that known as the Babylonian, and generally employed in the East, points to its true origin. It was in all probability introduced into Greece by the Phœnicians, who also introduced a smaller monetary measure and weight, which was by the Greeks known as the Euboic talent. The names Æginetan and Euboic indicate that the talents to which these epithets apply were first used in Ægina and Eubœa; and though, in the East, the larger talent was used for silver, and the smaller for gold, after their introduction into Greece all such distinctive application was soon done away with. The use of the Euboic talent was mostly confined to Athens, Chalcis, and the Chalcidian colonies; while the Æginetan prevailed over the rest of the Greek world. In the 6th c. B.C., Solon introduced at Athens a new talent, which, as the *Attic talent*, succeeded, partly through its superior purity, and partly on account of the greater commercial activity of Athens, in supplanting the other two standards. These several talents were similarly subdivided into 60 minæ, the mina into 100 drachmæ, and the drachma into 6 oboli; and their relative proportions are, Æginetan T. : Euboic T. : Attic T. : : 30 : 25 : 18, both with respect to their values as weights, and as measures of monetary amount.

The following are the values as compared with English standards:

	AS WEIGHT. lbs. avoirdupois.		AS MONEY (SILVER). £.	s.	d.
Æginetan talent	= 95·	=	406	5	0
Euboic "	= 79·16	=	338	10	10
Attic "	= 57·	=	243	15	0

But by the same decree of Solon, a new commercial talent, of increased weight, was introduced, but only as a weight for goods, not for money.

TA'LIPAT PALM, or Great Fan Palm (*Corypha umbraculifera*), the noblest palm of the East Indies, a native of Ceylon, Malabar, &c. It grows to the height of 60, 70, or even 100 feet, and has a straight cylindrical trunk, crowned with a tuft of enormous palmate plaited leaves, which are divided near the outer margin into numerous segments, and are united to the trunk by spiny leaf-stalks. The leaves are usually about 18 feet long, exclusive of the leaf-stalk, and 14 feet broad; a single one being sufficient to protect 15 or 20 men from rain. At the age of 30 or 40 years, the tree flowers, and after ripening fruit, generally dies. It produces a long conical erect spadix, rising to the height of 30 feet from the midst of its crown of leaves, and dividing into simple alternate branches, the lower of which sometimes extend laterally 20 feet, the whole covered with whitish flowers, and forming a very beautiful and magnificient object. The fruit is very abundant, globose, and about an inch and a half in diameter. The leaves are used for covering houses, for making tents, and for many other purposes. On occasions of ceremony, every Singhalese noble is followed by an attendant, who carries above his head a richly ornamented T. P. leaf, which is capable of being folded up like a fan, and is then not thicker than a man's arm, and wonderfully light. The leaves of this palm are used in Malabar for writing upon, characters being traced upon them with an iron style. They are prepared for this purpose by boiling, drying, damping, rubbing, and pressing. The soft central part of the stem, pounded and made into bread, has often been of great use in times of scarcity.

Talipat Palm
(*Corypha umbraculifera*).

TA'LIPÉS, the scientific name for CLUB-FOOT (q. v.). It is derived from the Latin words *talus*, the heel, and *pes*, the foot.

TA'LISMAN (Arabic, but supposed to be derived from the Gr. *telesma*, in the sense of celebration of religious ceremonies), a species of charm, consisting of a figure engraved on metal or stone when two planets are in conjunction, or when a star is at its culminating point, and supposed to exert some protective influence over the wearer of it. The terms Talisman and Amulet (q. v.) are often considered nearly synonymous, but the proper distinctive peculiarity of the former is its astrological character. Talismanic virtues have often been attributed to a peculiarly marked or formed egg, and instances are recorded, by various authors, of eggs hatched with figures of comets or eclipses on them. A species of talisman, which has acquired considerable celebrity, is the Abraxas Stone (q. v.). A species of talisman, at present in use in Asia, is a piece of paper on which the names of the Seven Sleepers and their dog are inscribed. Pasted on the walls of houses, it is believed to be a protection against ghosts and demons.

TA'LLAGE (said by Lord Coke to be from Fr. *tailler*, to share or cut out a part), a name which has been sometimes applied generally to subsidies or taxes of every kind, but which, in its more proper and restricted sense, denotes those taxes to which, under the Anglo-Norman kings, the demesne lands of the crown and all royal towns were subject, which were far more rigorous and irregular than the taxes imposed on the gentry.

TALLAHA'SSEE, the capital of Florida, U. S., situated on a high plain, 180 m. E. of Pensacola, a well-planned, and so far well-built embryo city. It is celebrated for its salubrious, semi-tropical climate, and abundant springs of soft pure water. It is a station on the Jacksonville, Pensacola and Mobile Railway, at the junction of a branch to St. Marks, 23 miles distant on the coast. Pop. (1870) 2023.

TALLEYRAND-PERIGORD, CHARLES MAURICE DE, Prince of Benevento, the most subtle, shrewd, and unprincipled of all modern diplomatists, was born at Paris, February 13, 1754, of an ancient and distinguished family. His father, CHARLES DANIEL, COMTE DE TALLEYRAND-PERIGORD (b. 1734, d. 1788), was an officer in the French army, and fought all through the Seven Years' War.

CHARLES MAURICE being the eldest son, would in all probability have been designed for a military career, had not an accident, which he met with when only a year old, rendered him lame for the rest of his life. He was, in consequence, trained for the church, and studied at St. Sulpice, the Sorbonne, and Rheims, but at no period did he betray the least inclination towards a Christian, or even a moral life. At the age of 20, he came to Paris, and rapidly acquired a reputation for licentiousness. This, however, did not prevent him from obtaining several ecclesiastical benefices, among others, the Abbacy of St. Denis, in the diocese of Rheims (1775). Appointed *agent-général* for the clergy in 1780, a lucrative and important post, which brought him into close connection with the heads of the administrative in France, he now began a serious apprenticeship to public business, without, however, pausing in his career of gallantry. So notorious was his *infâme conduite* (as Mirabeau calls it), that, for some years, Louis XVI. shrank from conferring on him further ecclesiastical preferment, and it was only on account of his administrative abilities, that, in 1788, he obtained the bishopric of Autun..

When the convocation of the *Etats-généraux* took place, in the year following, he was elected by the clergy of his diocese to represent it, and pronounced in favor of an amalgamation with the *Tiers Etat*, which, on the 17th June, had constituted itself the *Assemblée Nationale*. His attitude and speeches recommended him to the notice of the popular party, and along with Mounier, Sieyès, and Lally-Tolendal, he was appointed to draw up a constitution for the nation. In this capacity, he took an active part in framing the famous Declaration of Rights, and he was one of those selected (after the destruction of the Bastile) to investigate the causes and peculiar features of the revolutionary movement. It was T. who proposed (October 10, 1789) the startling measure for the confiscation of church property, arguing that such property did not really belong to the church, but to the nation, and that if the rights of the existing clergy were secured, the nation, or its representatives, were at liberty to apply it to any purpose they saw fit. On February 13, 1790, a decree for the suppression of religious orders was carried, in spite of a vehement opposition, and three days after, T. became President of the Assembly. He was one of the first among his order to take the oath to obey the constitution (December 28, 1790), and eagerly urged the clergy of his diocese to follow his example. About the same time, he demitted his bishopric of Autun, yet, in the following February, we read of his consecrating two new bishops (those of Aisne and Finisterre), and although denounced in pontifical briefs as a schismatic, declaring his sincere attachment to the Holy See!

Our space does not permit us to describe the important share that T. had in the financial deliberations of this first period of the Revolution, but we must specially note the sagacity he displayed in pointing out the perils attending the issue of assignats, his skill in preparing the way for the adoption of the principle of uniformity in weights and measures, and of an arc of a meridian as the basis of the new metrical system; and above all the luminous intelligence shown in the Report which he gave in to the Assembly (September 10 and 11, 1791) upon Public Instruction—a Report conceived in the liberal and comprehensive spirit of the times, and which was undoubtedly the model followed in all the great changes that subsequently took place, when France reorganized her educational system.

In 1792, when the old European despotisms were obviously preparing to coerce the young republic, T. was sent to London—but not in an official character—to negotiate with the English government. He did not make a favorable impression on George III. or on Pitt. Thrice, in that year, he essayed to procure a recognition of the republican government, but in vain. The 'September massacres' (see SEPTEMBRISTS) made even the stanchest admirers of the Revolution shudder. Nothing, therefore, could be done; and T. would doubtless have returned to France, had not a letter of M. de Laporte, *intendant* of the civil list of Louis XVI., been discovered, in which T. was noted as a man 'disposed to serve' the king. He was immediately placed on the list of *émigrés*, i. e., proscribed (December 1792); and thus his connection with the Revolution—fortunately, we believe, for his reputation—was suddenly brought to a close. His career as an exile was (as is generally the case) one of hardship and insignificance. He remained in England till forced to leave by the 'Alien Bill,' when he sailed for the United States (February 1794), where he lived for more than a year.

After the fall of the Terrorists, he procured the revocation of his banishment; and in March 1796, re-entered Paris, having paved the way for a favorable reception by a series of the most adroit and judicious intrigues. We may first note, *en passant*, that in private life he continued to play the *rôle* of a gay Lothario.

T. attached himself to the *cercle constitutionnel* that gathered round Madame de Staël, and so dexterously did he comport himself, that, in 1797, he was named Minister of Foreign Affairs in place of C. Delacroix. The rise of Bonaparte was a phenomenon which so penetrating a politician as T. could not overlook. He cultivated the friendship of the young general with a sagacious assiduity, keeping him constantly *au courant*, when away from Paris, of the situation of parties, and became his confidant in those designs, the execution of which resulted in the overthrow of

the Directory, Brumaire 18 (q. v.), 1799. After this *coup d'état*, the subtle finesse of T. was constantly in requisition. He divined, with a sort of miraculous cleverness, the ideas of Bonaparte, and his whole policy was directed to consolidate the power and authority of his master. In all the diplomatic negotiations that followed the victories of France under the Consulate, he had the principal part; but Bonaparte thoroughly understood his man, and T. was quite conscious, as M. Thiers remarks, that he could never impose on his superior. It was he who proposed the kidnapping of the Duke d'Enghien (q. v.); and it was by his instructions that the crime was consummated, in spite of the vehement opposition of Josephine, whose honest indignation led her to denounce him, as a *maudit boiteux* (cursed cripple).

T. took an active part in preparing the way for the establishment of the Empire (1804); and when, in the following year, England, dreading a French invasion, formed a powerful European coalition against France, it was by the ingenuity of T. that it was partially broken up. To him, as much as Napoleon, was owing the organization (1806) of the famous *Confederation of the Rhine* (q. v.), which so effectually served the ambitious designs of the emperor. In conducting the negotiations that brought about this Confederation, he exhibited a truly Macchiavellian art. Napoleon was not ungrateful. T. received the principality of Benevento, which he held as an imperial fief.

When the views of the emperor in regard to Spain became apparent, T., who for more than a year had rather fallen into disfavor with Napoleon, came forward with a plan of his own, which, however, was not adopted; but his presence at the interview between Alexander and Napoleon at Erfurt (1808), proved that his influence was as yet undiminished. The ill success of the Spanish war (at first) induced T. to pronounce against it, and occasioned violent invectives on the side of his sovereign, to which the accomplished cynic (who retained to the last the manners of the old noblesse) only replied by the sarcasm: '*Quel dommage qu'un si grand homme soit si mal élevé!*' (what a misfortune that so great a man should have been so badly educated!).

T. declared in favor of the Austrian marriage; but already the *entente cordiale* between him and Napoleon was ruptured, and he began to look forward to a future in which his own schemes might be hostile to those of the emperor. In a word, he was meditating treachery against the power by which he had risen. The victories of Wellington in Spain, and the reverses of Napoleon in Russia and Germany, widened the breach between them, and T. now only waited the decisive moment in which to ruin the cause of his master. He became the center of a group of Parisian malcontents, whose influence grew with the advance of the allied armies, and finally, communications were opened up with the latter and with the Bourbons. It was T. who dictated to the senate the terms of the deposition of Napoleon; and on the restoration of the Bourbons, he became Minister of Foreign Affairs in the first government of Louis XVIII. He was also head of the French legation in the celebrated Congress of Vienna; but after the battle of Waterloo, a coolness sprung up between him and the Bourbons, and he was relieved of all his offices. Henceforth, his career is uninteresting to the student of history. He caballed to regain power, but in vain; and during the reigns of Louis XVIII. and Charles X., he was merely a discontented senator, who never lost an opportunity of injuring the court and the government.

After the July Revolution, Louis Philippe employed him as ambassador at the English court, where he contrived to bring about a friendly feeling between the new monarchy and the English government. During the brief remainder of his life, nothing externally notable occurred. He died at Paris, 17th May 1838. T. was neither a wise, nor a great, nor a good man; but he was infinitely cunning, dexterous, and supple. He had a larger share than most men of what Carlyle calls 'vulpine understanding;' and if this world had had nothing but knaves and fools in it, the policy and principles of T. might have enjoyed a perpetual triumph; but there were forces in the world, both intellectual and moral, of which he took no account, but which took account of him, and with all his amazing cleverness, dropped him into obscurity and disgrace. T. was an 18th c. sceptic, over whom the Revolution had exercised little influence, while France, and indeed all Europe, had been roused into earnestness by the outburst; and when the ideas of political liberty began their swift, irresistible march, this *diable boiteux* inevitably lagged behind, and sunk out of sight. T. has left *Mémoires*, which are not to be published till 1890. For estimates of his character and policy, see the *Mémoires Politiques* of Lamartine; the *Histoire de Dix Ans* of Louis Blanc, where T. is rigorously criticised; the *Mémoires* of Guizot; works by Mignet and Bastide; and the *Correspondance inédité du Prince T. et du Roi Louis XVIII.* (2 vols., 1881; Eng. transl. 1881), edited by Pallain.

TALLICOO'NAH OIL. See CARAPA.

TALLIEN, JEAN LAMBERT, a French Revolutionist, was born at Paris in 1769, and first became notable in the beginning of 1792 as the editor of a Jacobin journal, called *L'Ami des Citoyens*, meant to be a friendly rival of Marat's *Ami du Peuple*. From this date, his influence over the lower orders of the city steadily increased. He was conspicuous in the events of the 10th August, and in consequence received the appointment of secretary to the *Commune Insurrectionelle*. He promoted, and afterwards defended the massacres of September; and on account of his unscrupulous zeal, was elected to the Convention by the department of Seine-et-Oise. There he became the apologist, if not the advocate of Marat, denounced the minister Roland, urged with savage emphasis the condemnation of Louis XVI., and was rabidly eager for the ostracism and and annihilation of the Girondists (q. v.). Towards the close of 1793, he was sent to Bordeaux, charged with the mission of destroying every trace of the party he hated. His career in the south-west was a mixture of reckless cruelty and shameful vice. To the odious tyrannies of a proconsul, he added the luxurious profligacy of a satrap. Fortunately for his countrymen, a passion which he conceived for one of his victims, Madame de Fontenay (*née* Cabarrus), led him to pause in his bloody course. He was called to Paris to account for this singular change in his disposition, satisfied his associates (by paroxysms of patriotic vehemence) that it meant nothing particular, and on the 22d March 1794, was chosen president of the Convention. Robespierre, however, had found out the sort of man that T. was. He hated him for his insincerity and immorality, felt instinctively that he could not be trusted, denounced him severely in the Convention, and on the 14th of June got his name erased from the list of members at the Jacobins.

T. recognized his danger, and taking advantage of the reaction against the Terrorists (though himself one of the basest of the set), already beginning to show itself in France, he dexterously rallied the Dantonists, Hebertists, and others against the rigorous government of Robespierre, St. Just, and Couthon, and brought about the events of the 9th Thermidor (27th July 1794), which caused the fall of [the triumvirate. T. now became for a short time one of the most notable and influential men in France; lent his aid to suppress the Revolutionary Tribunal and the Jacobin Club, and drew up the accusations against Carrier, Le Bon, and others of the Terrorists! But France could not long tolerate this affectation of virtue on the part of one so infamous; his past life was perpetually held up to scorn and reproach; and finally, on the 20th of May 1798, he was forced to leave the Council of Five Hundred. Henceforth, his career is pitiably insignificant. He accompanied Bonaparte to Egypt as *savant* (!), quarreled with General Menou; and on his return to France, was captured by an English cruiser, and brought to England, where the Whig Opposition was stupid enough to make a hero of him (1801). Soon after, he returned to France, and was contemptuously dismissed as consul to Alicante by Talleyrand, outlived (in utter obscurity) the Empire of Napoleon, and died at Paris, 16th November 1820, supported in his last days by the heirs of the monarch for whose death he had inhumanly clamored.

TALLOW. See OILS AND FATS.

TALLOW, MINERAL. See MINERAL TALLOW.

TALLOW TREE, the name given in different parts of the world to trees of different kinds which produce a thick oil or vegetable tallow, or a somewhat resinous substance, which, like tallow, is capable of being used for making candles. The T. T. of Malabar (*Vateria Indica*) is a very large tree of the natural order *Dipterocarpaceæ*. It has leathery leaves, of 4—10 feet long, and panicles of white, fragrant flowers, with five petals. The stem is often 16 feet in circumference. By incisions in the stem, East India copal is got; and by boiling its seeds, there is obtained a firm, white, vegetable tallow, which, as it has no unpleasant smell, is particularly suitable for making both candles and soap. —The T. T. of China (*Stillingia sebifera*) belongs to the natural order *Euphorbiaceæ*. The capsules are internally divided into three cells, each containing a nearly hemispherical seed, which is covered with a beautifully white vegetable tallow. This the Chinese collect for the manufacture of candles, in order to which, the capsules and seeds are crushed and boiled, and the fat skimmed off whilst in a melted state. To give it a firmer consistency, wax is added to it, in the proportion of three parts to ten of the vegetable tallow. Linseed oil is also added. The candles made of it are beautifully white. This tree has been introduced into North America, is cultivated about Charlestown and Savannah, and is almost naturalized in the maritime parts of Carolina. It presents a very beautiful and remarkable appearance at the approach of winter, when the leaves become bright red, and the pericarps falling off, leave the white seeds suspended by threads.—The name T. T. is sometimes given in North America to a species of CANDLEBERRY (q. v.).—The T. T., or BUTTER AND TALLOW TREE of Sierra Leone, is *Pentadesma butyracea*, of the natural order *Guttiferæ*, the fruit of which furnishes a solid oil.

TALLY (Fr. *tailler*, to cut), the name given to the notched sticks which, till a recent period, were used in England for keep-

ing accounts in Exchequer, answering the double purpose of receipts and public records. They were well seasoned rods of hazel or willow, inscribed on one side with notches indicating the sum for which the tally was an acknowledgment, and on two opposite sides with the same sum in Roman characters, along with the name of the payer and the date of the transaction. Different kinds of notches, differing in breadth, stood for a penny, a shilling, a pound, £20, £100, and £1000. The tally was cleft through the middle by the deputy-chamberlain with knife and mallet, so that each piece contained one of the written sides, and a half of every notch; and the one half was retained by the payer as his receipt, while the other was preserved in Exchequer. At the union of England and Scotland, a store of hazel rods for tallies was sent to Edinburgh, but never made use of. Act 23 George III. c. 82 abolished the use of tallies in Exchequer, and the old tallies were ordered to be destroyed by 4 and 5 Will. IV. c. 15. The destruction of the Houses of Parliament by fire in 1834 is supposed to have arisen from the overheating of the flues in which the discarded tallies were being burned.

TALLY SYSTEM is the name given to a mode of buying goods much in vogue among the wives of poor men, whereby they get goods, chiefly articles of dress and cheap finery, on credit, or on terms of payment by small weekly sums till the debt is paid. It, in point of law, gives rise to the following hardships or disadvantages whenever, as is usually the case, the wife, in the absence of, and without the knowledge of, the husband, enters into the contract, and purchases goods which are beyond her station. The husband, when sued in such a case on the contract, can set up a good defence. If he had given his wife sufficient clothes, either in specie or the means of buying them, he is not liable to pay any tradesman who, without his sanction, supplies the wife with more, especially if these are articles of finery. It is only in the case of the articles being strictly called necessaries, that he will be bound at all; and as regards women of the lower classes, a court or jury would construe the word 'necessaries' very strictly in favor of the husband. If the articles are extravagant, and beyond the station of the wife, the husband is then not liable to pay for the price, and no court will compel him to do so.

The only ground on which he can be made liable will be, that the husband knew of the purchase, and directly or indirectly sanctioned it; as, for example, by seeing her wear the clothes, and not returning them, or giving immediate notice to the tallyman that he objected to the purchase. Nevertheless, it must be confessed that judges are not uniform in their decisions, and some too easily give effect to the contract, for want of strong evidence on the part of the husband of the earliest disavowal of it he could make. The tallyman generally makes it a stipulation that the bargain shall be kept secret for a certain length of time. Nevertheless, if, when it is discovered, the husband at once repudiates and returns the articles, it is the tallyman's own fault if he is then obliged to take them back after they have been partly used, and he cannot fix the husband with liability.

TALMA, FRANÇOIS JOSEPH, an eminent French tragedian, was the son of a dentist, and was born at Paris, 15th January 1763. He made his *début* as an actor in 1787, at the Comédie Française, where he played the part of Séide in *Mahomet*. He achieved considerable success, but apparently not enough to excite any very high anticipations of his future career, and for upwards of a year he figured only in secondary characters. The first thing that induced the public to notice him attentively was an innovation in the matter of costume when playing the part of Proculus in the tragedy of *Brutus*. Previously, actors had worn the garb of their own country, and even their own time; and Roman senators stalked about the stage dressed as Parisian 'swells' of the 18th century.

The absurdity of this fashion forcibly struck T., who set himself to amend it, and in the part referred to appeared in the green-room clothed in a Roman toga, greatly to the astonishment of the company, one of whom (Louise Contat) exclaimed: 'Good God! look at Talma; how ridiculous he is! *Why, he has quite the air of an ancient statue!*' The compliment was as exquisite and as just as it was unintentional. Henceforth, a rigorous accuracy in costume became a point with T.; but his first grand triumph in acting was won, 4th November 1789, when he played Charles IX. in Chenier's piece of that name. During the Revolution, he was in the zenith of his popularity, and made peculiarly his own such characters as Abdelazis, in *Abdelazis et Zuléma;* Othello; Néron, in *Epicharis et Néron;* Pharan, in *Abufar;* and Egisthe, in *Agamemnon*. Exceedingly arrogant and choleric, he was often at strife, either with the public or with some of his fellow-actors. T. was a favorite with Napoleon and Louis XVIII. Some of his later characters were among his best, as Marigny, in *Les Templiers;* Leicester, in *Marie Stuart;* Sylla; Oreste in the *Clytemnestre* of Soumet; Leonidas; and Charles VI. He died 19th October 1826.

TA'LMUD (from Heb. *lamad*, to learn)—i. e., Study, by way of eminence—is the name of the fundamental code of the Jewish civil and canonical law, comprising the Mishna (q. v.) and the Gemara (q. v.), the former as the text, the latter as the commentary and complement. We have spoken under HALACHA and HAGGADA of the gradual development of this 'Oral,' or, chronologically speaking, Post-mosaic Code. We have also there mentioned the older collections upon which the Mishna was framed, and finally redacted in the form in which we now possess it. The oldest codification of Halachoth, or single ordinances, is due to the school of Hillel (q. v.). Simon ben Gamaliel the Patriarch (166 A.D.) and his school carefully sifted the material thus brought together; and in the following generation, through Jehudah Hanassi (219 A.D.) and his disciples, the work was brought to its close in six portions (Sedarim), 63 treatises (Mesichtoth), and 524 chapters (Perakim), which contain the single Mishnas. A summary of its contents is given under MISHNA. But besides this authoritatively compiled code, there were a number of other law collections, partly anterior to it, and not fully embodied in it, partly arising out of it—as supplements, complements, by-laws, and the like—partly portions of the ancient Midrash (q. v.); partly either private text-books composed by the masters of the academies for their lectures or enlargements of the existing Mishna. All this additional legal material was collected, not rarely together with the dissensions which begot it, under the name of *Boraitoth*, by Chia and his school, in the succeeding generation.

Not to be confounded with them, however, are the collections of *Toseftas* or *Great Mishnas*, which, commenced at the time of Jehudah Hanassi himself, and continued after his death by Chija and Hoshaja, embody much of what has been purposely left out in the concise Mishna; that only embraced the final dicta and decisions. Such 'additions' we possess now to 52 treatises, forming together 383 Perakim, or chapters. All these different sources of the 'Oral Law'—finally redacted before the end of the 3d c., though probably not committed to writing until 550 A.D.—belong to the period of from about 30 B C. to about 250 A.D. This great mass of legal matter, although apparently calculated to provide for every case, if not for all times, was yet found insufficient. The dicta of later masters, the decisions of the courts, the discussions on the meaning and purport of special traditions, the attempts at reconciling apparent contradictions in the received material, the amplifications or modifications of certain injunctions rendered necessary by the shifting wants and conditions of the commonwealth—all these and a number of other circumstances made a further codification peremptory.

We must not omit to state here that this Mishna (Mathnisin), although it contained nothing but what were indigenous laws and institutions, was yet not a little influenced—if the very fact of its redaction was not indeed caused—by the spirit of the times. At Berytus, at Alexandria, at Rome, the legal schools were then in their most vigorous stage of development, and everywhere system and method were being introduced into what till then had been a vast complex of traditional and popular institutions, decrees, and decisions. The Mishna, in all respects, fulfilled the conditions reasonably to be demanded from such a text-book as it was intended to form; it was clear, concise, complete, and systematic, and, moreover, composed in as classical a Hebrew as still could be written in those days of decadence of the 'sacred language.'

The further development of this Supplementary, Oral, or Second Law, in fact, rather an exegesis thereof, together with the discussions raised by apparent contradictions found in the individual enactments of the Mishnic doctors, is called Gemara Discussion, Complement, or, according to another explanation, Doctrine. Whatever the original meaning of the root (*gamar*), it certainly allows of all these significations. This Gamara contains, apart from the Halacha (q. v.), which is generally written in Aramaic, also a vast number of non-legal, chiefly Hebrew, fragments—homiletic matter, tales, gnomes, legends, and the like—called Haggada (q. v.).

There are two Talmuds, the one called the Talmud of the Occidentals, or the 'Jerusalem' (Palestine) Talmud, which was closed at Tiberias, and the other, the 'Babylonian' Talmud. The first of these now extends over 39 treatises of the Mishna only, although it once existed to the whole of the first five *Sedarim* or portions. Its final redaction—falsely attributed to R. Jahanan (died 279)—probably belongs to the end of the 4th c. A.D.; but the individual academies and masters through whom it received its completion cannot now be fixed with any degree of certainty. There is less discussion and more precision of expression in this than in the second or Babylonian Talmud, emphatically styled 'our Talmud,' which was not completed until the end of the 5th c., and which makes use of the former. As the real editor of the Babylonian Talmud, is to be considered Rabbi Ashe, president of the academy of Syra in Babylon (365—427 A.D). Both the Mishna and the Palestine Gemara had, notwithstanding the brief period that had elapsed since their redaction, suffered greatly, partly by corruptions that had crept into their (unwritten) text through

faulty traditions, partly through the new decisions arrived at independently in the different younger schools—of which there flourished many in different parts of the Dispersion—and which were at times contradictory to those arrived at under different circumstances in former academies.

To put an end to these disputes, and the general confusion arising out of them, which threatened to end in sheer chaos, R. Ashe, aided by his disciple and friend Abina, or Rabina (abbr. from Rab Abina), commenced the cyclopean task of collecting anew the enormous mass of Halachistic material which by that time had grown up. The method he pursued was simple enough. His disciples met twice a year at Syra, in spring and in autumn. At the spring gathering, he gave out all the paragraphs of one treatise; and the disciples had the task to find out until the autumn meeting what opinions the different schools had pronounced on the special points thereof. He then investigated the whole critically, and put it into shape according to a certain order. This process took him, with the assistance of ten secretaries, no less than thirty years; and another thirty years were spent by him in the revision of the work, with which he proceeded in the same manner as he had done with the compilation itself. The final close of the work, however, is not due, as generally stated, to R. Jose, his successor at the academy (died 475), but to the school of the Saburaim at the end of the 5th century.

The Babylonian Talmud, as now extant, comprises the Gemara to almost the whole of the 2d, 3d, and 4th *Sedarim* (portions), further to the first treatise of the first, and to the first of the last order. The rest, if it ever existed, seems now lost. The whole work is about four times as large as the Jerusalem one, and its 36 treatises, with the commentaries generally added to them in our editions (Rashi and Tosafoth), fill 2947 folio leaves. The language of the Talmud is, as we said, Aramaic (Western and Eastern), or 'Chaldee,' closely approaching to Syriac. The minor idiomatic differences between the two, are easily accounted for by the different time and place; but the additional matter—quotations and fragments from older Midrash and Gemara collections, Haggada, &c.—is, as before stated, principally written in Hebrew.

The masters of the Mishna (Tanaim) and of the Gemara (Amoraim) were followed by the Saburaim (see above). The code of the Oral Law had come to a close with the second named; and not its development, but rather its proper study, elucidation, and carrying into practice, was the task of the generations of the learned that followed. Apart from this, the Aramaic language itself began to die out as the popular language, and required a further study. The Saburaim no longer dared to contradict, but only opined on the meaning and practicability of certain enactments, and undertook the task of inculcating and popularizing the teachings laid down by their sires: apart from bestowing proper care upon the purity of the text itself, and adding some indispensable glosses. Their activity was at its height in the 8th c., when Karaism (see JEWISH SECTS), which utterly denied the authority of the Talmud, sprang into existence.

Respecting, however, this authority of the Talmud itself, there has never been anything approaching to a canonicity of the code, or of a reception of it as a binding law-book by the whole nation. The great consideration in which it was always held is owing partly to its intrinsic value, and to the fact of its becoming the basis of all further development of Jewish literature (it being undeniably the most trustworthy receptacle of the traditional Jewish law), and partly to a prosecution against the Jews in the Persian Empire at the time of Jesdegerd II., Firuz, and Kobad, who closed the schools and academies for a space of nearly 80 years, during which this book was the sole authoritative guide of public conscience, and remained endowed with its importance even when the schools were restored. The best commentaries of the Mishna are by Maimonides and Bartenora; of the Babylonian Talmud by Rashi (q. v.) and the *Tosafists* of France and Germany. An abstract of the Talmud for practical (legal) purposes by Maimonides (q. v.) is called Mishne Thorah.

The Mishna was first printed at Naples, 1492; the Talmud of Jerusalem at Venice about 1523. The Babylonian Talmud was first published at Venice in 1520. It is generally printed in twelve folios, the text on the single pages being kept uniform with the previous editions, to facilitate the references. No translation of the Gemara has ever been carried further than a few single treatises. The complete Mishna, on the other hand, has been translated repeatedly into Latin, German, Spanish, &c., by Surenhus, Rabe, Jost, and others. We must refrain, in this place, from attempting a general characterization of the Talmud, a work completely *sui generis*. It will assuredly some day, when properly investigated, prove one of the most important records of humanity. Nothing can give even an approximate idea of the immensity of material, historical, geographical, philological, poetical, that lies hidden in its mounds. A contribution to the records of fanaticism may also be found in the 'exoteric' history of the Talmud, which was, albeit utterly unknown save by a few garbled extracts, prohibited, confiscated, burned, and generally prosecuted and inveighed against by emperors, popes, theologians, and fanatics generally, from Justinian down almost to our own day, as perhaps no other book has ever been.

In our own times, however, its value begins to be recognized by great scholars, not merely as the only source of the knowledge of Judaism, but as the chief source—next to the gospels—even for the history of the origin and early days of Christianity; a notion long ago hinted at by eminent divines like Lightfoot and others. See also JEWS, MIDRASH, MISHNA, HALACHA, HAGGADA; and an important essay in the *Literary Remains* of Em. Deutsch, author of the above article.

TA'LPIDÆ. See MOLE.

TALUS, a term employed in Geology, to designate the sloping heap which accumulates at the base of a rock or precipice, from fragments broken off by the weather, or materials in any way carried over it. The term is also applied to the slope of a wall which diminishes in thickness as it rises.

TAMA'RA SPICE, a favorite mixture of condiments used by the Italians. It consists of powdered cinnamon, cloves, and coriander seeds in equal parts, and half the same quantity of aniseed and fennel-seed powdered.

TA'MARIN (*Midas*), a genus of South American monkeys, small and beautiful, with short muzzle, prominent forehead, long nails, which, except on the hinder thumbs, are formed like claws, the tail longer than the body, not prehensile, and covered with hair so as to resemble the tail of a squirrel. The SILKY T., or MARAKINA (*M. rosalia*), is the best known of the genus. It is of a golden yellow color, with fine silky hair, of which it is exceedingly careful, to keep it free from stain. It is often brought to Europe, but is very tender, and seldom lives long. It is a very gentle and playful creature. The hair of the head and neck is elongated, so as to form a wig or mane; but this character appears far more strongly in the LITTLE LION MONKEY (*M. leonina*),

Little Lion Monkey (*Midas leonina*).

which inhabits the eastern slope of the Cordilleras, and of which, although it is a very small animal not many inches long, the appearance is an amusing caricature of that of the lion.

TA'MARIND (*Tamarindus Indica*), a beautiful tree, of the natural order *Leguminosæ*, suborder *Cæsalpineæ*, a native of the East Indies, but now very generally cultivated in warm climates. Only one species is known (*T. Indica*), a spreading tree, 30 or 40 feet high, with alternate pinnate leaves, which have from 12 to 15 pair of small leaflets, and fragrant flowers, with three petals, the pods brown and many-seeded, as thick as a man's finger, and about six inches long. The pods are filled with a pleasant, acidulous, sweet, reddish-black pulp. It is brought to Europe, mixed with seeds and fibres, in the form of a mass resembling jam, from the East and West Indies, and the Levant. Tamarinds are generally preserved by throwing hot syrup on the ripe pulp; but a better method is to put alternate layers of tamarinds and sugar in a stone jar, the color and taste being thus more like those of the fresh pulp. The wood of the T. tree, and especially of its roots, is a cabinet wood of much beauty, but of extreme hardness, so that it is wrought with difficulty.—The pods of some other trees of genera allied to *Tamarindus* are filled with a similar pulp, which is used in the same way, as the T. Plum of India (*Dialium Indicum*), and the Brown and Velvet Tamarinds of Sierra Leone, species of *Codarium*.

On chemical analysis, tamarind pulp is found to contain citric, tartaric, and malic acids; potash, sugar, vegetable jelly, &c. As a salt of copper is a common adulteration, a piece of polished iron (a knife, for example) should be plunged into the pulp, and left in it for an hour, when, if copper be present, it will be deposited on the iron. Tamarind pulp is refrigerant and gently laxative; and in combination with more active remedies, is often employed in the diseases of children. It is used in India as a cooling article of food, and a kind of sherbet is also formed from it; it is also an excellent addition to curries. Tamarind tea is made by infus-

ing tamarinds in boiling water; when cold, it forms an agreeable and cooling drink in inflammatory or febrile disorders. Tamarind whey is prepared by boiling one ounce of tamarinds with a pint of new milk, and straining: this also is an excellent cooling drink in similar cases.

TA'MARISK (*Tamarix*), a genus of plants of the natural order *Tamaricaceæ*. This order contains rather more than forty known species, all natives of the warmer parts of Europe and Asia, and of Africa, generally growing in arid situations. Some of them are herbaceous, others are shrubs or small trees, with rod-like branches, scale-like leaves, and small flowers in close spikes or racemes. The calyx has four or five segments; the corolla four or five petals; the stamens are hypogynous, equal in number to the petals, or twice as many; the pistil has three styles; the fruit is a one-celled capsule, with numerous hairy seeds. The COMMON T. (*T. Gallica*) grows in sandy places in the countries near the Mediterranean, and has been naturalized in some places on the southern coasts of England. It sometimes attains a height of 30 feet. The twigs seem to possess tonic properties, and their medicinal virtues were once in high repute. The ashes of this and some other species of the genus contain much sulphate of soda.

Common Tamarisk (*Tamarix Gallica*).

The ORIENTAL T. (*T. orientalis* is one of the few trees to be seen in the Arabian and African deserts, with the sands of which it seems to struggle more than any other tree or shrub. Its leafless appearance accords with the surrounding desolation. It is called *atlé* or *ethel*, and its wood is used both for fuel and for many economical purposes.—Galls are found on some species in India; and are valued both for medicinal use and for dyeing. *T. mannifera*, perhaps a variety of *T. Gallica*, yields the kind of Manna (q. v.) known as Mount Sinai manna.—The GERMAN T. *Myricaria Germanica*) belongs to another genus of this order. It is a smaller shrub than the Common T. and abounds in many parts of Europe and Asia, although not found in Britain. It was formerly supposed to possess valuable medicinal properties, but is now little regarded.

TA'MBOUR (Fr. *tambour*, drum), a frame upon which muslin or other material is stretched for embroidering. The tambour frame originally was made round. Tambour-work was extensively employed for the decoration of large surfaces of muslin, &c., for curtains and similar purposes; but pattern-weaving has been brought to resemble it so closely, that it is being rapidly superseded.

TAMBOUR, in Fortification, is a small work, usually a timber stockade, about 6 feet high, and loopholed. Its object is to defend a gateway, the road into a village, or to afford flanking fire on a bridge, &c. The tambour on the covered-way is the traverse which closes an entrance from the glacis.

TAMBOURI'NE, a very ancient musical instrument of the drum species, much used by the Biscayan and Italian peasants at their festivities, and sometimes introduced into orchestral music where the subject of the piece is connected with a people who use it, as the Basques, gipsies, or peasants of the Abruzzi. It is composed of a piece of parchment, stretched on the top of a hoop furnished with little bells, and is sounded by the hand, fingers, or elbow. When sharply struck by the hand, the tambourine has not much effect, unless used in numbers. When sounded by gliding the fingers along the parchment, a roll results, in which the bells are chiefly heard; and by rubbing the parchment, without quitting it, with the whole weight of the thumb, the instrument gives out a wild, grotesque sound, which is sometimes of service in masquerade scenes.

TAMBO'V, a government in the south-east of Great Russia, bounded on the E. by the governments of Penza and Saratov. Area, 25,542 sq. m.; pop. (1880) 2,405,713. The southern districts are hilly; the interior is a somewhat elevated plateau, with a gradual slope toward the north. Several lakes are found in the north of the government, and the principal streams are the Tsna, an affluent of the Moksha, and the Moksha, which is itself an affluent of the Oka. The climate of T., owing to its exposure to the biting north winds, against which there is no protection, is more severe than in neighboring governments. The soil in the central and southern districts is a rich vegetable mould, and is very productive. In the north, clay predominates, and requires much manure. The chief agricultural products are rye, wheat, buckwheat, oats, hemp, and flax. The larger forests are found in the north, and pasture-lands extend for the most part along the banks of the rivers. Agriculture and cattle-breeding are the principal employments; and some of the breeds of oxen, sheep, and horses are excellent. Cloth, distilled liquors, tallow, and iron are the chief manufactures. The products of the government are exported largely by the Tsna and the Moksha to the Oka and Volga.

TAMBOV, capital of the government of the same name, on the Tsna, 750 miles south-east of St. Petersburg. It was founded in 1636 under the Czar Michael Theodorovitch, and served as a fortress against Tartar invasion. It is regularly built, and, though the houses are mostly of wood, there are several important institutions, as the college, the military hospital, &c. T. is the seat of considerable manufacturing trade, there being in all 28 factories, in which cloth and sailcloth are extensively made. The chief articles of trade are leather, wool, tallow, and salt beef. Pop. (1880) 26,403.

TAME ANIMALS, in point of law, render their owners subject to certain liabilities. There is no restriction as to what wild animals may be tamed; and the person who tames one, and retains possession, becomes the owner of it. There is, however, in all such cases an obligation on the owner to keep the animal with due care; and if it tends to be a nuisance to a neighborhood, he would, in extreme cases, be liable to an indictment, or in most cases, to an action of damages. If the animal tamed is naturally ferocious, then it is incumbent on the owner to keep it secure, so as not to allow it an opportunity of doing mischief; and in case of accidental escape, it is seldom that a jury will be pursuaded that the owner is not guilty of negligence, and liable for the damage done. There is a certain class of animals which may exist in a wild state, yet by long use, or a second nature, have become domesticated, such as dogs and cats, and are called *mansuetæ naturæ*, in contradistinction to ferocious animals, such as lions.

With regard to animals *mansuetæ naturæ*, the rule is, that the owner is only liable for mischief done by such animals when he has been guilty of some negligence in keeping such animals; and in practice this amounted to saying, that, if the owner was ignorant that the animal had once before done similar mischief, he would not be liable, unless he had omitted to take some care to restrain that evil propensity. Thus, if a dog or cat, from some sudden whim, chose to attack some person, or other animal, not being incited to it by the owner, such owner is not at common law liable for the first offence; but in case of a second offence, he was generally held liable, at least whenever there was evidence of slight negligence superadded. Hence, if a dog worried sheep casually, the owner was held to be not liable, if it was the first offence. This state of the law was, however, found to work harshly, and a statute passed first for Ireland, then for Scotland, and lastly for England, the effect of which is to make the owner of a dog liable for damages caused by its worrying sheep, even though it is the first offence, and though the owner was not guilty of any negligence.

These statutes passed in 1862, 1863, and 1865 respectively, and they establish an exception to the general rule, which still is in force, as to mischief done by dogs, other than worrying sheep—namely, that before the owner can be made liable, it must be proved that he knew of the dog or cat's mischievous propensity to do the act in question, and did not use due care in restraining it. This is the rule where, for example, a dog bites a person, or a bull gores a passenger. In short, negligence is the gist of the action, and more than mere ownership must be proved against the owner. Sometimes owners of lands plant spring-guns, traps, and similar implements, with a view to kill dogs, cats, and other vermin straying in such fields. The practice of placing spring-guns and man-traps, with a view to kill poachers, was found once to prevail, and created a great outcry about fifty years ago; and the legality of the practice was questioned, but the judges in England held, that if the man injured was a trespasser, the owner of the land was not liable; consequently, a statute was passed to make it illegal in future to place such engines, except in, and close to, dwelling-houses.

In Scotland, the judges held that the practice was illegal at common law, and no statute was necessary. But though man-traps put in fields are now illegal, traps which destroy dogs or cats are not so, with this qualification, however, that the traps must not be put near a highway, where the dog or cat might be lured aside when lawfully passing, as this would be taking too great an advantage of the instincts of the animal. As regards the stealing of tame animals, it was a technical defect in the common law of England that the offence of larceny could not be committed upon them; but by statutes, it is provided that in most cases the offence

of stealing or destroying tame animals is punishable either by fine or by imprisonment, in much the same way as larceny is punishable.

TAMERLANE. See TIMUR.

TAMIL′ (more properly spelled *Tamir′*, but erroneously written *Tamul*, and erroneously termed by the earlier Europeans 'the Malabar') is the name of the language earliest cultivated of all the idioms which the Rev. R. Caldwell designates as Dravidian—this term comprising, according to him, besides the Tamil, the Telugu; Canarese; Malayâlam, or Malayârma; Tul′u, or Tul′uva; Toda, or Tuda, or Tudava; Kôta; Gônd; and Khond, or Kund, or Ku. 'The Tamil language,' this learned author says in his *Comparative Grammar of the Dravidian or South-Indian Family of Languages*, 'is spoken throughout the vast plain of the Carnatic, or country below the Ghauts, from Pulicat to Cape Comorin, and from the Ghauts, or central mountain-range of Southern India, to the Bay of Bengal. It is also spoken in the southern part of the Travancore country, on the western side of the Ghauts, from Cape Comorin to the neighborhood of Trivandrum; and in the northern and north-western parts of Ceylon, where Tamil′ians commenced to form settlements prior even to the Christian era, and from whence they have gradually thrust out the Singhalese.

All throughout Ceylon, the coolies in the coffee-plantations are Tamil′ians; the majority of the money-making classes even in Colombo are Tamil′ians; and ere long, the Tamil′ians will have excluded the Singhalese from almost every office of profit and trust in their own island. The majority of the domestic servants of Europeans, and of the camp-followers in every part of the presidency of Madras, being Tamil′ people, Tamil′ is the prevailing language in all military cantonments in Southern India, whatever be the vernacular language of the district; hence, at Cananore, in the Malayâla country; at Bangalore, in the Canarese country; at Bellary, in the Telugu country; and at Secunderabad, where Hindustani may be considered as the vernacular, the language which most frequently meets the ear in the bazaar is the Tamil′. The majority of the *Klings*, or Hindus who are found in Pegu, Penang, Singapore, and other places in the further east are Tamil′ians. . . . . Including Tamil′ians resident in military stations and distant colonies, and the Tamil′ian inhabitants of South Travancore and Northern Ceylon. . . . . the people who speak the Tamil′ language may be estimated at about *ten millions*.' 'Tamil′ includes two dialects, the classical and the colloquial, or the ancient and the modern, called respectively the Shen-Tamil′ and the Kod′un-Tamil′.' The former is the language of poetry and of the ancient inscriptions; it contains fewer words borrowed from the Sanscrit than the colloquial Tamil′, and among these chiefly such as express abstract ideas of philosophy, science, religion, and technical terms of the more elegant arts; and, in general, it so considerably differs from the colloquial Tamil′ that it is almost unintelligible to the unlearned Tamil′ian.

Of all the Indian languages, Tamil′ has the most imperfect alphabet. The latter consists of 12 vowels—viz., *a, â, i, î, u, û, e, ê, o, ô, âi*, and *aû*—and of 18 consonants—viz., *k, ch, t′, t, p, R, ng, ñ, n′, n, m*, a final *n, y, r, l, v, r′, l′*. Compared to the Devanâgarî alphabet of Sanscrit, it is deficient therefore in the vowels *r′i, r′î*, and *lr′i*, though it possesses a short *e* and a short *o*, which the Devanâgarî has not; it has but one sound for *k, kh, g, gh;* for *ch, chh, j, jh;* for *t′, t′h, ′d, ′dh;* for *t, th, d, dh;* and for *p, ph, b, bh*. It is destitute, moreover, of the Sanscrit aspirate *h*, of the Sanscrit sibilants, *s, s′*, and *sh*, and of Anuswa′ra and Visarga. Of combined consonants, which abound in the Devanâgarî alphabet, it admits only the junction of the nasal and the mute, as *n-t, n′-t′*, &c.; double nasals, as *n-n, m-m*, &c.; double surds as *k-k, ch-ch*, &c.; also *t′k, t′p, Rk, Rch, Rp, yy, ll, vv*, and *nR;* of triple consonants, only *r′nd* and *ynd*. If Sanscrit derivatives, therefore, are Tamil′ized, various devices are resorted to in order to separate Sanscrit groups of consonants. Thus, Sanscrit *pra* becomes Tamil′ *pira;* Sanscrit *kr′ishn′a* becomes Tamil′ *kirut′t′ina-n* or *kit′t′ina-n* (*t′t′* instead of *sh*).

The earliest history of the Tamil′ country is still involved in obscurity. From evidence afforded by the language, Dr. Caldwell has drawn a sketch which would tend to show that the un-Aryanized Tamil′ians had 'kings,' who dwelt in 'fortified houses,' and ruled over small 'districts of country;' that they had 'minstrels,' who recited songs at festivals; but that they were without 'hereditary priests,' without 'idols,' and ideas of 'heaven, hell, soul, or sin;' yet that they acknowledged the existence of God, whom they styled *kô*, or king, and erected to his honor a temple which they called *kô-il*, or God's house. Their chief worship, however, seems to have consisted in bloody sacrifices which they offered to 'the devil.' Dr. Caldwell further shows that they were acquainted with the ordinary metals, except tin and zinc, and with the planets known to the ancients, except Mercury and Saturn; that they had medicines, hamlets, towns, ships, and practised the necessary arts of life, such as cotton-weaving and dyeing, though none of the arts of the higher class, as painting, sculpture, &c.; that they knew no astronomy, and were ignorant of philosophy and grammar.

The earliest civilization of the Tamil′ians is traditionally attributed to the influence of successive colonies of Brahmans from Upper India; and the leader of the first colony is said to have been the Rishi (q. v.) or saint *Agastya*, a personage who plays an important part in Brahmanical legends. He is called the first king of the Pândîya kingdom, which was situated near the southern extremity of the peninsula; and by the majority of orthodox Hindus he is believed to be still alive, though invisible to ordinary eyes. His era is supposed to belong to the 6th c. B.C.; though, like all other ancient Hindu dates, this date, too, cannot be fixed with any degree of certainty. Whether the Vedic worship (see VEDA) was ever known in the Tamil′ country, may be matter of doubt; the worship introduced by the Brahmans seems, on the contrary, to have been that based on the incarnations of Vishn′u (q. v.) and S′iva (q. v.), and therefore to belong to an advanced stage of Hinduism. Vaishn′avas, S′aivas, and S′âktas (see INDIA) are the now prevalent sects of the Tamil′ country; for the Jainas (q. v.), who flourished in the Pândîya kingdom, probably from the 8th or 9th c. to the 12th or 13th after Christ, were finally expelled from it; and only a few adherents of this sect may now be met with there.

The oldest Tamil′ works are, however, those written, or claimed to have been written, by the Jainas; and it is a remarkable fact, that at any period of Tamil′ literature few Brahmans have contributed anything to it that may be deemed worthy of preservation. The finest composition which Tamil′ possesses is the *KuRal′* of Tiruval′l′uvar, 'a work consisting of 1330 distichs or poetical aphorisms, on almost every subject connected with morals and political economy.' Dr. Caldwell holds that it is not later than the 9th c. after Christ. A commentary on this work by Parimelar′agar is the most classical production which has been written in Tamil′ by a Brahman. Besides the *KuRal′*, the following works are said to have received the sanction of the Madura College, which, according to tradition, founded by Vams′a S′ekhara for the cultivation of the Tamil′ language and literature, was then probably the most celebrated seat of learning in all Hindustan. Their names are: *Naladiyar, Nanmanikkadikai, Iniyavai Narppatu; Inna Narppatu, Kar Narppatu, Kallavali Narppatu, Tokai, Tirikadukam, Asara Kovai, Pala Moli, Siru Pansa Mulam, Mutu Moli Kanji*, and *Elati*.

For a list of other and later works written in Tamil′, both medieval and modern, embracing the topics of Religion—Protestant theology, Roman Catholic theology, Hinduism, and books published by Mohammedans—Jurisprudence, Philosophy, Science, Arts, Literature, Philology, Geography and History, Periodicals and Newspapers, see the very useful *Classified Catalogue of Tamil′-printed Books, with Introductory Notices*, compiled by John Murdoch (Madras, 1865); and for learned purposes, the invaluable *Comparative Grammar of the Dravidian or South-Indian Family of Languages*, by Rev. R. Caldwell (Lond. 1856).

TA′MMERFORS, a town in the south of Finland, 250 miles (direct line) west-north-west of St. Petersburg. It is situated on a rapid which connects two lakes, and affords motive-power to an extensive cotton-mill employing a large number of hands. There is also a large flax-mill, a fine stocking manufactory, and a paper-mill. Pop. (1880) 10,000.

TA′MMUZ, a word which occurs once in the Bible—viz., Ezek. viii. 14: 'And, behold, there sat women weeping for Tammuz.' The derivation of the word is as problematic as is the meaning itself. The Vulgate (all the other versions give the word unchanged—thereby confessing the universal ignorance on the subject) has Adonis, and this has indeed been accepted as the most credible explanation of this strange name. It probably means the Phœnician god Adonis, whose chief temple and worship was at Byblus, but who at an early period had been introduced into Syria, Cyprus, and Greece, where he was connected with Aphrodite. His festivals were partly the expressions of joy, partly of mourning. In the latter, the women gave themselves up to the most unmitigated grief over the 'lost Adonis,' shaved off their hair, and sacrificed their chastity in his temples. The days of mourning were completed by a solemn burial of an image of the god. This period was followed by a succession of festive and joyful days, in honor of the resurrection of Adonis. The river Adonis (Nahr Ibrahim) (see PHŒNICIA), which once a year 'ran purple to the sea' from the Lebanon, was supposed to be tinged by the blood of the god; and a vessel sent off from Alexandria, and carried by the tide to Byblus, used to inform the mourners by letter that he had been found again.

There is no doubt that the different phases of the year, or rather the disappearance and reappearance of the enlivening rays of the sun, and their influence upon all nature (see OSIRIS), were symbolized in these originally poetical, afterwards licentious and fanatical rites. The time of the year at which these feasts were celebrated, has given rise to much dispute. Most probably, they

took place at the summer solstice; and the designation of a Hebrew month as Thamuz—which falls about our August—seems further to favor this opinion.

TAMMY, a thin worsted stuff, highly glazed. It is much used for ladies' boots, under the name of *Lasting;* it is also called *Durant*. It is also used, undyed, to form sieves for use in cooking, to strain sauces. Such sieves are called Tammies, or Tamis.

TAMP, TAMPING. See MINES and BLASTING.

TAMPAN, a Tick (q. v.) of South Africa, remarkable for its very poisonous bite, found in Angola, and the country southward from it, and described by Livingstone in his *Travels*. It attacks by preference the parts between the fingers or toes. It attains the size of a pea, and when it has satiated itself with blood, is of a dark-blue color, and its skin so tough, that it cannot be burst by squeezing with the fingers. The first effect of the bite is a mingled sensation of pain and itching, which ascends the limb until it reaches the abdomen,and soon causes either violent vomiting and purging, or fever. The tingling sensation lasts for a week.

TAMPI'CO, or Santa Anna de Tamaulipas, a seaport of Mexico, in the state of Tamaulipas, on the Panuco, 5 miles from its mouth in the Gulf of Mexico. Its streets are broad and regular, and among other institutions it contains a custom-house. At the mouth of the river is a dangerous bar, and the harbor is unsafe. Hides, tallow, bones, and salted meat are exported to Great Britain and the United States. The annual imports amount to about £668,000; the exports—greatly reduced within recent years by the state of anarchy and confusion into which the country has been plunged—to £235,000.

TA'MPION, the wooden plug placed in the mouth of a piece of ordnance to preserve it from dust and damp.—In Naval Gunnery, the tampion is the wooden bottom for a charge of grape-shot.

TAM-TAM, an Indian musical instrument, resembling the Tambourine (q. v.), but larger and more powerful, and oval instead of round. It has been occasionally introduced into orchestral bands.

TAMUS. See BYRONY.

TA'MWORTH, a parliamentary and municipal borough, partly in the county of Stafford, partly in that of Warwick, at the confluence of the Tame and Anker, 7 miles south-east of Lichfield. Of the ancient church, the transepts are Norman; the remains of the ancient castle, to which modern additions have been made, are in various styles. Brickmaking, brewing, dyeing, wool-stapling, and manufactures of tapes and small wares are carried on. There is a bronze statue to the late Sir Robert Peel, erected in 1852. Pop. (1881) of municipal borough, 4888; of parliamentary borough, 14,098.

TA'NAGER (*Tanagra*), a genus of birds of the Finch family (*Fringillidæ*), having a conical beak, triangular at the base; the

Tanager (*Tanagra cyanocephala*).

upper mandible notched towards the tip, and its ridge arched. The species are numerous, and the Linnæan genus has been divided into a number of genera, all of which possess the characters just given, and popularly receive the name Tanager. All of them are American, and most of them belong to warm regions; but some visit more northern parts of America as birds of passage. Many of the tanagers are birds of very beautiful plumage, and many have good powers of song. The ORGANIST T. (*T.* or *Euphonia musica*) is particularly famous for its rich full tones.

TANANARIVO. See ANTANANARIVA.

TANCRED, a Sicilian prince, the son of Eudes, a Norman baron, and of Emma, the sister of Robert Guiscard (see GUISCARD), was one of the celebrated heroes of the first crusade, and was born after the middle of the 11th c. A.D. Some chroniclers profess to detail the events of his early life, describing him as the most accomplished youth of his time in athletic and military exercises, and of a wisdom far surpassing that of men of mature years, and as a partisan of his cousin Bohemond (q. v.) in the quarrel with their uncle, Roger ((q. v.) of Sicily. But the first authentic information respecting him is that he raised a large body of men in Apulia and Calabria, and joined Bohemond, then on his way to the first crusade. The two cousins landed in Epirus, and first one and then the other made their submissions to the Greek emperor, Alexis. T.'s exploits on the way to Syria; his quarrel with Baldwin for the possession of Tarsus, and his subsequent chivalrous forbearance to, and rescue of, his rival; his wondrous valor before Antioch, where he killed no fewer than 700 infidels, transmitting the heads of 70 to the pope, and receiving a corresponding number of marks of silver in return; his vigorous repulse of the first sortie by the infidels from Jerusalem, his sad and lonely vigil on the Mount of Olives; and his gallantry at the storming of the sacred city, are all detailed by the numerous chroniclers of this epoch, in their usual style of extravagant laudation, but with a harmony which speaks favorably for their correct appreciaton of his character. He was one of the claimants of the throne of Jerusalem, and was pacified by Godfrey (q. v.), the successful competitor, with the gift of some towns in Palestine, and the principality of Galilee or Tiberias. A brief quarrel with Baldwin, after Godfrey's death, petty combats with the infidels, and occasional wars with the other Christian princes who had settled in Syria and Palestine, occupied the remainder of his life, which was brought to a close at Antioch in 1112.

TANGANYIKA, a lake of Eastern Central Africa, lying between lat. 3° and 9° S. Long. of center, 30° E.; length about 400 m.; breadth, from 15 to 60 m. It was discovered by Speke and Burton in 1858. Cameron surveyed the S. and W. coasts in 1874, and discovered an outlet, the Lukuga, on the W. side. In 1876 Stanley satisfied himself that this channel, which he proved to communicate with the Lualaba or Upper Congo, is generally dried up in certain parts of its course, and only carries the overflow of T. westward at intervals of years. Thomson re-affirmed the connection between T. and the Congo by the Lukuga. Mr. Hore who spent above two years on the shores of the lake, found the height of the surface in March 1879 to be 2700 feet above sea level; in August 1880 the water had fallen 10 feet 4 inches. Mr. Hore believes that the lake had gradually for several years been rising to the former, apparently its highest level, that the obstructions in the Lukuga had then been carried away, and so the water had found its way to the Congo. Except when several rainy seasons follow one another, the evaporation keeps the water about the same level. See the *Proceedings of the Geog. Soc.*, 1882.

TANGENT. See TRIGONOMETRY.

TA'NGHIN (*Tanghinia venenifera*, or *Cerbera Tanghin*), a tree of the natural order *Apocynaceæ*, a native of Madagascar. The fruit is a drupe, of which the kernel is so deadly a poison, that although not larger than an almond, one kernel is sufficient to destroy twenty people. It was used in Madagascar as an ordeal for the discovery of guilt or innocence, and with the general result of the death of those subjected to it. A little of the powdered kernel was placed on the tongue of the suspected person, and he was obliged to swallow it. Only those recovered whose stomachs quickly rejected the dose. The progress of Christianity and civilization in Madagascar has led to a discontinuance of the use of this ordeal. A similr poison-ordeal is used in some parts of Africa. See ORDEAL and ERYTHROPHLÆUM.

TANGIE'R, a seaport of Morocco, on a small bay or inlet of the Straits of Gibraltar, 38 miles south-west of the town of that name. It is a small, ill-built town, situated on two hills; the houses—with the exception of the residences of foreign officials—being, as a rule, miserable edifices, and the streets being narrow and dirty. The town is surrounded by old walls, and protected by several forts. It has an extensive shipping trade—the annual value of the entering and clearing cargoes being, according to recent accounts, above £600,000. T. was taken by the Portuguese in 1471, ceded to the English in 1662, and held by them for 22 years. Pop. about 9500.

TANGLE, the common name of *Laminaria digitata* and *L. saccharina*, two species of sea-weed, natives of the British shores, growing on rocks in deep water. The stem is woody, the frond leathery, flat, and without a midrib. The woody stems are sometimes used for knife-handles, the blade being stuck in when the handle is soft, and held fast by its shrinking as it dries. The young stalks form an article of food, and are nutritious, owing apparently to the large quantity of gelatinous matter which they secrete. They are also used for feeding cattle. *L. potatorum*, a large species, supplies the aborigines of Australia with instruments, vessels, and food.

TANIS, the Tyrian name of the goddess Astarte (q. v.).

TA'NISTRY, an ancient Celtic custom of succession, which is generally described as devolving the right to inherit lands or honors on the oldest and worthiest of the blood. The tanist, or

righdomna, was the heir-apparent of the monarchy, whom it was the practice to appoint during the lifetime of the sovereign; and there is no doubt that the nearest to the original stock was held to have a preferable claim, as contended by Bruce in his claim to the Scottish throne. The practice of electing a successor was also applied to the inheritance of land, and to succession to ecclesiastical offices.

TANJU'R, more commonly written TANJORE, an important town of India, in the presidency of Madras, 180 miles south-south-west of the city of that name, in the midst of an extensive plain, on one of the branches of the delta of the Kaveri. The town comprizes two forts and several suburbs. The former are so connected that they may almost be regarded as one. The smaller of the two is a parallelogram in shape, and 600 yards in extreme length. It is joined on the north to the larger fort, which is circular in shape, and 1100 yards in greatest diameter. The walls of both are lofty and strong, and are surrounded by a ditch cut out of the solid stone. The principal edifices of T. are the Great Pagoda, esteemed the finest specimen of a pyramidal temple in Hindustan (see INDIAN ARCHITECTURE), and the palace of the rajah. Silks, muslins, and cottons are manufactured. Pop. (1871) 52,175.

The province of Tanjúr, of which the town of the same name is capital, has an area of 3735 sq. m., and contained, in 1871, 1,975,042 inhabitants.

TANK-WORMS. The mud in Indian tanks has been found to abound in *Filariæ*, some of which closely resemble the guinea-worm infesting the human body. Although there is no positive evidence, there is extreme probability that these tank-worms are the origin of the guinea-worm. Dr. Carter, who has had much personal observation of the guinea-worm in India, 'argues, and apparently with good reason, *No tank-worm, no guinea-worm.* Persons who bathe in water in which the former is found may expect to have the latter.' Mr. Bastian, who has written an excellent paper on the anatomy of the guinea-worm, states that there is an undoubted anatomical relation between it and the tank-worm. The real difficulty in the theory is that these tank-worms are widely diffused, while the guinea-worm is restricted in its localization.

TANNAHILL, ROBERT, was born on the 3d June 1774, at Paisley, where his life was almost entirely passed in the humble occupation of a weaver. Very early he exhibited a taste for poetry, and out of his constant study of the works of Burns, Fergusson, and Ramsay, the ambition was developed in him of emulating these favorite authors. His poetry soon became known, and procured him a local celebrity, which, on the publication, in 1807, of a collection of his pieces (*Poems and Songs;* new and larger ed., with a memoir of the author, Glasgow, 1838), was ratified by a wider acceptance. But whilst his modest fame was extending itself, his life had an abrupt termination. He was found one morning (May 17, 1810) drowned in a canal near Paisley; and there seems almost no reason to doubt that his death was that of the suicide. A morbid melancholy which seems to have been inherent in his nature had gradually been growing upon him, and clouding his life with hopeless gloom. He died at the age of 36.

As a song writer, T. continues to be remembered; and some few of his best pieces have established themselves as part of the musical repertory of the Scottish people. He has a genuine lyrical gift, much tenderness of sentiment, and a true eye and feeling for the simple effects of nature with which he was familiar. Of the force and passion of Burns, he has nothing; but in grace and sweetness, Burns himself has scarcely perhaps surpassed certain of his happier passages.

TANNHÄUSER, the subject of one of the most attractive German legends of the middle ages, is a knight who, in the course of his travels, comes to Venusberg (q. v.), and enters the cave-palace, to behold the wonders of the Lady Venus and her court. After having lived there for some time in every kind of delight, his conscience smites him. Invoking the Virgin Mary, he obtains leave of absence, and makes a pilgrimage to Rome, to Pope Urban, to seek, through confession and penance, remission of his sins, and escape from damnation. But the pope, who happens to have a wand in his hand, tells him that he can as little obtain God's mercy as that dry wand can become green again. Thereupon T. departs in despair, and returns to the Lady Venus in the mountain. Three days afterwards, however, the wand begins to sprout and bear green leaves; and the pope immediately sends out messengers to every country, but in vain—T. can nowhere be found. Such is the story, as told in the popular ballad once common all over Germany, and even beyond it, and sung in the district of Entlibuch as late as the year 1830—the best version of which is in Uhland's *Alte hoch- und niederdeutschen Volkslieder* (Stuttg. 1845). In the preface of the *Heldenbuch*, it is further added that 'the faithful Eckhart'—a character in German heroic legends—sits before the mountain, and warns the people of its dangers. In this shape, the story may be traced as far back as the 14th c.; but the substance of the legend is much older, and goes back to the days of German paganism. Some traditions connect it with the Hoselberg or Hörselberg, near Eisenach, in which the Lady Holle or Holda (see BERCHTA) held her court, who, on her part again, seems to be identical with Freyja, the Scandinavian Venus.

The peculiar mythological meaning of the saga, which has numerous points of contact with many other German traditions, has, however, never yet been thoroughly inquired into. Grimm sees in it a touching portrayal of the regret that lingered in the popular heart after the departing paganism, and of the sternness of the Christian priesthood in regard to it. Compare Kornmann, *Mons Veneris* (Fkf. 1614); Grässe, *Die Sage vom Ritter Tannhäuser* (Dres. and Leip. 1846). In later times, the saga has been put into poetical form, among others by Tieck, and made use of by R. Wagner in an opera. This idea of subterranean palaces in which the king or queen of dwarfs, pigmies, fairies, and so forth, held their court, seems to have been universal. Everywhere, stories are told of men being enticed to enter, and finding it difficult or altogether impossible ever again to obtain their liberty. See RHYMER, THOMAS. The visit of Ulysses to the isle of Calypso, and that of Circe, appear to be only modifications of the same idea.

About the middle of the 13th c., and contemporary with Pope Urban (Urban IV., 1261—1265), there lived in reality in Germany a Bavarian knight named Tannhäuser, who, as Neidhart relates, after returning from the wars, resided as Minnesinger (q. v.) at the court of the Austrian Duke Frederick II. the Quarrelsome. At the duke's death, and after having wasted his substance in dissipation, he resided partly with Duke Otto II. of Bavaria, and partly led a wandering life. T. has composed fine spirited ballads, which, however, show the decay that had already set in in the Minnesinger's art. T.'s memory was held in high regard by the Meistersingers, who also preserved one of his measures; and it is quite possible that this T. may have been introduced into popular fiction, and have had his name worked into a myth, in which there is some resemblance to his actual fortunes; in which process, however, that old myth became transformed into the more modern saga. The poems of T. are published partly in the second part of the *Minnesinger* (published by Von der Hagen, Leip. 1838), and partly in the sixth vol. of Haupt's *Zeitschrift für deutsches Alterthum* (Leip. 1848).

TA'NNIC ACID, or TANNIN. Under these synonymous terms, chemists include a number of solid non-nitrogenous substances, consisting of carbon, hydrogen, and oxygen, some of which are crystalline, and others amorphous, and possessing no smell, but a well-marked astringent taste. They are soluble in water and alcohol, the solutions being acid, and yielding precipitates with most metallic oxides. A solution of gelatine is also precipitated by a solution of any of the tannic acids, and the gelatigenous tissue in raw hides is by an analogous process converted into leather. See GALLOTANNIC ACID. None of these acids are volatile; and when exposed to the action of heat, they decompose, and yield the so-called pyro-acids. The persalts of iron yield bluish-black or green precipitates with the tannic acids.

The members of this gronp are widely diffused throughout the vegetable kingdom. 'The bark and leaves of most forest trees, such as the oak, the elm, the willow, the horse-chestnut, and the pine—and of many fruit trees, such as the pear and plum, contain tannin in notable quantity. The wood and bark of many shrubs, such as the sumach and whortleberry, and the roots of the tormentilla and bistort, are also powerfully astringent, owing to the presence of one of the forms of tannin. Coffee and tea, as well as Paraguay tea, likewise contain a modification of this principle. All these bodies, except coffee, precipitate the persalts of iron of a bluish-black color; or, if a free acid be present, the solution assumes a dark-green color.'—Miller's *Organic Chemistry*, 2d ed. p. 400.

The variety of tannin, or tannic acid, occurring in catechu and kino, produces a green precipitate with the persalts of iron; while that occurring in matricaria, rhatany, and the common nettle, produces a gray precipitate. The principal members of this group are—1. *Gallotannic acid* or *Tannic acid*, $C_{54}H_{22}O_{34}$ (in the ordinary acceptation of the word), which is mainly obtained from the gall-nut, and has been described in a special article; 2. *Moritannic acid*, $C_{28}H_{16}O_{20}$, obtained from fustic (*Morus tinctoria*); 3. *Quinotannic acid*, $C_{20}H_{18}O_{17}$, obtained from cinchona bark; 4. *Quercitannic acid*, from oak bark; 5. *Mimotannic acid*, $C_{54}H_{24}O_{24}$, from catechu; and 6. *Kinotannic acid*, from kino; to which some chemists add a variety occurring in coffee and Paraguay tea, to which the term *Caffotannic acid* is given.

TANNING. See LEATHER.

TANSY (*Tanacetum*), a genus of plants of the natural order *Compositæ*, sub-order *Corymbiferæ*, allied to *Artemisia* (q.v.), and having hemispherical heads of flowers, with the florets all tubular, the receptacle naked, the pappus a slight membranous border.

The species are pretty numerous, and are natives of the temperate parts of the Old World.

COMMON T. (*T. vulgare*) is a native of Britain and of Continental Europe, growing in fields and by roadsides, river-banks, &c. It has long been generally cultivated in gardens. It is now naturalized, and pretty common in many parts of North America. It

Tansy (*Tanacetum vulgare*).

is a perennial, from two to four feet high, with great abundance of deep-green, bipinnatifid, inciso-serrate leaves; the flowers in terminal corymbs, yellow, and rather small. The leaves and flowers have a strong aromatic smell and a bitter taste. The young leaves are used for flavoring puddings, cakes, omelets, &c. The plant is also tonic and anthelmintic, and *Tansy tea* is an old popular medicine. Some curious old customs still linger in many parts of England connected with the use of *Tansy cakes* and *Tansy puddings* at Easter, which was originally intended to represent the use of bitter herbs at the Paschal feast. In some parishes of the counties of Devon and Dorset, the clerk carries round to every house a few white tansy cakes as an Easter offering after divine service on Good Friday, and receives a gratuity from each householder. In former times, both ecclesiastics and laics played at ball in the churches for tansy cake at Easter-tide. The highest dignitaries took part in this, and began the ball-playing, which went on during the antiphone, and was accompanied with dancing. After the ball-playing was over, all retired for refreshments; and a gammon of bacon was a standard dish, to signify abhorrence of the Jews. A tansy pudding was an essential part of the feast. —See Chambers's *Book of Days*.

TA'NTALUM (symb. Ta, new equiv. 182) is a very rare metal, discovered in 1802 by Ekelberg in the Swedish minerals known as tantalite and yttrotantalite. It is so closely allied to columbium or niobium, that Wollaston regarded the two metals as identical, a view which was generally adopted till Rose disproved it. As it is of no practical importance, it is unnecessary to enter into any details regarding it.

TA'NTALUS, a character noted in Greek mythology for the punishment he suffered in the lower world. He is said to have been the son of Zeus by Pluto, and some accounts describe him as king of Argus or Corinth. Various reasons are assigned for his undergoing the severe punishment which he did, the most common being, that he divulged the divine councils of Zeus, which the latter had communicated to him as secrets. In the lower world, he was afflicted with an insatiable thirst, and had to stand up to the chin in a lake, the waters of which receded whenever he tried to drink of them. Clusters of fruit hung over his head, which eluded his grasp whenever he endeavored to reach them, his mind at the same time being kept in a state of constant terror lest a huge rock, suspended above his head, and ever threatening to fall, should crush him. T., or rather the punishment which he suffered, has supplied the English language with the very significant verb, 'tantalize.' T. was the father of Pelops, Broteas, and Niobe.

TANTALUS, a genus of birds of the family *Ardeidæ*, resembling storks in their feet and bill, except that the ridge of the bill is rounded, and its tip gradually curved downwards, and slightly notched on each side; a portion of the head, and sometimes of the neck, is bare. The AFRICAN T. (*T. ibis*) was long regarded as the Ibis (q. v.) of the ancient Egyptians, but it is rare in Egypt, and belongs chiefly to Senegal. It is much larger than the true ibis. The AMERICAN T., or WOOD IBIS (*T. loculator*), is as large as a stork, but more slender, white, with black quill and tail feathers, the naked skin of the head and neck black. It is found both in North and in South America. In the United States, it chiefly inhabits the swampy districts of the south.

TANTRA (from the Sanscrit *tan*, to believe, to have faith in; hence, literally, an instrument or means of faith) is a name of the sacred works of the worshipers of the female energy of the god S'iva. See S'AKTAS. A Tantra is said to comprise five subjects —the creation and destruction of the world, the worship of the gods, the attainment of all objects, magical rites for the acquirement of six superhuman faculties, and four modes of union with spirit by meditation. A variety of other subjects, however, are introduced into many of them, whilst some are limited to a single topic, as the mode of breathing in certain rites, the language of birds, beasts, &c. They always assume the form of a dialogue between S'iva and his wife, in one of her many forms, but mostly as *Umâ*, or *Pârvatî* (q. v.), in which the goddess questions the god as to the mode of performing various ceremonies, and the *mantras*, or prayers and incantations to be used in them. These he explains at length, and under solemn cautions that they involve a great mystery, on no account whatever to be divulged to the profane.

The efficacy of these *mantras* is deemed to be all-powerful, and according to some Tantras, that of the faith in these revelations of S'iva so great, as to free a believer from the consequences of even the most atrocious sins. The followers of the Tantras profess to consider them as a fifth Veda (q. v.), and attribute to them equal antiquity and superior authority. Though such an antiquity, or even one approaching the age of the four Vedas, is entirely imaginary, the question of their date is nevertheless involved in obscurity. As Tantras are referred to in some of the *Purân'as* (q. v.), they must have preceded these; but as, on the one hand, the age of the Purân'as themselves is merely conjectural, and as there probably existed older Purân'as than those we possess now; and, on the other hand, as there might likewise have been older Tantras, from which the works now so called were compiled, the circumstance that Tantras are quoted by some Purân'as would not throw much light on the date of those now extant. It seems more significant, however, that the oldest known author of a glossary of classical words, Amarasinha (see *Lexicography*, under SANSCRIT LITERATURE), should have omitted from amongst the meanings he assigns to the word *tantra*, that of 'a sacred book;' whereas the later commentators on his work do not fail to supply this omission, which certainly would have been an extraordinary one had Tantras existed at the time of Amarasinha.

If, then, this negative evidence has the value which it seems to have, the Tantras would, at all events, be later than the first centuries of the Christian era. The works of this class are very numerous, and it is to be regretted that Sanscrit philology, which has already investigated, more or less profoundly, nearly all the branches of Sanscrit literature, should hitherto have almost entirely neglected this particular branch of it. The principal Tantras are the *S'yâmârahasya*, *Rudrayâmala*, *Mantramahodadhi*, *S'âradâtilaka*, and *Kâlikâtantra*.—See H. H. Wilson, *A Sketch of the Religious Sects of the Hindus*, Works, vol. i., edited by Dr. Rost (Lond. 1862).

TA'NTUM E'RGO, the hymn uniformly sung in the Roman Catholic Church at benediction with the Holy Sacrament. These are the first words of the penultimate strophe of the hymn *Pange Lingua*. The *Tantum Ergo* is the most popular of all the Eucharistic hymns of the Roman Catholic Church.

TANZIMAT, or TANSIMAT, the plural of the Arab word *tansim*, generally signifies 'regulations,' but in a special sense denotes the organic laws established by the Hatti-Sherif of Gulhane, in accordance with which the administration of the Turkish Empire is carried on. These organic laws, the first attempt at constitutional government in Turkey, were published by Sultan Abdul-Medjid in 1844, and treat of—*1st*, the political organization of the empire, and the powers and jurisdiction of the chief officials and higher courts; *2d*, administration and finance; *3d*, justice; *4th*, military affairs. But the tanzimat was a dead letter, or nearly so, except in connection with the army; so that on 7th September 1854, the sultan found it necessary to publish a new ordinance, in which the complete carrying out of the tanzimat in all respects was commanded; and a commission was appointed to see that this was done.

TAORMI'NA (anc. *Tauromenium*), a town on the east coast of Sicily, province of Messina, situated on a narrow ledge of rock, 900 feet above the sea, about 30 miles S.-W. of Messina. It consists mainly of a single street, more than a mile in length, is surrounded by a Saracenic wall, has numerous convents and churches, many picturesque palaces and mansions built in the middle ages, and numerous relics of antiquity, among which are very fine sepulchres, an aqueduct, tesselated pavements, remains of a 'Naumachia' and of a theater, the last reckoned one of the most splendid ruins in Sicily, and commanding a view of almost unparalleled magnificence. T. has some trade in wine and hemp, and a population (1872) of 3004.

Ancient *Tauromenium* was built after the destruction of Sicilian

Naxos in 403 B.C., but the exact date is uncertain. It rapidly attained prosperity.

TAOUISM, the religious system founded by LAOU-TSZE (q. v.; and see CHINA).

TAPA'JOS, an important river of Brazil, and an affluent of the Amazon, is formed by the confluence of the Arinos and the Juruena, both of which rise in the south of the province of Matto Grosso. After a northward course of upwards of 1100 miles in length, the T. falls into the Amazon, about 20 miles below the town of Santarem. In lat. about 7° 30′ S., it has a fall of 30 feet; but the interruptions to the navigation, which is said to reach to within a short distance of the source of the river, are few. A portage of only 18 miles separates the upper waters of the T. from those of the Paraguay.

TA'PESTRY (Fr. *tapisserie*), a kind of carpet-work for decorating walls and furniture. The art of working tapestry is extremely ancient, but we have little information about it until the time of the Saracens, who revived it, and brought it into notice. They, in all probability, only used tapestry as drapery or curtains for the courts of their houses; its use as a covering for walls seems to have been an invention of the Flemings previous to 1606, at which date it was introduced into France by Henry IV., who engaged Flemish artists to teach it. At that period, so generally was its origin attributed to the Saracens, that it was called *Sarrazinois*. The oldest piece in existence is that described under the name of the BAYEUX TAPESTRY (q. v.).

At first the Saracenic tapestries were only ornamented with flowers and geometric figures; but the Flemings aimed higher, and sought to enrich them with historic subjects of the highest order; and so important did this art become, that the most eminent masters in painting, from Raphael downwards, bestowed their greatest efforts upon cartoons to serve as copies for the tapestry-workers, of which the celebrated Raphael cartoons, formerly at Hampton Court, now in a gallery specially designed for them in the Kensington Museum, are illustrations (see CARTOON). After its first introduction into France by Henry IV. at the beginning of the 17th c., the art of making tapestry does not appear to have made much progress until the middle of that century, when a small establishment founded by the brothers Canaye on the premises formerly occupied by Jean Gobelin, a dyer of wool, was commenced, and was afterwards carried on by a Dutchman named Gluck and his assistants with such success, that it was suggested by Colbert, the minister of Louis XIV., that it should be taken under the king's patronage; in consequence of which the establishment was bought, and constituted a royal manufactory in 1667, under the management of M. Lebrun, who was the first director. A royal carpet-manufactory had been previously established in 1615; this was called La Savonnerie, from the previous use of the buildings for the manufacture of soap.

The Savonnerie and the Gobelins were both carried on with great spirit by successive sovereigns, and were formed into one establishment in 1826, when the works of the Savonnerie were removed to the Gobelins, where this most interesting work is now carried to great perfection, and also at a minor establishment at Beauvais, in the department of Oise, where it is, however, worked in a different style and manner. At the Gobelins, a series of threads are arranged vertically in a frame like the warp of a loom and the workman stands behind the frame, the pattern being placed behind him for reference. To produce the design, he has a number of wooden needles threaded with wool and silk of the colors required, and these are passed through the upright warp-threads, and brought back, so that each thread becomes covered with the necessary color; and such is the extreme nicety with which this is done, and such the delicacy and multiplicity of the shades of color employed, that but little difference can be detected between the tapestry picture and the painting from which it was coped. At Beauvais, the warp is placed horizontally, and the workman stands over it; this renders it necessary to cut off the ends on the upper surface, which is avoided in the other plan of working from behind. The Beauvais is, however, a style intermediate between tapestry and carpet-work, and the roughness of surface so produced has a good effect. Much fine tapestry was employed in former times in decorating the palaces and mansions of Great Britain, in many of which it is still seen in great beauty. The modern works of the Gobelins were distributed as presents by the late imperial government of France. They are not produced in great numbers, and are of great money value. The number of artists employed is about 120.

TA'PEWORM, is a word popularly used in a vague sense to designate any worm of the group *Cestoidea* (see CESTOID WORMS). According to Dr. Cobbold, upwards of 250 distinct forms of cestoid worms have been described, of which probably somewhat less than 200 may be regarded as really good species. These he divides into the three families of (1) *Tæniadæ*, or true tapeworms; (2) *Bothriocephalidæ*, and (3) *Tetrarhynchidæ*. For the natural history of the tapeworms generally, we must refer to the article

CESTOID WORMS. We will here only remind the reader of the following points necessary for the due understanding of this article, and that every T. passes through several distinct phases during its life-history. 'In the ordinary colonial or tapeworm condition, says Dr. Cobbold, 'it has been termed the *strobila* (Van Beneden). The separate joints of which the strobila is composed are denominated *proglottides*, or zooids. The anterior segment forms the *head*, and remains barren, those of the neck and front part of the body being sexually immature during the process of strobile-formation. The mature proglottides at the caudal end are capable of realizing an independent existence, and the eggs which they contain develop the six-hooked embryos, or *proscolices* (Van Beneden), in their interior. These latter become metamorphosed into *scolices* or nurses, representing the well-known cysticercal state, which, in its sterile or aborted condition, forms the common *hydatid*.'—*Entozoa*, p. 105. During the greater part of their existence, the tapeworms are parasitic animals, the mature proglottides and eggs being free only during a comparatively short interval. They are mostly restricted in their distribution to the vertebrate animals, comparatively few of the invertebrates (excepting the cuttle-fish) appearing to harbor them in their adult condition, although the T. larvæ, nurses, or *scolices* probably abound in various invertebrate groups.

In the human body, no less than ten species of T. occur, viz., eight *true tapeworms*, and two species of *Bothriocephalus*; and as four distinct species have been found in the Barbary ape, it is obvious that errors of diet, due to civilization, are not the cause of these parasites. Amongst the animals with which we are most familiar, the species are plentiful in the common dog (and in true carnivora generally), in rats, and mice. The typical ruminants are almost constantly infested both by mature and immature forms; while the larger pachyderms, and solidungulates (the horse, ass, &c.), harbor only a few adult forms; but only larvæ appear to be known in swine. These worms appear to be as abundant in granivorous birds as in Carnivorous hawks, owls, &c. In the water-birds generally, the adult worms are very abundant, their larvæ existing in the food of such birds, in fishes, molluscs, &c. In reptiles, these worms are extremely rare, although other parasitic worms abound; while in fishes they are very abundant both in the adult and larval forms.

The *Tæniadæ*, or *true tapeworms*, may be distinguished from the other families of the order *Cestoidea* (cestoids or tapeworms in the popular sense) 'by the possession of a small distinct head, furnished with four simple oval or round suctorial discs (suckers), and commonly also with a more or less strongly pronounced rostellum (proboscis) placed at the summit in the median line. This prominence, when largely developed, becomes retractile, and when not in use, is lodged within a flask-shaped cavity, lined by a sheath, and supplied with special muscles; it is also very frequently armed with a single or double crown of horny chitinous hooks, there being occasionally as many as five or six separate circular rows of these organs. Attention to the number, relative size, and disposition of the hooks is often sufficient to determine the particular species. In nearly all cases, the reproductive orifices are situated at or near the margins of the joints which are bisexual.'—Cobbold, *op. cit.*, p. 109. The eight true tapeworms occurring in man are—(1) *Tænia solium*, Linnæus; (2) *T. mediocanellata*, Küchenmeister; (3) *T. acanthotrias*, Weinland; (4) *T. flavopuncta*, Weinland; (5) *T. nana*, Von Siebold; (6) *T. elliptica*, Batsch; (7) *T. marginata*, Batsch; (8) *T. echinococcus*, Von Siebold.

Fig. 1.

1. Head, neck, and upper joints of *Tænia solium* magnified: *a*, the circle of hooks; *b* and *c*, two of the sucking discs; *d*, the neck.—2. One of the lower or sexually mature joints of the same, showing the water-vascular canals, and the branched uterine organ distended with ova.

The *common tapeworm*, *Tænia Solium*, derives its Linnæan title

from the idea that it is always a solitary worm. Although this is commonly, it is not by any means always the case: Küchenmeister has several times found two or three together, and cases are recorded in which 30 and even 40 worms have been expelled from one patient. The full-grown T. (strobila) has been known from the earliest times, and is described by Hippocrates, Aristotle, and Pliny; but its organization and mode of development have only been properly understood during the last few years. The segments of which it is composed vary in size, and number from 800 to 1000, the earlier immature ones being extremely narrow, and the sexually mature joints commencing at about the 450th segment. From 10 to 35 feet may be regarded as representing its ordinary length; its breadth at about the widest part being one-third of an inch. The head, which is seldom seen in the tapeworms exhibited in our museums, although the evacuation of the head with the rest of the worm is not very rare, is very small and globular (about the size of a pin's head), with black pigment ingrained in it.

On examining it with a low magnifying power, it displays four circular sucking discs, in front of which is a conical proboscis, armed with a double crown of hooks, from twenty-two to twenty-eight in each circular row. The head is succeeded by a very narrow neck, nearly half an inch in length, which is continued into the anterior or sexually immature part of the body, in which traces of segmentation first appear in the form of fine transverse lines, which are gradually replaced by visible joints. These joints or segments represent the body, and each mature segment contains both male and female organs of generation; and in addition to these structures, the entire series of joints is traversed by a set of vascular canals constituting the so-called aquiferous system, which consists of two main channels, one passing down on either side of the worm, and both being connected by transverse vessels, which occur singly at one end of every joint. It is only in the alimentary canal of man or some other animal that a T. of any kind can attain to sexual maturity; and in all of these the eggs are fecundated before being discharged.

Fig. 2.
The double crown of hooks more highly magnified.

The expulsion of the eggs may take place in any of the following ways: First, the mature segments separate from each other, and passing out of the body, either with the ordinary evacuation of the bowels or independently, become decomposed, and set free the enclosed eggs. The single joints thus discharged undergo violent contraction after being expelled, which led to their being formerly mistaken for a distinct species of worm, to which the title *Vermes cucurbitini* was applied, from their resemblance to a pumpkin seed. There is a figure in Aitken's *Medicine*, 3d ed. vol. i. p. 815, showing the joints of a *Tænia mediocanellata* (which will be presently described) of the natural size, in various stages of contraction; and on examining the recently discharged excrement of a constipated dog, the same phenomenon may be very frequently observed. Secondly, the eggs may be discharged through the genital pore by pressure from any cause. It is only thus that we can account for the occasional (but very rare) co-existence of a *Cysticercus cellulosæ* (the embryo of the worm) and an adult T. in the intestinal canal of the human subject—an association which constitutes one of the most serious dangers which the matured worm can inflict upon its host, and one of the strongest indications for its removal. Thirdly and lastly, the mature joints sometimes appear to undergo disintegration within the intestine, and to liberate the eggs; but the conditions under which this disintegration occurs are unknown.

In reference to the ultimate fate of the embryos *in ovo*, that are liberated in the intestinal canal, Dr. Cobbold has informed the author of this article in a private communication, that, in his opinion, they do not migrate in the living host, except when by regurgitation they occasionally get into the stomach, when, after their shells have been dissolved by the gastric juice, the young organisms commence their wanderings. The mature segments are usually expelled from the human bowel at the rate of six or eight a day. Their vitality is prolonged by moisture, which favors the distribution of the liberated eggs over grass and other vegetables, or in water, which may be used as food or drink by animals. For a full description of the eggs, we must refer to Dr. Cobbold's work. It is sufficient here to remark, that, in their mature condition, they 'present a globular figure, and are easily recognized by their remarkably thick shell, which surrounds the six-hooked embryo. They present an average diameter of $\frac{1}{64}$th of an inch, the shell itself measuring about $\frac{1}{4000}$th of an inch in thickness. After a while, by accident, as it were, a pig coming in the way of these embryos, or of the proglottides, is liable to swallow them along with matters taken in as food.

'The embryos, immediately on their being transferred to the digestive canal of the pig, escape from the egg-shells, and bore their way through the living tissues of the animal, and having lodged themselves in the fatty parts of the flesh, they there rest to await their further transformations or destiny. The animal thus infected becomes measled, its flesh constituting the so-called measly pork. In this situation, the embryos drop their hooks, and become transformed into the *Cysticercus cellulosæ*. A portion of this measled meat being eaten by ourselves, either in a raw or

Fig. 3,
a, a fully developed *Cysticercus cellulosæ* or *Measle*, taken from fresh pork (natural size); *b*, Cysticercus from salted pork; *c*, the same as *a*, magnified about 3 diameters; *d*, the same as *c*, with the head and body withdrawn from the caudal vesicle.

imperfectly cooked condition, transfers the cysticercus to our own alimentary canal, in which locality the cysticercus attaches itself to the wall of the human intestine, and having secured a good anchorage, begins to grow at the lower or caudal extremity, producing numerous joints or buds to form the strobila or tapeworm colony.'—Cobbold, *Entozoa*, p. 221. In its fully mature stage, the *measle* presents the appearance of an elliptical hydatid, varying in size from that of a pea to that of a small kidney-bean, the average diameter being one-third of an inch. On dissecting or breaking up a measle, it will be seen that the great vesicular portion constitutes the bladder-like caudal extremity of the cysticercus, while the head, neck, and body can be drawn out so as to exhibit a vermiform character.

In the article GENERATIONS, ALTERNATION OF, it was stated that the group of phenomena included in that term would be further illustrated in the history of the tapeworm. From what has been already shown, it appears that 'we have a simple alternation of generation in which the immediate product of the proglottis (or sextually matured zooid individual) is a six-hooked brood; by metamorphosis, the latter becomes transformed into the cysticercus, having a head with four suckers, and a double crown of hooks; and by gemmation, the latter gives rise to a whole colony (strobila) of individuals, the greater part of which are destined to become sexually mature—zooid individuals or proglottides. It will be observed, therefore, that the product of a single ovum is, in the first instance, a single non-sexual embryo; in the second phase, it becomes a non-sexual cysticercus (these two phases together constituting the protozooid); in the third change it gives off, by budding, numerous gemmules, most of them destined to be sexually mature individuals (or deuterozooids), in this way resembling their original parents.

'The relation and nature of these developmental changes may be further simplified by placing the various life phases in a tabulated form as follows:

'(*a.*) Egg in all stages.
(*b.*) Six-hooked embryo = proscolex. } Protozooid.
(*c.*) Resting larvæ or *Cysticercus* (*telæ*) *cellulosæ* (scolex). }
(*d.*) Immature tapeworm.
(*e.*) Strobila, or sexually mature *Tænia solium*.
(*f.*) Proglottis (cucurbitinus) = free segment = deuterozooid.'

—Cobbold, *Entozoa*, pp. 221, 222.

How long a T. can naturally exist in an intestinal canal is not known; but there is doubtless a period at which the parasite spontaneously separates from the intestinal mucous membrane of its host—a period probably coinciding with the shedding and non-renewal of the circlet of hooks. When this separation occurs, the whole length of the worm is expelled in the same manner as if the parasite had been first killed by the administration of a vermifuge medicine. From this history of the structure and life-history of this organism, which applies with slight difference in minor points to all other tape-worms, we proceed to describe the injurious effects which the worm in its adult and larval stages produces on man, and the precautions which should be taken to prevent its entrance into the system; while the discussion of the means of expelling it when it has once found a lodgment in the intestinal canal, will be postponed to the article on VERMIFUGES.

The common T. may cause disease, and even death, by its aggressions, either in the adult or in the larval stage of its existence. A mature T. in the intestinal canal may give rise to a series of anomalous symptoms, including 'vertigo, noises in the ears, impairment of sight, itching of the nose and anus, salivation, dyspepsia, and loss of appetite, colic, pains over the epigastrium and in different parts of the abdomen, palpitation, syncope, the sensation of weight in the abdomen, pains and lassitude in the limbs, and emaciation.'—Davaine, *Traité des Entozoaires*, &c., p. 103. Many cases are on record in which hysterical fits, chorea, epilepsy, convulsions of various kinds, and even mania, have been induced by the irritation excited by this parasite, and have ceased at once on its removal. But distressing as these symptomatic phenomena may be, their injurious effects are trifling as compared with the troubles which follow the deposition and growth of the larval form within the body, especially when the cysticerci find a home in the more important vital organs. There are at least a hundred cases on record in which the cysticercus has caused death by its development within the human brain.

In the present state of our knowledge, it is impossible to diagnose these cases; and even if a correct diagnosis were possible, nothing could be done in the way of treatment. Epilepsy, with or without mania or imbecility, is commonly, but not invariably present in these cases. 'Cysticerci,' says Dr. Cobbold, 'may develop themselves in almost any situation in the human body, but they occur most frequently in the subcutaneous, areolar, and inter-muscular connective tissue; next, most commonly in the brain and eye, and lastly, in the substance of the heart and other viscera of the trunk.'—*Entozoa*, p. 226. The *adult form of the worm* enters the system as the cysticercus of measly pork, and to eat raw or underdone measly pork is an almost certain means of introducing this parasite into the body. It is satisfactory to know that the temperature of boiling water is quite sufficient to destroy the vitality of the measles; and that in ordinary salted pork, and in hams, they are destroyed by the action of the salt in the one case, and of the combined salt and smoke in the other. Sausages, into which it is to be feared measly pork too often finds its way, are rendered safe if they are cooked till no pink, raw like, fleshy look can be seen in their center. Butchers are especially liable to T., in consequence of their touching and cutting measly pork, and then accidentally transferring the cysticercus by the hand, or even by the knife, to the mouth; and by indiscriminately using the same knife for various meats, both butchers and cooks may readily disseminate the infection over various articles of food.

The *larval worm* may gain access into the human body by our swallowing the mature eggs of the tapeworm. Those who, as students of this department of natural history, handle fresh tapeworms, are perhaps especially liable to this misfortune; but, says Dr. Cobbold, 'our neighbors, who devour choice salads, also run a certain amount of risk, not only as regards this entozoon, but as respects several others. The vegetables may be manured with night-soil containing myriads of tapeworm eggs, or they may be watered with fluid filth into which these eggs have been cast. In such cases, one or more tapeworm ova may be transferred to our digestive organs, unless the vegetables are carefully cleansed before they appear on the table. In the same way, one perceives how fallen fruits, all sorts of edible plants, as well as pond, canal, or even river water, procured from the neighborhood of human habitations, are liable to harbor the embryos capable of gaining an entrance to our bodies. It thus becomes evident also how one individual suffering from tapeworm may infect a whole neighborhood, rendering the swine measly, these animals in their turn spreading the disease far and wide.' Such a person may also prove dangerous—even fatal to his neighbors directly (without the intervention of a pig), by ejecting mature proglottides, from which thousands of eggs may escape, some of which may readily come in contact with human food or drink, make their way into the stomach, and from thence get into the circulation, and finally to the brain, where they cause convulsions and death.

The most remarkable case on record of what may be termed a *measly* man, is one described, in 1864, by Delore, in the *Gazette Méd. de Paris*, and quoted by Dr. Cobbold. He died at the age of 77, from pulmonary catarrh, old age, and fractured neck of the thigh-bone; and on examining his body after death, no less than 2000 cysticerci were found, of which 111 occurred in the nervous centers.

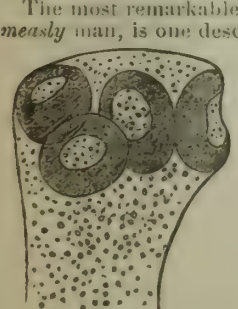


Fig. 4.
Head of *Tænia mediocanellata*, magnified about 35 diameters. (From Cobbold.)

The T. that ranks next in importance to the *Tænia solium* is the *Tænia mediocanellata*, which was first established as a distinct species by Küchenmeister only a few years ago. It exceeds the *T. solium* both as regards length, breadth, and the thickness of the individual segments; the head is also somewhat larger, abruptly truncated at the crown, destitute of a proboscis and a hook-apparatus—hence this species has been described as the *hookless tapeworm*—but furnished with very large sucking-discs, surrounded by much dark pigment, which gives the head a blackish appearance. The specific name of *mediocanellata* has reference to an interesting and almost specific character in connection with the water-vascular system, into which we have not space to enter.

Leuckart has proved by experiment that the measles or cysticerci which produced this worm are to be found in the muscles and internal organs of cattle. He administered proglottides of *T. mediocanellata* to three calves, a sheep, and a pig. In the two last-named animals, they produced no effect, as was shown by their post-mortem examination; while in the calves they produced a kind of leprosy, which has since been characterized as 'acute cestoid tuberculosis,' and which proved fatal if too large a dose of eggs was administered. On examining one of these animals after its restoration to health—48 days after the eggs were swallowed—he found numerous cysticercus-vesicles, larger and more opalescent than those of the pig, lodged within the muscles; and as the heads of the contained cysticerci exhibited the distinctive peculiarities presented by the head of the adult worm, 'we are supplied with the most unequivocal evidence that man becomes infested with this second form of tapeworm by eating imperfectly cooked veal and beef.' Hitherto, the two above-described species have commonly been included under *T. solium*, from want of due examination, especially of the head. Dr. Cobbold believes that their respective frequency will ultimately be found pretty well on a par, though probably the *T. solium* will maintain a slight ascendency, in consequence of the relative cheapness of pork. 'Admitting occasional exceptions,' he observes, 'the hooked worm infests the poor, and the hookless worm the rich. This circumstance accords with the fact, that the lower classes subsist chiefly upon pork, whilst the wealthier prefer mutton, veal, and roast-beef.'—*Entozoa*, p. 243. It gives rise to the same symptoms as the *T. solium*.

The next five tapeworms infesting man may be passed over without notice, as being of very rare occurrence. *Tænia acanthotrias* is only known from a single case, in which, in the larval stage, it was found in the muscles of a woman. The last species we shall describe, the *T. echinococcus*, is, in its larval condition, probably more fatally injurious to the human race than all the other species of entozoa put together. In its mature (strobila) condition, in which it is found only in the dog and wolf, it seldom exceeds the fourth of an inch in length, and develops only four segments, including that of the head. The final segment, when sexually mature, equals in length the three anterior ones, and contains as many as 5000 eggs. The proscolex or embryo forms large proliferous vesicles, in which the scolices or larvæ (known also as acephalocysts, echinococci, echinococcus heads or vesicles, pill-box hydatis, &c.) are developed by gemmation internally. The eggs develop in their interior a six-hooked embryo, and these embryos are introduced into our bodies with food or water into which the eggs have been carried.

'With an especial liking for the liver,' says Dr. Cobbold, 'they bore their way into this organ or are carried along the circulating current to other organs. In these situations, they sooner or later become transformed into simple vesicular, bladder-like bodies, commonly called acephalocysts or hydatids.' Instead, however, of displaying the head, neck, and body of a cysticercus, the vesicle retains a globular figure. Its growth is slow, and many months elapse before echinococci are developed within our bodies, after we have swallowed the proper T. eggs and their contained embryos. There have been great differences of opinion amongst physiologists as to the mode of development of these echinococci; but the following is probably the current view. The inner surface of the vesicle presents after a time slight papillæ or prominences, which, as they enlarge and become oval, are eventually scoleciform, and contain a cavity filled with a limpid fluid. This scolex-like development produces in its interior a brood of scolices or echinococcus heads, or, in other words, becomes gradually transformed into the so-called 'brood-capsules' of helminthologists. It is almost impossible to explain the nature of these brood-capsules, with young echinococci in their interior, without the aid of such diagrams and illustrations as are given by Cobbold in his chapter on *T. echinococcus*.

In the fully developed state, the echinococci vary from $\frac{1}{60}$th to $\frac{1}{100}$th of an inch in diameter. The rostellum supports a double curve of hooks, those in the smaller row varying in size from $\frac{1}{1670}$th to $\frac{1}{1850}$th of an inch, whilst those of the larger series are from $\frac{1}{830}$th to $\frac{1}{1850}$th of an inch. Below the hooks are four suckers, and the general appearance of the body is finely granulated, from its containing calcareous particles. These hooklets are so characteristic and important in diagnosis, that we give a highly magnified representation of them. It often happens that the discovery under the microscope of a few of these little hooks at once decides the nature of an otherwise mysterious tumor. Of 373

cases of the parasite occurring in man, collected by Davaine (who devotes more than one-third of his *Traité des Entozoaires* to this subject), 165 affected the liver, 40 the lungs, 30 the kidneys, 20 the brain, and 17 the bones, while the remainder were spread over other parts; and of 136 cases collected by Cobbold, 51 affected the liver. No less than 35 of these 51 cases recovered. 'Four of them were complete natural cases; two others being also temporarily cured in the same way. All the rest were cured by surgical operations.'

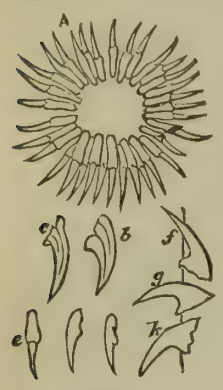

Fig. 5.

A, magnified view of the circle of hooklets seen upon its under surface, thirty-four in number; *b*, *c*, lateral views of the separate hooklets; *e*, hooklets seen on the inferior or concave border; *f*, *g*, *h* illustrates the movements and position of the hooklets, the vertical line running through the fixed point of each of the three hooks.

It is impossible to state with accuracy the degree of prevalence of hydatids in this country, or the extent to which it proves fatal. In Iceland, this disease is endemic to such a degree that about one-sixth of the population are affected with it. It produces a long illness, terminating with a painful death, and no means of cure have yet been discovered. Its prevalence in that island may be rationally accounted for. Firstly, every peasant has, on an average, six dogs, all of which are probably infested by the mature T.; and secondly, there being only six legally authorized medical men, the great majority of the population (over 10,000 persons, scattered over 1500 sq. m.) are in the hands of quacks, whose principal treatment consists in the administration of *fresh dog-excrement!* Our authority for this astounding specimen of homœopathic treatment is Leuckart, whose admirable popular essay, *On the Newest Discoveries regarding Human Intestinal Worms, and their Importance in Relation to Hygiene*, in the *Conversations Jahrbuch*, 1863, is deserving of the most careful study. For an excellent abstract of the remarkable series of experiments by which the relationship between the so-called cystic worms and the cestoid worms was established, we may refer the reader to Aitken's *Science and Practice of Medicine*, vol. i.; while for the subject of T. generally, the highest authorities are the works of Küchenmeister and Siebold, translated by the Sydenham Society; Davaine's *Traité des Entozoaires;* Weinland's *Essay on the Tapeworms of Man;* Cobbold's *Entozoa* (1864), a work equally remarkable for the vast amount of original research which it contains, and for the beauty and correctness of the illustrations; and of Leuckart's *Die Parasiten des Menschen* (Leipzig, 2 vols. (1863—1876), which is the standard work on the subject of the parasites of man.

TAPEWORMS, although rare amongst horses and cattle, are common in dogs and sheep, causing irritability of the bowels, and an unthrifty appearance. For dogs, no remedy answers so well as powdered areca nut, of which 30 grains suffice for a dog weighing about 20 lbs. It is best given after ten or twelve hours' fasting, in a little soup or milk, and should be followed in a few hours by a dose of castor oil. Neither areca nut nor any of the approved remedies used in men, prove effectual in sheep; and one of the best prescriptions for them consists of 40 drops of oil of turpentine, a drachm of powdered green vitriol, and an ounce of common salt, given mixed in a little milk or gruel, or, where their bowels are confined, in linseed oil. A daily allowance of linseed cake and sound dry food should likewise be given with the grass or roots, and pieces of rock-salt left within the animal's reach.

TAPIO'CA. See MANIOC and CASSAVA.

TA'PIR (*Tapirus*), a genus of *Pachydermata*, of the section *Ordinaria;* having a bulky form, with moderately long legs; the fore-feet four-toed, the hind-feet three-toed; the skin thick, the hair short; the tail very small; the neck thick; the ears short; the eyes small; the muzzle elongated; the nose prolonged into a short, flexible proboscis, which, however, does not terminate in an organ of touch and prehension, like that of the elephant; six incisors, two canine teeth, and fourteen molars in each jaw, the molars separated from the canine teeth by a wide interval. The best known species is the AMERICAN T. (*T. Americanus*), which is about the size of a small ass, and is common in almost all parts of South America, its range extending as far south as the Strait of Magellan, although it suddenly ceases to be found at the Isthmus of Darien. Its color is a uniform deep brown, but the young are beautifully marked with yellowish fawn-colored stripes and spots. The skin of the neck forms a thick rounded crest on the nape, with a short mane of stiff hair.

The T. inhabits deep recesses of the forest, and delights in plunging and swimming in water. It feeds chiefly on young shoots of trees, fruits, and other vegetable substances; but is ready to swallow almost anything that comes in its way. Pieces of wood, clay, and pebbles are often found in its stomach. It sometimes commits great ravages in cultivated grounds; a large herd of tapirs sallying forth from the forest by night, trampling and devouring all that they find in the fields. The T. is a very powerful animal, and, protected by its thick hide, forces its way

Malayan Tapir (*Tapirus Malayanus*), and Young.

through the forest where almost no other quadruped can. When assailed by the jaguar, it seeks to get rid of him by rushing through thick underwood, and if it can reach water, is often successful by plunging in and diving. It is inoffensive, never attacking man; but when hard pressed by dogs, makes a violent resistance, and inflicts severe bites. It is very easily tamed, and becomes extremely familiar; but its large size makes it a troublesome pet. Its hide is useful, and its flesh is eaten, although rather dry.—The MALAYAN T. (*T. Malayanus* or *Indicus*) is found in Malacca, Sumatra, &c. It is larger than the American T., and its proboscis is rather longer in proportion. The neck has no mane. The color is glossy black, except the back, rump, and sides of the belly, which are white. The colors do not pass gradually one into another, but the line of separation is marked, giving the animal a very peculiar appearance.

The habits of this species are very similar to those of the American T., and it is equally capable of domestication. The young are striped and spotted as in that species.—A third species is found in the mountainous parts of South America.

The remains of tapirs have been found in Miocene and subsequent strata. In all, about twelve species have been determined. Tapir-like animals are common in Eocene beds. Ten species of *Palæotherium* (q. v.) have been described. *Lophiodon*, of which fifteen species have been observed, differs from *Palæotherium* in the structure of the teeth of the lower jaw—and from other peculiarities in the same organs, *Coryphodon* (containing three species) has been separated from both genera.

The T. is a remarkable exception to the generalization deduced from the comparison of the later Tertiary mammals with those living in the same districts at the present day, viz., that there is a close correspondence between the fauna of the two periods. The Pliocene and Post-pliocene bears, hyenas, tigers, elephants, &c., of Europe and Asia are represented by living species of the same or nearly allied genera. The recent sloths, armadilloes, and prehensile-tailed monkeys of South America were preceded by closely related forms in the later Tertiary period; as were also the marsupials of Australia. Several species of T. have been found in Europe, but they have left no representatives nearer than Eastern Asia and South America.

TAPPING is an operation which is most commonly performed on the abdomen, but occasionally on the chest and head. Tapping of the abdomen gives great relief when the abdomen becomes inconveniently distended with fluid contained in the peritoneal sac, or, in the case of the female, in an ovarian cyst. A small incision is then made about two inches below the navel, through which the cutting surfaces of the trochar—the instrument used in this operation—are passed. By arrangements into which we need not enter, the fluid escapes through this instrument. The wound made by the trochar in the abdomen will, in ordinary cases, heal in a few days.

Tapping of the chest is an operation which is occasionally required for the relief of empyema and other effusions in the cavity of the pleura. Tapping of the head has been occasionally found successful in hydrocephalus. Tapping of the pericardium has been practised in cases of pericardial dropsy, but it is an operation not to be recommended under any circumstances.

TA'PTI, a river of the British presidency of Bombay, India, rises in the Saugur and Nerbuddah territories, in lat. about 21° 46′ N., flows west through Scindhia's dominions and the districts of Candeish and Surat to its mouth in the Gulf of Cambay, 17 miles below the town of Surat. It is 441 miles in length; but can hardly be said to be navigable, for even small vessels of from 40 to 50 tons burden cannot ascend higher than Surat.

TAR is a well-known substance, for which it is difficult to frame a definition, since it varies in composition, color, and consistence, and is derived from all three kingdoms of nature. In various parts of the world, it occurs as a natural mineral product, and is known under the various names of bitumen, asphalt, petroleum, natural tar. See NAPHTHA. As an animal product, a species of tar is obtained from the destructive distillation of bones employed in preparing bone-black. The distillate, which possesses a most offensive odor, separates into a heavier layer of black animal tar—commonly known as *bone-oil*, or *Dippel's Animal Oil*—and a lighter layer of watery solution of sesquicarbonate of ammonia, commonly known as *bone-liquor*, and much employed in the preparation of various salts of ammonia. This animal tar is chiefly used for the lubrication of machinery. The vegetable kingdom is, however, the most important source of tar. On submitting wood to destructive distillation in closed vessels, we obtain a large number of products, which are described in the article WOOD, DISTILLATION OF; some are gaseous and some liquid, and of the latter one portion is soluble and the other insoluble in water. This insoluble portion constitutes wood-tar, and is composed of a mixture of various liquids holding solid matters in solution or in suspension.

Amongst its most important constituents, Professor Miller mentions several forms of hydrocarbon, such as toluol, $C_{14}H_8$; xylol, $C_{16}H_{10}$; cymol, $C_{20}H_{14}$; and eupion, besides a number of oxidized compounds, including creasote, $C_{24}H_{16}O_4$, picamar, and kapnomar, $C_{20}H_{11}O_3$; whilst among the solid portions are resinous matters resembling colophony, and a waxy substance named paraffin, and many other substances, such as napthalin, cedriret, pittacal, pyrene, $C_{30}H_{12}$; chrysene, $C_{12}H_4$; and pyroxanthin. (When the formula is not given, the exact composition of the substance is not determined with certainty.) The *Stockholm tar*, which is so widely used in ship-building, and the *American tar*, which is almost equally celebrated, are chiefly prepared from the resinous wood of the pine, and especially of the root of the tree. The specific gravity of ordinary tar is about 1·040. Peat yields a tar very similar to wood-tar. Coal yields, on distillation in closed vessels, even a larger number of products of distillation than are yielded by wood. In addition to numerous gaseous products, the liquid portions contain water and various forms of hydrocarbon, which collectively form the liquid known as *coal-naptha;* besides which there is a large quantity of a dark viscous matter known as *coal-tar*. The mixture of naptha and tar is described in this work under the title of GAS-TAR. For an account of the beautiful *Coal-tar Colors* or aniline dyes, see the articles DYE-STUFFS and PHENYL.

The distillation of coal-tar is conducted on an extensive scale as a separate branch of trade. From Miller's *Organic Chemistry* we extract the following remarks on the compounds present in this substance: 'Of the substances contained in coal-tar, some are basic, and some acid, but the principal portion consists of neutral or indifferent bodies. The basis include ammonia, aniline, picoline, quinoline, and pyridine. Among the acids, the acetic is present in small amount; but the most important is phenic acid, the carbolic acid of Runge. This chemist also mentions two other acids named *rosolic* and *brunolic* acids. The neutral substances contain several hydrocarbons, including benzol, tuluol, cumol, and cymol, which are among the liquid constituents; while naphthalin, anthracene, chrysene, and pyrene are amongst those which are solid at ordinary temperatures.' When either wood-tar or coal-tar is submitted to distillation, the solid brown or black residue left in the retort constitutes *pitch*.

Wood-tar, under the title of *Pix liquida*, is included in the Pharmacopœia, in which its characters are given as follow: 'Thick, viscid, brownish black, of a well-known peculiar aromatic odor. Water agitated with it acquires a pale-brown color, sharp empyreumatic taste, and acid reaction.' Tar was more used in medicine in former times than at present. Bishop Berkeley's commendatory essay on the use of tar-water, in diseases of the chest and kidneys, is well known to all literary students (see Chambers's *Book of Days*, vol. i. p. 108). Since his time the inhalation of tar-vapor has been highly recommended in cases of phthisis; and tar-capsules are still occasionally prescribed in cases of relaxed mucous membrane. In the present day, tar is, however, seldom used except as a local stimulant in chronic cutaneous diseases.

In modern commerce, there are two kinds of wood-tar known—that made in the north of Europe from the wood of *Pinus sylvestris*, and the North American, which is made from *Pinus rigida*, *P. tæda*, *P. Australis*, &c. The distillation is usually performed in a very rude manner: a funnel-shaped hole is dug in a bank, about 6 or 8 feet in diameter at the upper part, and not more than 18 inches at the lower. At the bottom of the hole is placed an iron pan, having a long spout or pipe, which is made to pass through the bank; the hole is then filled up with billets cut from the roots and branches of the pine-trees, which, after being kindled at the top, are covered over incompletely with turf. The wood is thus charred from above downwards; and the tar, mixed with various other products, flows off at the bottom through the spout into a receiver. A somewhat similar product is obtained in the distillation of coal for gas, and in the distillation of bones in forming animal charcoal. Formerly, the chief value of these materials was as a preservative coating for exposed wood-work, ships, sails, ropes, &c., in consequence of their very highly antiseptic properties. A better knowledge of their chemical history has, however, much increased their value. The imports of wood-tar into Great Britain exceed five millions of gallons annually; while the supply of coal-tar produced in the gas-works, charcoal-works, and bone-works of the United Kingdom cannot be estimated at much under that quantity.

TA'RA, or TARO (*Colocasia macrorhiza*), a plant of the natural order *Araceæ*, of the same genus with the Cocco (q. v.), or Eddoes, and cultivated for its roots, which are a principal article of food in the South Sea Islands. The roots are 12 to 16 inches long, and as much in girth. They are washed to take away their acridity, which is such as to cause excoriation of the mouth and palate. They are cooked in the same way as bread-fruit, the rind being first scraped off. A pleasant flour is made of tara. Many varieties are cultivated. The plant has no stalk; broad, heart-shaped leaves spring from the root; and the flour is produced in a spathe. The leaves are used as spinach.

TARA FERN (*Pteris esculenta*), a species of Brake (q. v.), the root (rhizome) of which was one of the principal articles of food of the New Zealanders, before the settlement of New Zealand by British colonists. This fern comes to perfection only in good soils, and there the plant is 10 feet high. Plants three years old furnish the best roots, which are about an inch in circumference. The root, being dug up, is cut in pieces about 9 inches long, and placed in stacks, carefully protected from rain; it is the better of being a year above ground. For use, it is steeped in water, dried in the sun, and then roasted. A large quantity of a very pleasant flour is obtained from it by beating on a stone.

TARANAKI, a provincial district of New Zealand, occupying the south-west corner of the north island; area, 2,137,000 acres, of which three-fourths are dense forest. The coast is lined with iron-sand. The soil and climate are good for rearing cattle, horses, and sheep. Pop. (1881) 14,858. The capital is New Plymouth, pop. (1881) 3310.

TA'RANTISM may be defined a leaping or dancing mania, originating in, or supposed to originate in, an animal poison. The name is supposed to be derived from the ground-spider, *Tarantula* (q. v.), which conveyed the poison into the human body by its bite. The gesticulations, contortions, and cries somewhat resembled those observed in St. Vitus's Dance, and other epidemic nervous diseases of the middle ages, with which tarantism was contemporaneous; but the affection differed from these in its origin, in the cachexia present, in the elegance of the movements of the victims, in their partiality for red colors, bright and luminous surfaces, their passion for music, and in their restoration depending upon the use of instrumental or vocal music as a remedy.

Although the sufferers were subjected to extraordinary treatment, such as being buried up to the neck in earth, the success of music was so universal and invariable, that a class of tunes is said to have been composed, called *Tarantella* or *Tarentella*, to be employed in the cure of the tarantati. The name may, however, have been given to the dance so called (with pipe and tambourine accompaniment), simply because popular in and near Taranto, and have passed to all musical compositions in the rapid triplet time of the dance. T. was most prevalent in Apulia, where the insects abound. Whatever share in the disorder the bite of the tarantula spider may have had, it is unquestionable that the sufferers were afflicted with some not then recognized nervous malady. The symptoms are plainly those of hypochondriacal and hysterical affections. Modern experiments have proved that the bite of the tarantula is in nowise more dangerous or remarkable in its effects than that of other spiders.—Hecker, *Epidemics of Middle Ages;* Madden, *Phantasmata;* Bergsoe, *Die Italienische Tarantel*.

TARA'NTO (anc. *Tarentum*), a town of Southern Italy, in the province of Lecce, is situated on a rocky islet, formerly an isthmus, between the Mare Piccolo (Little Sea), an extensive harbor on the east or landward side of the town, and the Mare Grande (Great Sea), or Gulf of Taranto, on the west. The natural channel between the two 'seas' has been spanned by a long bridge of seven arches, rendering the Mare Piccolo quite useless as a harbor, and forcing ships to anchor in the outer roads, which are much exposed to south and south-west winds. The principal buildings of T. are a cathedral dedicated to St. Cataldo, a native of Raphoe in Ireland, who was first Bishop of T.; a fine episcopal palace; a castle and fortifications erected by Charles V., and commanding both seas; and two hospitals. The streets are as narrow and dark as those of an oriental city. T. has manufactures of

velvets, linens, and cottons, but little commerce. The Mare Piccolo, however, is still famous (as of yore) for its immense abundance of shell-fish, and a considerable portion of the population (which in 1881 amounted to 33,942) derives its subsistence from the oyster and mussel fisheries.

Ancient Tarentum, however, was a far more famous and splendid city than its modern representative. Founded by a body of Spartan emigrants about 708 B.C., it grew and prospered for centuries in happy obscurity. Its territory was not perhaps very fertile, but its pasturage was of the finest, and its olive groves were unsurpassed. Yet it was not these things that ultimately made it the sovereign city of Magna Græcia; this rank it attained through the supreme excellence of its harbor (the Mare Piccolo), ample and secure beyond all the other harbors of Lower Italy. Gradually it became the chief emporium of the Græco-Italian trade, and long after all the rest of the colonial cities in Magna Græcia had fallen into decay, Tarentum was 'blooming alone' in undiminished prosperity. We may pass over its earlier history, noticing only the fact, that in the 4th c. B.C., it had for its *strategos*, or general (seven times), the philosopher and geometer Archytas, under whom it became the headquarters of the Pythagorean sect, and was honored with a visit from Plato, who was the guest of Archytas during his residence there. But while in the very acmé of its greatness, it provoked a quarrel with Rome (q. v.), 281 B.C., in which, though aided by the gallantry of Pyrrhus (q. v.), king of Epirus, it was utterly crushed, after a struggle of less than ten years; and though its natural advantages hindered it from sinking into such absolute insignificance as other cities of Magna Græcia, it was never after a place of great importance. Under the Empire, it was quite overshadowed by Brundusium on the Adriatic, but rose again during the Gothic wars, and passed into the hands of the Saracens and Greeks, from the latter of whom it was wrested by Robert Guiscard, the Norman, in 1063. Since then, it has shared the fortunes of the kingdom of Naples. Few relics of the classic Tarentum are extant, the chief being bits of an amphitheater, a circus, and traces of some of the temples.

TARA'NTULA (*Lycosa tarantula*), a species of spider, of a genus to which the name Wolf-spider is often given, a native of the south of Europe. It derives its name from the city of Taranto, in Italy, where it is very plentiful. It is one of the largest of European spiders, of a somewhat elongated shape, with rather long legs. It is one of those spiders which seek their prey by hunting. Its bite is much dreaded, and has been supposed to cause

Tarantula Spider (*Lycosa tarantula*).

the disease called *Tarantism* (q. v.).—Several species of spider nearly allied to the T. are found in different parts of the south of Europe. One of them (*Lycosa Narbonnensis*) frequents dry uncultivated grounds in the south of France, and makes a little pit in the ground, near the entrance of which it sits watching for prey. The prey is carried into the pit to be devoured. The female shows great affection for her young.

TARARE, a thriving and important manufacturing town of France, in the dep. of Rhone, stands at the foot of Mount Tarare, one of the highest summits of the Beaujolais range, 21 miles north-west of Lyon. Formerly unimportant, it is now a rich and flourishing town, the inhabitants of which are engaged in the manufacture of muslins, cloth, silk, and merino fabrics, and in embroidering and bleaching. The muslins of T. are famous for their fineness. See TARLATAN. Pop. (1876) 13,563.

TARASCON, a town of France, in the dep. of Bouches-du-Rhone, 13 miles south-west of Avignon by railway. The church of St. Martha dates from the year 1187, and is so called after Martha, the sister of Lazarus, and the patron saint of the town. Woollen and silk fabrics, and brandy and vinegar, are manufactured. Pop. (1876) 7777.

TARA'XACUM, or Dandelion (q. v.) Root, is employed to a considerable extent in medicine. The roots should be gathered in August and September, when the juice is most abundant. There is no very satisfactory analysis of this juice, but it is said to contain mannite, resin, sugar, gum, caoutchouc, and a crystallizable matter termed *taraxicine*, on which its active properties probably depend. This medicine may be prescribed with advantage in the form of extract, decoction, or juice in chronic diseases of the liver, and in certain forms of dyspepsia and skin-disease which are accompanied by derangement of the biliary organs. In very large doses, it has a diuretic and slightly aperient action.

TARAZO'NA, a town of Spain, in the province of Zaragoza, 52 miles west-north-west of the city of that name, on the Queyles, a tributary of the Ebro. It stands on a wind-blown plain, exposed to bleak winds from the Sierra de Moncayo on the south, and from the Pyrenees on the north. It is the see of a bishop; and contains a cathedral with a slender brick spire and rich interior, a bishop's palace, and a Moorish *Alcazar*. Pop. upwards of 8000, mainly engaged in agriculture.

T. is the ancient *Turiaso;* and here a few Roman troops routed a Celtiberian army. It became a municipium under the Romans; and under the Goths, by whom it was fostered, it became famous for its steel.

TARBAGATAI', a frontier town of Chinese Turkestan, 170 miles east of the eastern extremity of Lake Balkash, in lat. 46° 44′ N., long. 82° 28′ E. It stands at the foot of the mountains of the same name, in a plain watered by the Imil, and with extensive meadows and pasture-grounds in the vicinity. The inhabitants consist of 3000 exiled Chinese, 1000 of a Chinese garrison, and a number of Mongolian merchants. The trade with Russia is important.

TARBES, a town in the south of France, capital of the dep. of Hautes-Pyrénées, stands on the left bank of the Adour, 23 miles east-south-east of Pau. It is a station on the *Chemin de fer du Midi*, and the center of communication with all parts of the Pyrenees, the lofty line of which bounds the prospect on the south. The modern cathedral is the principal and indeed the only notable building. There is here a *haras*, or government stud, for the improvement of the breed of horses. T. is the seat of an active general trade. Pop. (1876) 11,080.

T. dates from the time of the Romans, and its bishopric was founded in the year 420.

TARDIGRADA. See SLOTH.

TARE (*Ervum*), a genus of plants of the natural order *Leguminosæ*, sub-order *Papilionaceæ*, distinguished from *Vicia* (see VETCH), to which it is nearly allied, by a capitate stigma, downy all over. It contains only a few species of weak climbing plants, natives of the temperate parts of the Eastern Hemisphere. One of these is the LENTIL (q. v.).—Two (*E. hirsutum* and *E. tetraspermum*), generally known by the name of TARE, are common in cornfields and hedges in Britain. They have very small flowers and pods; the leaves are pinnate and the leaflets small. They afford nourishing food for cattle; but the quantity is so small that they are not worthy of cultivation, and are chiefly known as a nuisance in cornfields. A species of T. (*E. sativum*), with an upright branching habit, is cultivated in some parts of Europe for its herbage, which is used for feeding cattle. The bulk of herbage is small, but its nutritious character is thought to compensate for this. The leaves have from 8 to 14 pair of leaflets. The plant thrives well in poor sandy soils.—It is not supposed that the *Tare* of the New Testament has any affinity to these plants: it is doubtful what it is, but it appears not improbable that it is the DARNEL (q. v.).

TARE AND TRET, certain deductions usually made from the gross weight of goods. *Tare* is the weight of the box, cask, bag, or wrapping in which the goods are contained; and the amount is obtained either by weighing the empty package itself, by taking an average of a few similar packages of equal size, or by mutually agreeing upon a certain proportion of the gross weight. The remainder, after deducting the tare, is the *net weight*. Another deduction at the rate of 4 lbs. for every 104 lbs., or $\frac{1}{26}$th of the net weight, is then made, as an allowance for waste through dust, &c., and is called *tret*. Some other allowances of minute magnitude as draft, cloff, &c., are occasionally made after tret, but they are falling into disuse.

TA'RGET (root uncertain, but the word, in some form, found in all European languages), in its modern sense, is the mark for aiming at in practising with the cannon, rifle, or bow and arrow. In its more ancient meaning, a target or targe was a shield, circular in form, cut out of ox-hide, mounted on light but strong wood, and strengthened by bosses, spikes, &c. Of modern targets, the simplest is that used for Archery (q. v.). With regard to rifle targets, the spread of the Volunteer movement and the numerous rifle-matches have caused ranges to be constructed over the whole country. The necessities are: a butt, artificially constructed or cut in the face of a hill, to prevent wide balls from scattering—a marker's shot-proof cell, near the targets—and a range of such length as can be procured. The sizes of targets used by the British army are as follows: for firing up to 300 yards, the target is 6 feet high by 4 feet broad, with a circular bull's-eye 1 foot in diameter, and a center of 3 feet. Up to 600 yards, the target is 6 feet square; bull's-eye, 2 feet diameter; center, 4 feet (see fig. 3).

Up to 800 yards, the target is 6 feet by 8; bull's-eye, 3 feet in diameter; and center, 5 feet (see fig. 4).

The marker signals the 'hits' from his box, denoting a bull's-eye by a red-and-white flag, a center by a blue flag, and an outer by a white flag. If he show a red flag, it is to cease firing while he inspects the target. In scoring, the outer counts 2; center, 3; and bull's-eye, 4. A red flag should fly on the butt during the whole time of practice, to warn passers-by to keep off the range. The targets used by the National Rifle Association at Wimbledon are not the same as those used by the army. According to the Wimbledon regulations of 1876, the target for the distance of 200 yards had a circle of 40 inches diameter, divided into the circular bull's eye 8 inches in diameter, a center of 16 inches diameter, an 'inner' of 28 inches, the rest of the 40 inches being accounted 'outer.' On the target for 500 and 600 yards, the circle of 70 inches falls into a bull's-eye of 22 inches diameter, center 38 inches, inner 54 inches, and the rest outer.

Fig 1.—Archery Target.

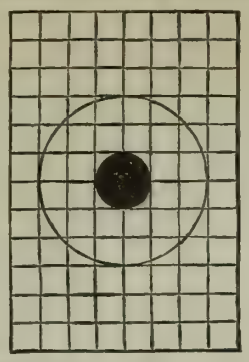

Fig. 2.—Target for distances up to 300 yards.

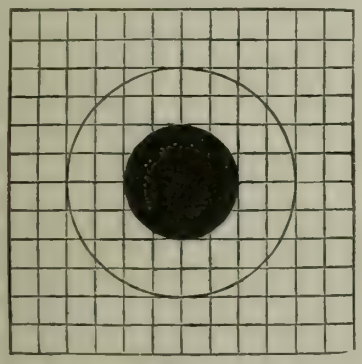

Fig. 3.—Target for distances up to 600 yards.

The rectangular frame for 800, 900, and 1000 yards distance had a circular bull's-eye of 3 feet in diameter, a centre 4 feet 6 inches, a square inner of 6 feet, the remainder of the target counting as outer. Of the ordinary Wimbledon targets for 1880 (as in 1878), that for 200 yards distance is divided into a bull's-eye 8 inches in diameter; 'inner,' 1 foot; 'magpie,' 2 feet; and outer, the remainder of the target, 4 feet square. At 500 and 600 yards, the bull's-eye is 2 feet in diameter; the inner, 3 feet; the magpie, 4 feet; and outer, the rest of the target of 6 feet square. At 800, 900, and 1000 yards, the bull's-eye is 3 feet diameter; inner, 4½ feet; magpie, 6 feet square; and outer, the rest of the target of 12 feet by 6 feet.

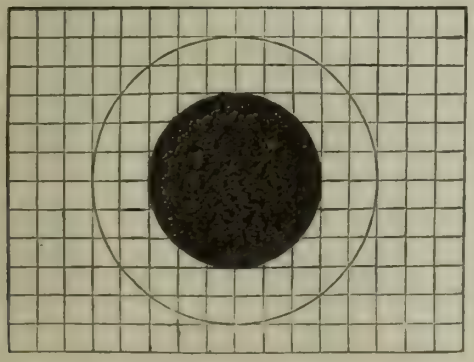

Fig. 4.—Target for distances up to 900 yards.

Previous to the inaugurating of the Wimbledon meeting in 1860, all targets were circular, and made of iron. From that year till 1873 inclusive, they were square iron plates; but in 1874, targets of canvas stretched on an iron frame were introduced. The superiority as marksmen displayed in the Transvaal war by the Boers suggested the introduction into military training of practice at objects moving at various rates of speed and at a greater or less distance. A 'running-man target' has been devised, which consists of a mill-board figure running on wires, worked by the marker in the butt.

TARGOWI'TZ, or TARGOWICZA, in Russia, a small town in the government of Kiev, was the scene (May 1792) of a plot by five Polish nobles who were adverse to the constitution of 3d May 1791 (see POLAND). They were incited to this by Catharine II., and only escaped death by precipitate flight to Russia, where they were munificently rewarded.

TA'RGUM (Chaldee, from *tirgem*, a word of uncertain origin, designating to translate, explain), the general term for the Aramaic Versions of the Old Testament, which became necessary when, after, and perhaps during the Babylonian Exile, Hebrew began to die out as the popular language, and was supplanted by 'Chaldee,' an idiom, or rather a family of idioms, on which we have spoken under SHEMITIC LANGUAGES.

The origin of the Targum itself is shrouded in mystery. The first signs of it—as an already fixed institution—have been found by some in the book of Nehemiah, and according to tradition, Ezra and his coadjutors were its original founders. However this be, there can be no doubt that its beginnings belong to a comparatively early period. The Mishna (q. v.) contains a number of strict injunctions respecting it, and also respecting a certain guild of Meturgemans (whence dragoman) or interpreters, who had sprung up as professional followers of those learned men who, at a previous period, had volunteered their services in the translation and paraphrastic interpretation, both activities, as we said, implied by the term.

At first, and indeed for many centuries, the Targum was not committed to writing, for the same reason that the 'Oral Law' itself was not at first intended ever to become fixed as a code for all times. In the course of time, however, both had to yield to circumstances, and their being written down, was considered preferable to their being utterly forgotten, of which there was no small danger. Yet a small portion only of the immense mass of oral Targums that must have been produced, has survived. All that is now extant are three distinct Targums on the Pentateuch, a Targum on the Prophets, Targums on the Hagiographa, viz., on Psalms, Job, Proverbs, the five 'Megilloth' (Song of Songs, Ruth, Lamentations, Esther, Ecclesiastes), two Targums on Esther, one on Chronicles, one on Daniel, and one on the apocryphal pieces of Esther. The most important of the three Pentateuch Targums is the one named after Onkelos (q. v.) probably a corruption of Akylas, whose Greek version had become so popular that this Chaldee version was honored with being called after it. In its present shape, this translation dates probably from the end of the 3d or beginning of the 4th c. A.D., although snatches of it were collected and written down more than a hundred years earlier. We have spoken of its language and its general character already under ONKELOS, and may here briefly state that it is composed in an Aramaic closely resembling that of Daniel, and that it is as excellent a translation 'for the people,' which it meant to be, as can well be conceived. Occasionally, when the subject imperatively demands it, it introduces some paraphrastic by-work, and it only deviates from the text where the divine dignity would have appeared to suffer in the eyes of the multitude by a literal interpretation. Its value for exegetical purposes is no less great than it would be for linguistic and antiquarian purposes, were it more explored with that view than has been the case as yet.

The two other Targums on the Pentateuch, hitherto known as Targum Jonathan ben Uzziel, and Targum Jerushalmi, are merely recensions of one and the same version—the name of the first recension being merely a perpetuated error of a single scribe—which owes its origin to Palestine or Syria (Onkelos being of Babylonian origin), and cannot well have been redacted before the 7th c. A.D. There is no doubt that originally this 'Jerusalem Targum' embraced the whole of the Old Testament, as did the Babylonian; but nothing has survived beyond these two recensions of the Pentateuch, the first complete, the second in a fragmentary condition: the former probably intended as an emendation of Onkelos, chiefly in the direction of homiletic paraphrase and legendary lore, and the latter as a further emended emendation of single portions. As a version, this Targum is of small importance; but it is invaluable as a storehouse of allegories, parables, sagas, and the like popular poetry of its time. Its language and grammar are exceedingly corrupt; it abounds, moreover, with foreign—Greek, Latin, Persian, and Arabic—terms; and its general use lies more in the direction of Jewish literature itself, as well as of archæology and antiquities of the early Chris-

tian centuries, than in that of a direct interpretation of the Bible text itself. The Targum on the Prophets is generally and erroneously ascribed to Jonathan ben Uzziel, an eminent master of the law at the time of Hillel the Elder; the fact being that, except one spurious Talmudical passage, in which mention is made of his having translated the Prophets, this Targum is everywhere else, from the Talmud down to the authorities of the 10th c. A.D., ascribed to one R. Joseph, president of a Babylonian academy in the 4th century. And it would indeed seem as if this statement were completely in accordance with the real facts—if not the writing, but the collection and final redaction of this Targum is ascribed to him. Respecting the nature of this version, it may be said that, while being tolerably literal in the first—historical—books, it gradually becomes a mere framework of Midrash (q. v.) or Haggada, which it introduces at every turn and at great lengths. It further contains historical bits, disguised, or rather typified, and some lyrical pieces of rare poetical value. In language and general manner, it resembles Onkelos, with which it is of one growth, place, and date, and of which it forms only a kind of continuation.

To the same Joseph 'the Blind' to whom the redaction of the foregoing Targum is probably due, is further ascribed a Targum on the Hagiographa. But between him and the Hagiographical Targums lie, at the least, 600 years; their date being approximately given as about 1000 A.D. Certain distinctions between the different books must further be made. The Targums on Psalms, Job, and Proverbs were probably contemporaneous compositions due to Syria. The two former are made more paraphrastic than the last, which resembles closely the Syriac version. The paraphrase on the five 'Megilloth'—a very late production indeed—is principally a collection of more or less poetical fancies, traditions, and legends, to which the single verse in hand merely seems to furnish the key-note. There is, we need not add, but very little to be found in them of what originally must have formed the Targum on these books; nor is there the slightest hint to be fouud as to who was the real author or editor of their present form. That it was one man's work, is probable enough, from a certain unity of design and style noticeable in all of them. Their dialect lies somewhat between the East and West Aramaic. The Targum on the Book of Chronicles—almost unknown until the 17th c.—also belongs to a late period, and was probably composed in Palestine. There are some useful philological, historical, and chiefly geographical hints to be gleaned from it, but nothing more; least of all can it be used exegetically. A Persian version of a Targum on Daniel (unedited) is all that has been discovered on that book as yet. It was probably composed in the 12th c., the influence of the early Crusades being plainly visible in it. On the paraphase of the apocryphal pieces of Esther, we shall not dwell here, any more than on the scanty fragments of a 'Palestinian Targum' that are found either interspersed in the general (Babylonian) Targum, or as independent pieces. It seems probable that more of this Palestinian version will come to light some day, as authorities of a few centuries back still quote from it rather largely. At present, however, their quotations are nearly all that remains.

Very little—we might say, next to nothing—has been done as yet to utilize this most important branch of Aramaic literature; in fact, not even an attempt at anything like a critical edition has been made, although it would be difficult to find a more corrupt text than that offered by the MSS. and single printed portions. Some parts have been done into Latin, English, German, &c. The ed. pr. of Onkelos is dated Bologna, 1482; that of the Targum on the Prophets, Leiria, 1494.

TARI'FA, a seaport town of Spain, 20 miles south-west of Gibraltar. It is the most southern town of Europe, is surrounded by tower-embattled walls, and communicates by a causeway with a small island, on which stand a fortress and light-house. The town is the most thoroughly Moorish in Andalusia; it is quadrangular in shape, and its streets are narrow and dark. Tunny and anchovy fisheries are actively carried on. Pop. (1877) 12,234.

T., the Carthaginian *Josa*, and the Roman *Julia Traducta*, received its present name from the Moors, who are said to have called it after Tarif (= Tarik? Ibn Malik, who landed there to reconnoitre previous to the conquest of the country. See MUZA; RODERIC. It was successfully defended in 1811 by 2500 troops (mostly British) against a French force of 10,000 men, under Victor and Laval.

TA'RIFF (from *Tarifa* (q. v.), where, during the rule of the Moors in Spain, duties were collected), a table or catalogue, generally drawn up in alphabetical order, of the duties, drawbacks, bounties, &c., charged or allowed on different kinds of merchandise, as settled by authority, or agreed to between different states. The principles of the tariffs of different countries depend on their respective commercial policy, and on the fluctuating interests and wants of the community. According to the presently existing British tariff, only about 20 kinds of merchandise are subject to an import duty, and none to an export duty.

TARIM RIVER. See TURKESTAN, EASTERN.

TA'RLATAN, a thin gauze-like fabric of cotton, used for ladies' ball dresses, &c. It is usually dyed or printed in colors. Tarare, in France, is the chief center of this manufacture, whence it is largely exported. Switzerland alone competes with France in the production of tarlatan, but those of the latter country far surpass the former in fineness.

TARN, a dep. in the south of France, bounded on the N. by the deps. of Aveyron and Tarn-et-Garonne, receives its name from the river Tarn. Area 2216 sq. m.; pop. (1881) 359,223. The surface is in general elevated, and in the south and south-east are the Montagnes Noires and the Monts de l'Espinous, branches of the Cévennes. The rock of Montalet, the principal summit, is 4430 feet high. Wooded mountains, vine-clad hills, beautiful valleys, and fertile or grass-producing tracts, are the principal features of the landscape. The chief river is the Tarn, an affluent of the Garonne (q. v.), and which has a westward course of 200 miles. A fifth part of the surface is covered with forests, chiefly of oak and beech. The dep. is for the most part agricultural, and the most improved methods are in use. Eleven million gallons of wine are made in average years. T. is divided into four arrondissements: Albi, Castres, Gaillac, and Lavaur. Albi is the capital.

TARN-ET-GARONNE, a small dep. in the south of France, bounded on the S.-E. by the dep. of Tarn. Area, 1435 sq. m.; pop. (1881) 217,056. The principal river is the Garonne, which flows north-west, and its affluents, the Tarn and Aveyron. The surface is marked by plateaux, about 1000 feet in average altitude; the highest hills do not rise above 1600 feet. The climate is beautiful, healthy, and temperate. Cereals are raised in great quantities. Of wine, 11,000,000 gallons are produced. The dep. is divided into the three arrondissements of Montauban, Castelsarrasin, and Moissac. Montauban is the capital.

TARNO'POL, a town of Austria, in Galicia, charmingly situated on the left bank of the Sered, 80 miles east-south-east of Lemberg. Agriculture employs the great mass of the inhabitants, and the horse-market held here periodically is the most important in Galicia. Horse-races also take place. Pop. (1880) 25,819.

TA'RNOW, a town of Austrian Galicia, near the right bank of the Dunajec, a navigable tributary of the Vistula, and 49 miles east of Cracow by the Vienna and Lemberg Railway. It is the seat of a Catholic bishop, contains a theological college, and a beautiful cathedral, in which are numerous monuments of marble, surmounted by statues, enriched with *bassi rilievi*, and rising to from 60 to 70 feet in height. Several industries are actively carried on, and there is a good general trade. Pop. (including suburbs) (1880) 24,627.

TARPAU'LIN, a large sheet of the coarsest kind of linen or hempen cloth, saturated with tar to render it waterproof. It is used for covering loaded wagons, the hatchways of ships, and similar things, as a temporary protection from wet.

TARPEI'AN ROCK (Lat. *Rupes Tarpeia*, or *Mons Tarpeius*), the name originally applied to the whole of the Capitoline Hill (see CAPITOL), but latterly confined to a portion of the southern part of the hill, the following being the legend commonly related in connection with it. In the time of Romulus, Tarpeia (a vestal virgin), the daughter of Sp. Tarpeius, governor of the Roman citadel on the Capitoline, covetous of the golden ornaments on the Sabine soldiery, and tempted by their offer to give her what they wore on their left arms, opened a gate of the fortress to the Sabine king, Titus Tatius, who had come to revenge the rape of the Sabine women. 'Keeping their promise to the ear,' the Sabines crushed Tarpeia to death beneath their shields, and she was buried in the part of the hill which bears her name. Subsequently, it was not unusual for persons condemned on the charge of aspiring to restore the monarchy, or of treason to the state generally, to be hurled from the T. R.—e. g., the famous Manlius, the savior of the Capitol during the invasion of the Gauls.

TARQUI'NIUS, the family name of two kings of Rome, with whose history, or rather with the legends regarding whom, the fortunes of the city are closely interwoven. The story goes that Demaratus, a Corinthian noble, emigrated from Greece, and settled at Tarquinii, in Etruria, where he married an Etruscan wife, by whom he had two sons, Aruns and Lucumo. Aruns died during his father's lifetime, but Lucumo married into one of the noblest Etruscan families. His wife, named Tanaquil, was a bold, ambitious, and wise woman. By her advice, Lucumo resolved to go to Rome. He set out, accompanied by a large train of followers, and as he approached the Janiculum, an eagle swooped down, and snatching off his cap, carried it up to a great height, then descending, placed it on his head again. Tanaquil, who was deeply skilled in the science of augury, prophesied from this omen the

highest honors for her husband, who was hospitably received at Rome, and soon after admitted to the rights of citizenship, whereupon he took the name of L. Tarquinius, or, according to Livy, L. Tarquinius Priscus. The Roman monarch, Ancus Marcius, appointed him guardian of his children; and on the death of the former, the senate and the citizens unanimously elected him to the vacant throne. His reign was a glorious one. Against the Latins, Sabines, and (according to Dionysius) the Etruscans, he waged successful war, forcing the whole of the twelve sovereign cities of Etruria to recognize his supremacy, and do him homage. But the works that he executed at home are even more renowned than his exploits abroad. To L. Tarquinius Priscus (*Priscus* is commonly translated the 'Elder;' but Niebuhr objects to this translation as involving an anachronism, and notices the fact that *Priscus* is a common cognomen among the Romans) are ascribed the construction of the magnificent *Cloacæ*, or sewers (see, however, CLOACA MAXIMA), which remain uninjured to this day; the laying out of the Circus Maximus and the Forum; the institution of the great or Roman games; and (some say) the building of the Capitoline temple (see CAPITOL.). The legend also represents him as effecting certain political and sacerdotal changes. See ROME.

T. was assassinated after a reign of 38 years, at the instigation of the sons of Ancus Marcius, who considered themselves as best entitled to the throne, and dreaded lest he should use his influence to get his favorite and son in-law, Servius Tullius, chosen as his successor. But their crime did not avail them, for, through the dexterity of Tanaquil, Servius was elected to the vacant throne, and signalized himself not only by his military exploits, but also by great organic changes in the Roman constitution (see article ROME for an account of the 'Servian Reform'). T. left two sons, L. Tarquinius Superbus and Aruns, both of whom married daughters of Servius Tullius; and two daughters, one of whom married Servius Tullius himself and the other M. Brutus, by whom she became mother of L. Brutus, first consul of the Roman Republic.

L. TARQUINIUS SUPERBUS, son of the preceding, having murdered his father-in-law, Servius Tullius, at the instigation of his wife, is represented in the legend as audaciously usurping the vacant throne; but as the whole drift of his legislative policy was to abolish the reforms of Servius, there can be little doubt that the real significance of this part of his career lies in the fact, that it indicates a successful reaction, on the side of the patricians, against the more liberal and progressive policy of the preceding age. That the younger T., at least, is a historical character seems to be pretty generally allowed. The incidents of his career are so numerous and coherent, and the impress of his name and character is so deeply stamped on the national memory, that he cannot be regarded as a wholly imaginary personage. Analyse the story how we may, there will always remain a residuum of insoluble fact, not essentially at variance with the character of the tragic tradition. As far as we can gather from the ancient annals, the usurpation of T. was probably achieved by the help of an enterprising section of the nobles, who clung tenaciously to their privileges, and could not endure the constitutional recognition of the *plebs*.

It does not appear that the whole of the senators connived at or even approved of T.'s procedure. We are expressly told that he drove numbers of those whom he mistrusted into exile; in other words, he persecuted and banished the adherents of the Servian policy of conciliation. Like a Turkish tyrant, he surrounded himself with a body-guard—another indication of the original insecurity of his position, and strengthened himself by foreign alliance, marrying his daughter to Octavius Mamilius, Prince of Tusculum. By means of subtle and unscrupulous intrigues, he obtained or consolidated the Roman hegemony in Latium; offered sacrifice in the name of all the Latins at the Alban Mount; fused the contingents of the latter with the Roman legion; put to death as traitors such of their chiefs as opposed him (e. g., Turnus Herdonius); and, at the head of the combined forces, penetrated into the Volscian marshes, and subdued the natives. On his return, he completed the building of the Capitol, which the Elder T. had begun, and deposited in the vaults the Sibylline books he had curiously acquired. See SIBYL. He next conquered the town of Gabii (where many of the banished nobles had found shelter), through an elaborate stratagem, in which his son Sextus played the principal part. But his lavish expenditure both in war and peace necessitated the imposition of heavy taxes, and murmurs of discontent were heard among the people. The patience both of plebs and patricians was beginning to give way. Coincident with this state of things, a fearful omen was beheld: from the altar in the royal palace crept forth a serpent, and devoured the entrails of the victim.

T. sent two of his sons, Titus and Aruns, to Delphi to consult the oracle. They were accompanied by their cousin, L. Junius Brutus (q. v.), who had long feigned himself a fool in order to save his life, for T. had killed his father and brother in order to possess himself of their great wealth. On their return, they found that the king had opened war upon the Rutuli, and was besieging Ardea, whereupon they joined the Roman camp. Here occurred, between Sextus and Callatinus, the famous dispute about the virtues of their respective wives, which led to the rape of Lucretia. The details of this legend are so familiar that it is unnecessary to recount them. Suffice it to say that it roused such a storm of indignation, that the people of Collatia (where the shameful deed was done) rose in arms, and renounced their allegience to Tarquinius. Brutus carried the news to Rome, and the senate, fired with a righteous anger, deposed the tyrant; finally, the army before Ardea also revolted. T. and his sons were obliged to flee, and an aristocratic republic was constituted at Rome. Three different attempts were made to restore T. by force: first, by his own Etruscan kinsmen of Tarquinii; second, by Lars Porsena (q. v.) of Clusium; and third, by his son-in-law, Octavius Mamilius, 'prince of the Latian name,' all of which, according to the legend, failed; and at length T., utterly baffled and beaten, retired to Cumæ, where he died, a wretched and childless old man, for all his sons had met death before him.

TA'RRAGON. See ARTEMISIA.

TARRAGO'NA, a seaport of Spain, chief city of the modern province of the same name, stands on the Mediterranean shore, at the mouth of the Francoli, 60 miles west of Barcelona. It consists of two portions—the upper (the ancient) and the lower (the modern) towns. The former stands on a hill 720 feet high, and is girdled with ramparts. The lower town, completely separated from the higher by a line of works, is regular and open, and is defended by two forts. The beautiful cathedral, in Gothic and Norman, and which dates from the middle of the 12th c., is the principal edifice. There is an interesting antiquarian museum, rearranged in 1868. Brandy-distilling and the manufactory of wines and olive oil are the chief industries. The harbor is pretty good. Pop. (1877) 23,046.

T., called by the Romans *Tarraco*, was founded by the Phœnicians (who called it *Tarchon*, citadel), and afterwards became the capital of the Roman province of Tarraconensis. Among the Roman antiquities are the remains of an amphitheater, which has been used as a quarry; a magnificent aqueduct, 96 feet high, and 700 feet long—still in use—and near the town the Tower of the Scipios, much decayed. T. was taken and cruelly sacked, in June 1813, by the French under Suchet.

TA'RRYTOWN, a village of New York, U. S., on the east bank of the Hudson River, 27 miles north of New York city. It is beautifully situated on a lake-like expansion of the river, called the Tappanzee, surrounded with fine scenery, and filled with elegant residences. It has 6 churches and 4 academies, and is noted as the scene of the capture of Major André. Pop. 3500.

TA'RSHISH, probably the same as *Tartessus*, a city and emporium of the Phœnicians in Spain, somewhere near the mouth of the Guadalquivir. It is frequently mentioned in Scripture, notably so in connection with the prophet Jonah, who took ship for T. when he sought to 'flee from the presence of the Lord.'

TA'RSIA-WORK, a beautiful kind of marquetry made in Italy. It is produced by inlaying pieces of colored wood so as to represent figures and landscapes. That of Sorrento is very celebrated; and lately, many fine pieces of this work have been made in Perugia. It is usually applied to the decoration of cabinet-work.

TA'RSUS, anciently the chief city of Cilicia, and one of the most important in all Asia Minor, situated on both sides of the navigable river Cydnus, in the midst of a beautiful and productive plain, and about 18 miles from the sea. It was a great emporium for the traffic carried on between Syria, Egypt, and the central region of Asia Minor. In the time of the Romans, two great roads led from T., one north across the Taurus by the 'Cilician Gates,' and the other east to Antioch by the 'Amanian' and 'Syrian Gates.' T., judging from its name, was probably of Assyrian origin; but the first historical mention of it occurs in the *Anabasis* of Xenophon, where it figures as a wealthy and populous city, ruled by a prince tributary to Persia. In the time of Alexander the Great, it was governed by a Persian satrap; it next passed under the dominion of the Seleucidæ, and finally became the capital of the Roman province of Cilicia. At T., Antony received Cleopatra, when she sailed up the Cydnus, with magnificent luxury, disguised as Aphrodite. Under the early Roman emperors, T. was as renowned for its culture as for its commerce, Strabo placing it, in respect to its zeal for learning, above even Athens and Alexandria. It was the birthplace of the Apostle Paul, who received the greater part of his education here; and here the Emperor Julian was buried. Gradually during the confusions that accompanied the decline of the Roman and Byzantine power, it fell into comparative decay; but even yet, it is—under the name of *Tarso* or *Tersus*—the most considerable place in the south-east of Asia Minor, has a pop. of 30,000 (in winter); and exports corn, cotton, wool, copper, gall-nuts, wax, goats' hair, skins, hides, &c.

TA'RTAN, or PLAID, a pattern woven in cloth, in which bands of different colors are woven or printed side by side, both the warp and weft way of the material, thus giving the well-known checkered pattern. This is probably the oldest pattern ever woven; at all events, the so-called shepherd's plaid of Scotland is known to have a very remote antiquity amongst the eastern nations of the world. The plaid pattern admits of a very great variety of modifications, by the introduction of different colors, and by varying the amount of each color employed. These colored plaids were in great favor in the Highlands of Scotland, where each clan wore a particular kind as its distinctive dress.

TA'RTAR, a mixture of bitartrate of potash and tartrate of lime (see TARTARIC ACID), is a deposit formed from wine, and known in its crude form as Argol (q. v.). About 900 tons annually of this substance are imported into Great Britain, from the chief wine-producing countries of Europe and the Cape of Good Hope.

The word *Tartar*, which gives the name to tartaric acid, is derived from the Greek *Tartaros*, hell. 'It is called *Tartar*,' says Paracelsus, 'because it produces oil, water, tincture, and salt, which burn the patient as Tartarus does.'

TARTAR, CREAM OF. See TARTARIC ACID.

TARTAR, FOLIATED EARTH OF, an old name for acetate of potash, in consequence of the foliated satiny masses in which that salt occurs.

TARTAR OF THE TEETH is a deposit of salts of lime and organic matter from the saliva, and usually occurs most abundantly on the inferior incisors. If it is suffered to accumulate, it causes inflammation and absorption of the gum, and gradual loosening of the teeth. The accumulating of this substance may usually be prevented if due attention is paid to the cleaning of the teeth. 'The teeth,' says Dr. Druitt, 'should be cleaned at least twice a day with a soft tooth-powder (precipitated chalk is best) and a little soap. The hairs of the tooth-brush should be soft, and not too closely set, so that they may penetrate the better into the interstices of the teeth.' When the tartar has accumulated to any extent, it must be removed by the *scaling instruments* of the dentist.

TARTAR, SOLUBLE, a term applied by some chemists to neutral tartrate of potash, and by others to borotartaric acid. See TARTARIC ACID.

TARTA'RIC ACID. Ordinary tartaric acid, $C_8H_4O_{10},2HO$, is usually seen in the form of colorless, transparent, oblique, rhombic prisms, which are not affected by the action of the air, have an agreeable acid taste, and are soluble in water and alcohol. The crystals when gently warmed become strongly electric, the opposite sides of the crystals exhibiting the opposite forms of electricity. On heating tartaric acid to about 340°, it fuses; and at a slightly higher temperature it becomes successively changed, without losing weight, into two metameric acids, *metatartaric* and *isotartaric* acids, the former of which is bibasic and the latter monobasic. At about 374°, two atoms of the acid lose one equivalent of water, and *tartralic acid*, $C_{16}H_6O_{20},3HO$, is formed. If the same temperature be maintained a little longer, half the basic water is expelled, and *tartrelic acid*, $C_{16}H_6O_{20},2HO$, is formed; and finally, all the basic water is driven off, and *anhydrous tartaric acid*, or *tartaric anhydride*, $C_8H_4O_{10}$ (or $C_{16}H_8O_{20}$), remains in the form of a white porous mass insoluble in water, alcohol, or ether. If, however, it be allowed to remain long moist, it gradually becomes converted into crystallized tartaric acid. Finally, on distilling tartaric acid in a retort at a temperature of 400° and upwards, it is decomposed into certain gases and empyreumatic oily matters, water, and acetic, pyruvic (or pyroracemic), and pyrotartaric acids.

Oxidizing agents, such as peroxide of lead or nitric acid, readily act upon tartaric acid, and convert it into formic and carbonic acids; and when fused with caustic potash, it splits up into acetic and oxalic acids. It is one of the strongest of the organic acids.

This acid occurs abundantly in the vegetable kingdom both in the free and combined state. It is found as a free acid in tamarinds, grapes, the pine-apple, &c.; and in combination with potash and lime in tamarinds, grapes, mulberries, and the unripe berries of mountain-ash, and in small quantity in the juice of many other vegetables. It is, however, from Argol (q. v.), a product of the fermentation of grape-juice, that the tartaric acid of commerce is obtained. The details of the process may be briefly described as follows: Argol, or crude bitartrate of potash, is dissolved in boiling water, and chalk is added as long as effervescence occurs. An insoluble tartrate of lime is precipitated, and tartrate of potash remains in solution. This tartrate of potash is converted, by the addition of chloride of calcium, into insoluble tartrate of lime and soluble chloride of potassium. The tartrate of lime obtained by these two operations, if treated with sulphuric acid, readily yields free tartaric acid in solution, with sulphate of lime as a precipitate. The filtered liquid, when cooled and evaporated, yields tartaric acid in crystals.

Tartaric acid is used in large quantity by calico-printers and dyers for the removal of certain mordants, and is much employed in medicine in the preparation of effervescing draughts and for other purposes.

Tartaric acid being bibasic, can form both acid and normal (or neutral) salts, according to the two general formulæ, $MO,HO,\overline{T}$, and $2MO,\overline{T}$, when M signifies any metal, and $\overline{T}$ is used as a symbol for anhydrous tartaric acid, $C_8H_4O_{10}$. The normal salts may contain (1) two similar or (2) different protoxides, or (3) a protoxide and a sesquioxide, or (4) a protoxide and a teroxide; as, for example—(1) Tartrate of potash, $2KO,\overline{T}$; (2) Tartrate of potash and soda, or Rochelle salt, $KO,NaO,\overline{T}$; (3) Tartrate of potash and iron, $KO,Fe_2O_3,\overline{T}$; (4) Tartrate of potash and antimony, or tartar emetic, $KO,SbO_3,\overline{T} + Aq$.

The tartrates are for the most part formed by partially or entirely saturating the free acid with an oxide or carbonate, or in the case of neutral tartrates containing two oxides, by saturating a solution of the bitartrate of one oxide with the other oxide. The most important tartrates are the following:

Tartrate of potash, $2KO,\overline{T}$, a soluble salt, which crystallizes with difficulty, and is formed in preparing tartaric acid from *bitartrate of potash*, $KO,HO,\overline{T}$. This salt is prepared from agol by extraction with boiling water, which dissolves about one-sixth of its weight. As it is much more insoluble in cold water, of which it requires 240 parts, it crystallizes readily as the hot solution cools. The snowy white rhombic prisms which are thus deposited constitute *cream of tartar*. When heated to redness in a covered crucible, a charred mass, consisting of carbonate of potash and charcoal in a fine powder, remains, and is used in the laboratory for reducing operations under the title of *black flux;* and if cream of tartar is deflagrated with twice its weight of nitre, *white flux*, also a reducing agent, consisting solely of carbonate of potash, is obtained. *Tartrate of potash and soda* has been already described in the article ROCHELLE SALT. *Tartrate of potash and iron*, or *Ferrum tartaratum*, $KO,Fe_2O_3,\overline{T} + Aq$, and *Tartrate of ammonia and iron*, or *Ammonio-tartrate of iron*, $H_4NO,Fe_2O_3,\overline{T} + 4Aq$, although the latter is not included in the Pharmacopœia, are excellent medicinal preparations of iron. For the method of preparing them, the reader is referred to Neligan's *Medicines*, 6th ed. p. 658, &c. They occur in the form of brilliant, semi-transparent, reddish-brown scales, and are soluble in about their own weight of water at 60°. *Tartrate of potash and boron*, known also as *soluble tartar* (although the term has also been applied to tartrate of potash), or *soluble cream of tartar*, $KO,BO_3,\overline{T}$, has been employed medicinally, but is not now used.

Tartrate of antimony and potash, known also as *tartarized antimony* and *tartar emetic*, $KO,SbO_3,\overline{T}_{10} + 2Aq$, is one of the most valuable articles in the whole *Materia Medica*. This salt, obtained by a process which is given in the Pharmacopœia, occurs in the form of square prisms, which are soluble in about 15 parts of cold water and in 2 parts of boiling water. This salt is somewhat efflorescent, and when dried at 212°, loses all its water of crystallization; its solution slightly reddens litmus, throws down an orange-colored sulphide of antimony, if a current of sulphuretted hydrogen is passed through it, and has a very peculiar nauseous, metallic taste.

There is no very delicate test for tartaric acid. Its presence in a moderately strong solution may be detected by the addition of acetate of potash, when a sparingly soluble bitartrate is soon separated, especially if the mixture be well stirred. All the tartrates on charring emit a peculiar odor resembling that of burned sugar.

A remarkable metameric modification of tartaric acid is known as *racemic* or *paratartaric acid*, $2HO,C_8H_4O_{10} + 2Aq$. It is a frequent associate of tartaric acid, but is especially abundant in the grapes of the Vosges district. While in most respects it exhibits a close resemblance to tartaric acid (the two acids having the same composition, yielding, when exposed to heat, the same products, and their salts corresponding in the closest manner), it may be distinguished and separated from it by the following points of difference. It crystallizes more readily from solution; it contains two equivalents of water of crystallization; it is less soluble in alcohol; and the racemate of lime is soluble in hydrochloric acid, and is precipitated unchanged on adding ammonia. Its most important difference, however, is, that its solution does not rotate the plane of polarization, while a solution of ordinary tartaric acid exerts a well-marked right-handed rotation.

The brilliant researches of M. Pasteur on the optical and chemical properties of tartaric and racemic acids, have opened up a new and most important field of investigation in relation to the molecular composition of organic bodies. We shall give the briefest possible abstract of his remarable discoveries, and must refer

for fuller information to his numerous Memoirs in the *Comptes Rendus, Annales de Chimie,* and other French scientific journals. He has proved that racemic acid is a mixture of ordinary tartaric acid (to which, from its optical property, he applies the term *dextro-racemic acid*) and of an acid which produces left-handed rotation, to which he gives the name *lævo-racemic acid.* (These acids are also known as *dextro-tartaric* and *lævo-tartaric acids.*) He found that, by saturating racemic acid with soda and ammonia, and allowing this solution to crystallize slowly, two varieties of crystals are obtained, which may be distinguished by their form, in the same way as the image and the reflection of the image in a mirror differ; or as right-handed and left-handed. If the two kinds of crystals are separated, and then dissolved, each solution is found to act powerfully on polarized light, but in opposite directions. On separating these acids from their bases, and mixing equal parts of concentrated solutions of each, racemic acid is again formed, which exerts no action on a polarized ray. M. Pasteur has subsequently made the discovery, that racemic acid may be artificially produced by the action of heat upon certain compounds of tartaric acid (such as tartrate of cinchonine or tartaric ether), which are capable of resisting a high temperature. The formation of racemic acid in this way is accompanied by the production of another modification of tartaric acid, which he calls *inactive tartaric acid,* which, like racemic acid, has no action on polarized light, but, unlike it, cannot be resolved into dextro and lævo racemic acids.

Tartaric acid and the tartrates, in their relation to medicine, are of considerable importance. Pure *tartaric acid,* in small doses diluted largely with water, forms a good refrigerant drink in febrile and inflammatory affections, and is much employed for this purpose in hospitals, &c., as being cheaper than citric acid. It has been stated that persons addicted to habitual drunkenness have been reclaimed by the following treatment. A few crystals of the acid are dissolved in two small tumblers of water, and taken in the morning fasting, an hour intervening between the tumblers. The painful feeling of sinking and craving of the stomach, of which such persons usually complain, is said to be removed by these acid draughts. Under the name of *acidulated drops,* lozenges composed of this acid, sugar, and oil of lemons, are largely employed in mild sore throats and colds. The principal medical use, however, of tartaric acid, is in the preparation of effervescent draughts, when added to alkaline carbonates; and in the composition of Seidlitz Powders (q. v.). *Tartrate of potash* is a mild but efficient purgative in doses of from two to six drachms, which is perhaps hardly so much used as it deserves. In passing through the system, it becomes converted into carbonate, and thus renders the urine alkaline. *Acid tartrate,* or *bitartrate of potash,* commonly known as *cream of tartar,* in full doses, acts as a sharp purgative, but is generally prescribed with some of the milder vegetable cathartics. When administered in small repeated doses (from a scruple to a drachm), in a large quantity of water, it largely increases the secretion of urine, and is consequently of great service in dropsy. It may be agreeably given in either of the following forms: (1) *Imperial,* which is prepared by dissolving a drachm of cream of tartar in a pint of boiling water, and flavoring with lemon-peel and sugar. In incipient dropsy, a couple of tumblers of this mixture, with half a glass of good hollands in each, are strongly recommended by Dr. Neligan as an after-dinner drink. The proportion of cream of tartar to the pint of water may be gradually increased to two drachms.

(2) *Cream of tartar whey* is prepared by boiling 100 grains of the salt in a pint of new milk, and removing the curds by straining. Either of these drinks may be safely taken to any extent agreeable to the patient. *Tartrate of iron and potash,* the *Ferrum tartaratum,* or *Tartarated iron,* of the Pharmacopœia, is a mild chalybeate tonic, which, in consequence of its somewhat sweet taste, is well adapted for children. It occurs in transparent scales of a deep garnet color, is soluble in water, and sparingly soluble in spirit. The dose varies from five grains to a scruple, three times a day, either given with honey or treacle, or dissolved in some aromatic water. The *wine of iron* (*Vinum Ferri* of the *Pharm. Brit.*) consists of sherry with tartrated iron in solution. Each drachm ought to contain one grain of the salt. The *tartrate of iron and ammonia,* or *ammonio-tartrate of iron,* closely resembles in its action the tartrate of iron and potash. Although not in the *Pharm. Brit.,* it is 'an excellent preparation of iron, void of all astringency. Its not disagreeable taste, its solubility in water, its compatibility with the alkaline carbonates, and the permanency of its composition, give it an advantage over most of the other preparations of iron. It is peculiarly suited as a tonic for those derangements of the uterine organs in which ferruginous salts are indicated.'—Neligan's *Medicines,* 6th ed. p. 645. The dose is from five to eight grains, and it may be prescribed in the form of powders, pills, or solution; or made into a bolus with honey. *Tartar emetic,* in doses of from one-twelfth to one-sixth of a grain, frequently repeated, acts as a diaphoretic or sudorific; nausea sometimes accompanies the diaphoresis, but it has the advantage of increasing the tendency to perspiration. The addition of the compound tincture of lavender tends to prevent the supervention of vomiting. Tartar emetic in these small doses is of great service in febrile disorders, in the hæmoptysis of phthisis, in obstinate cutaneous diseases, &c. *Antimonial wine* consists of sherry holding tartar emetic in solution in the proportion of two grains to the ounce. The dose, to produce a diaphoretic action, is 20 or 30 minims every hour. If we require an expectorant action—as in acute pneumonia or bronchitis—the salt should be given in still smaller doses, as from one-sixteenth to one-twelfth of a grain.

Tartar emetic, in doses of two or three grains, dissolved in water, acts as a powerful emetic, and at the same time produces much nausea and depression, and not unfrequently purging. The vomiting seldom occurs till about twenty minutes after the draught has been taken. If tartar emetic is thus given at the commencement of febrile or inflammatory affections, it will often cut short the impending disease. With this view, it is employed in continued fever, croup, whooping-cough, &c. It used to be given to relax the muscular system, in cases of strangulated hernia and dislocation; but chloroform is far better for these objects. In cases of poisoning, it is inferior to sulphate of zinc. It is expedient to take the emetic dose in parts, as too powerful an effect is thus prevented. Two grains, which are generally sufficient, must be dissolved in eight ounces of water, of which a quarter should be taken every ten minutes till vomiting ensues. The patient should walk gently about his room between the doses. If a large dose (of one, two, or even three grains) be repeated every second hour, the nausea, vomiting, and purging (which often follows a full dose) cease after two or three such doses, and the main action seems to be exerted in depressing the circulation and lowering the pulse. Hence, tartar emetic given in this way is a direct sedative or contra-stimulant, and is of great service in pneumonia and pleurisy. 'As a contra-stimulant,' says Neligan, 'tartar emetic is given in doses of from half a grain to two grains every hour or second hour, dissolved in one or at most two ounces of orange-flower water.' The first dose or two should not exceed half a grain, and the patient should not be permitted to drink, so as, if possible, to avoid the production of vomiting. When once a tolerance of the medicine is produced in the system, the quantity taken may be rapidly increased.'—*Op. cit.,* p. 418.

Lastly, tartar emetic, when applied to the skin, produces a crop of pustules, which ulcerate, and discharge purulent matter. In consequence of this property, tartar emetic, either in the form of ointment or of saturated solution, is often employed as a counter-irritant in various affections of the viscera of the chest and abdomen, in diseases of the joints, &c. The *ointment* is applied by rubbing about half a drachm on the skin night and morning. In two or three days, pustules begin to appear, when the further application of the ointment should be temporarily suspended. The saturated solution is a cleaner preparation than the ointment, and acts more speedily. It is applied by means of pledgets of lint soaked in it. Tartar emetic, in excessive doses, or in small repeated doses, acts as an irritant poison. Dr. Taylor has reported 37 cases of poisoning by this agent, of which 16 were fatal. The smallest fatal dose was in a child *three-quarters of a grain,* and in an adult *two grains,* but in the last case there were circumstances which favored the fatal action of the poison. The symptoms occurring in chronic poisoning by this salt are 'great nausea, vomiting of mucus and liquids, great depression, watery purging, followed often by constipation of the bowels, small contracted and frequent pulse, loss of voice and muscular strength, coldness of the skin, with clammy perspiration, and death from complete exhaustion.' A considerable number of cases are on record in this country in which murder has been perpetrated by the slow action of tartar emetic. The most important of them are referred to by Dr. Taylor in his *Medical Jurisprudence,* pp. 146 and 250, to which must be added the Pritchard case in Glasgow (1865). The *Pharmaceutical Journal* for October 1865 contains directions, by Messrs T. and H. Smith of Edinburgh, for preparing an antidote to be prescribed after a large dose of tartar emetic has been taken. The ingredients are a solution of perchloride of iron and calcined magnesia.

TA'RTARS, or, more properly, TATARS, was originally a name of the Mongolic races, but came to be extended to all the tribes brought under Mongolic sway by Genghis Khan and his successors, including Tungusic and Turkic races. The term is therefore not to be considered as ethnological, though all, or almost all, the peoples included under it, in its widest sense, belong to the Turanian family, but is rather to be understood in the same sense as the term 'Franks' used by Mohammedans. In the classification of languages, Tataric has become the distinctive name of that class of Turanian languages of which the Turkish is the most prominent member, while the Mongolic form a separate class. See TURANIAN LANGUAGES.

TA'RTARUS (Gr. *Tartaros;* the name is probably onomatopœic, the reduplication being designed to express something *terrible* or

disagreeable, like *Barbaros*, *Karkaron*, and many other words), according to Homer, is a deep and sunless abyss, as far below Hades as earth is below heaven, and closed in by iron gates. Into T., Zeus hurled those who rebelled against his authority, as, e. g., Kronos and the Titans. Afterwards the name was employed sometimes as synonymous with Hades or the under-world generally, but more frequently to denote the place where the wicked were punished after death—Lowest Hell, in fact. A noticeable feature about these punishments is their congruity with the nature of the offences perpetrated. See HEAVEN and HELL.

TA'RTARY (properly TATARY) is the name under which, in the middle ages, was comprised the whole central belt of Central Asia and Eastern Europe, from the Sea of Japan to the Dnieper, including Mantchuria, Mongolia, Chinese Turkestan, Independent Turkestan, the Kalmuck and Kirghis steppes, and the old khanates of Kasan, Astrakhan, and the Crimea, and even the Cossack countries; and hence arose a distinction of T. into European and Asiatic. But latterly the name T. had a much more limited signification, including only that tract bounded on the N. by Siberia, and on the S. by China and Tibet, along with Independent Turkestan; and at the present day, many writers apply it as a synonym for Turkestan (q. v.).

TARTRA'LIC ACID. See TARTARIC ACID.

TARTRE'LIC ACID. See TARTARIC ACID.

TARTUFE, the name of the chief character in Molière's most celebrated comedy, which has become a synonym in all languages for a hypocritical pretender to religion. The original of the character was most probably a certain Abbé de Roquette, a parasite of the Prince de Conti. The name is said to have suggested itself to Molière on the occasion of a visit to the papal nuncio, where he saw the pious and solemn countenances of the nuncio's courtiers suddenly lighted up with ecstatic animation by the appearence of a seller of truffles—in Italian, *tartuffoli*. This play excited a greater commotion than perhaps any other production of the kind ever did. It was written in 1664; but before it was brought on the public stage, partial representations of it in private companies had made its character known, and raised the alarm of the priests, who believed themselves to be specially satirized therein. Uniting with the many enemies whom Molière had already made for himself by lashing physicians, fops, and fools of all kinds, they used every means in their power to prevent the public representation of the play. The Archbishop of Paris threatened with excommunication all actors who should take any part in the performance, and even those who should only read it; and one dignitary went so far as to declare that Molière—whom he called a devil in human form—was deserving of the stake. It was not till 1669 that Molière succeeded in getting the play publicly acted in presence of Louis XIV.; and then it had an uninterrupted run for three months, to the great vexation of all hypocrites.

TASHKA'ND, till recently a town of Independent Turkestan, but now in the possession of Russia, is situated in the khanate of Khokan, 92 miles north-north-west of Khokan, the capital, on the north bank of the Saralka, a small feeder of the Djirhik River, an impetuous torrent, which empties itself into the Sir-Daria. It is the chief commercial town in the district, is the center of the transit-trade between Bokhara, Khokan, and Chinese Tartary, and has extensive trading relations with Orenburg and Petropavlovsk. Like most of the cities of Central Asia, it stands in a fertile plain. It covers a large tract of ground, being said to extend 10 miles in one direction and 5 in another, and is protected by a high wall of sun-dried bricks. Within the walls are numerous gardens and vineyards, interspersed among the houses; the houses themselves are built of mud, and thatched with reeds. The streets are narrow and dirty. The chief buildings are the castle (which is fortified), various mosques, colleges, old temples, and a bazaar. The chief manufactures are gunpowder, silk and cotton goods, and iron. According to a census taken in 1871, the population amounted to 78,125. T. is also important in a military point of view, and, mainly for this reason, had been long coveted by Russia. The Russians, who captured it in 1854, and retained it for a short time, finally took possession of it in 1865, having in the meantime made great advances in Central Asia. The petition of the inhabitants, that they might be received as Russian subjects, was granted in 1866; and since then it has been governed by a kind of municipal board, the president being a Russian officer, and the members chosen by the townspeople.

TASMA'NIA, formerly VAN DIEMEN'S LAND, a considerable island in the South Pacific Ocean, between the parallels of 40° 40′—43° 40′ S. lat., and between 144° 30′—148° 30′ E. long., lying to the south of, and separated from Australia by Bass's Strait. Its greatest length, from Cape Grim, on the north-west, to Cape Pillar, on the south-east, is 240 miles; and its greatest breadth from east to west, 200 miles; its area, including the adjacent islands, about 26,300 sq. miles. The capital is Hobart Town (q. v.), now called simply Hobart, with a pop. of 21,200. The second town is Launceston (q. v.), with a pop. of 12,750. In the year 1854, the population consisted of—males, 30,613; females, 28,261; total, 64,874. At the census of 1871, the total pop. was 99,328; at that of 1881, 115,705, (61,162 males, and 53,543 females). The majority are native born; some 30,000 were born in the United Kingdom; about 1000 are Germans; and 1000 men are Chinese. Of the inhabitants, about 5000 are mechanics and artisans, about 5000 domestic servants, 6000 farmers, 11,000 farm-laborers, 4000 other laborers, 200 miners, 90 doctors, 80 lawyers.

Physical Features.—The island, which is mountainous and well watered by rivers, has much beautiful scenery, and is much liker home than the other Australian colonies. Its south-eastern coast is deeply indented by the estuaries of the Derwent and Huon, Storm Bay, the inlet of Pitt Water, and Frederick Henry Bay. The last is protected on the south-east by Tasman's Peninsula, reserved as a penal settlement for the colony. The chief indentations on the west coast are Macquarie Harbor (formerly a penal settlement, but now uninhabited), and Port Davey. On the east coast are Oyster Bay, between Freycinet's Peninsula and the mainland; and Spring Bay, sheltered on the east by Maria Island. On the north coast, besides the estuary of the Tamar, there are numerous smaller harbors and rivers, accessible to vessels of from 30 to 300 tons. The chief of these are Circular Head, Port Sorell, and the rivers Mersey, Forth, Leven, Don, and Inglis. The scenery is of a bold mountainous character, varied by deep narrow valleys, extensive undulating tracts of country, and open plains of limited extent. Among the principal mountains are Ben Lomond (5010 feet), Cradle Mount (5069 feet), Ironstone Mount (4736 feet), Mount Barrow (4644 feet), Mount Wellington (4166 feet), with many others exceeding 4000 feet in height. Embosomed among the central mountains, at an average height of about three thousand feet, are numerous lakes, with a united area of about 170 sq. m., which feed the greater part of the rivers draining the south-east slope of the island. With the exception of the reclaimed lands, the basaltic plains, and limited tracts which are unfavorable to the growth of timber trees, the whole island is more or less densely wooded. The vast forests of the western portions of the north and south coasts are extensively utilized for timber, and in the former, the work of reclaiming the rich heavily-timbered lands is rapidly progressing. But the major part of the western half of the island is entirely uninhabited, its soil, climate, and inaccessible position offering little inducement to the settler.

Geology and Mineralogy.—The bed-rocks of the western districts, from Bass's Strait to South-west Cape, consist of vast bands of slates, schists, and quartz rock, belonging to the Azoic or Metamorphic series. Next to these come Lower Palæozoic slates, with conglomerates and dark compact limestones, the latter highly charged with Silurian fossils. Unconformably upon the upturned edges of these rocks lie Upper Palæozoic sandstones, mudstones, limestones, and conglomerates, also traversed by dykes and masses of greenstone and basalt, and with these, reaching an altitude of 4000 feet above the sea-level. In the south-east districts, from the South Esk River on the north to the Huon on the south-west, the lower rocks are entirely absent, or concealed beneath the Upper Palæozoic beds. In the north-east district, the lower rocks again make their appearance, associated with granite and greenstone, and occasionally traversed by dykes and veins of the true auriferous quartz. Here, again, they are overlaid by Upper Palæozoic rocks, extensively denuded, and exposing seams of coal from 2 feet to 14 feet thick, at various elevations. Tertiary rocks are sparingly distributed. At the mouth of the river Inglis, on the north coast, are beds of a whitish freestone, attaining in places a thickness of 120 feet, and containing recent shells, with extinct species of *Trigonia*, *Terebratula*, *Cypræa*, *Voluta*, &c. Tertiary lignites are found in the sandy clays of the valleys of the Derwent and Tamar, with impressions of leaves of unknown trees and plants. Over the greater part of the basin of the South Esk, comprising an area of more than 1000 sq. m., extensive deposits of clays, sands, and quartz drift are met with. No distinct traces of glacial action have been observed; but the thick beds of gravel, and the boulders, which must have traveled many miles from their parent rock, afford evidence of some powerful transporting agency, and were probably deposited in their present sites by the action of icebergs slowly drifting northwards at some period prior to the last general elevation of the land.

The igneous rocks are everywhere present in great variety. The islands of the Furneaux group in Bass's Strait, are chiefly of granite, and form the connecting links which join the north-east angle of T. to the Great Dividing Range of Eastern Australia. Gold has been found in many places, and the workings have for years given fair returns to a limited number of miners. In 1880, the value of the gold (alluvial and drift) produced was £201,297. Silver and antimony have been met with in the gold-drifts, and very rich deposits of tin began in 1872 to be worked at Mount Bischoff, the richest tin mine in the world, which yielded 1050 tons of ore from January to June 1880. Copper occurs in thin veins, associated with galena, on the north coast, and galena is found

elsewhere in the primitive limestones. Red and brown hæmatites, containing a large percentage of iron, occur at various points on the north coast, in large masses and lodes. In 1880, 3987 tons of ironstone were raised; and iron-works on an extended scale are now in operation. Coal is worked in several parts of the island, chiefly for local consumption. A large lode of bismuth was discovered in 1875. The older limestones yield fine varieties of marble, and excellent building-stone is obtained from the greenstones, basalts, and Palæozoic sandstones.

Botany.—The flora of T. has been fully described in the botany of the antarctic voyages by Hooker and others. The majority of the species are common to Australia and Tasmania. Of those which are peculiar to the latter, many are limited to particular localities. The most widely diffused genera are the Eucalypti and Acaciæ, the former yielding the ordinary timber of the colony. The Blue Gum (*Eucalyptus globulus*) reaches a height of 350 feet, with a corresponding girth. The Black-wood (*Acacia melanoxylon*) and the Huon Pine (*Ducrydium Franklinii*) also yield valuable timber, which, together with the hardwoods from the Eucalypti, is largely exported to the neighboring colonies.

A species of Beech (*Fagus Cunninghamii*), locally known as the myrtle, and growing in great abundance in some parts of the island, also produces a highly valuable timber, which has not yet received the attention which it merits. There are many beautiful shrubs and plants, but the flowers are usually small and inconspicuous. All the common fruit-trees and culinary vegetables of England have been introduced, and grow with great luxuriance and vigor. Oranges and lemons are cultivated in some situations, but do not usually ripen their fruit. The introduction and cultivation of exotic trees and plants is energetically carried on in the Botanical Gardens under the direction of the Royal Society.

Zoology.—Of the 30 species of mammals, one-half belong to the sub-class *Aplacentaria*, comprising the *Marsupiata* (kangaroo, wallaby, opossum, wombat, &c.), and two species of the singular order *Monotremata* (Ornithorhynchus and Echidna). Among the marsupial animals peculiar to T., the chief are the Thylacine (*Thylacinus cynocephalus*) and the Tasmanian Devil (*Dasyurus ursinus*), both of which are sometimes very destructive to sheep in the outlying districts. The skin of the kangaroo is much prized for leather, and there is always a market for opossum fur. Whales and seals, formerly very abundant on the coasts, are now rare; but whaling is still extensively carried on in the adjacent seas. The birds of T. have been admirably described by Gould. The majority are identical with Australian species. The emu is extinct, and black swans are seldom seen in the settled districts. There is abundance of native game, which is now protected by act of parliament during the breeding season. A species of puffin (*Puffinus brevicaudus*), locally known as the mutton-bird, frequents some of the islands in Bass's Strait, in countless numbers, and many thousands are annually slaughtered for the sake of their oil, and for food by the half-caste islanders. Fish are plentiful in the seas and rivers, the best being known by the local name of trumpeter, and reaching a weight of 40 lbs. There are 13 species of snakes, most of which are venomous, but accidents from their bite are of very rare occurrence. Many species of insects and crustaceans have been described by Erichson, Gray, Gunther, and others. A comprehensive and accurate account of the *fauna* of T. is still, however, a desideratum.

Fallow deer, and several of the English game-birds, have long been naturalized, and salmon have been introduced after several unsuccessful attempts.

Climate, Soil, Produce, &c.—The climate of T. is fine and salubrious. From observations taken at Hobart Town, and extending over a period of twenty years, the extreme of heat appears to be 105°, and of cold 29° 8′. The mean temperature of the hottest month (January) is 63° 57′, and of the coldest (July) 45° 82′, and of the whole year, 54° 92′. In some parts of the island, the temperature, even in winter, rarely sinks to 45°. Snow seldom falls in the settled districts, and does not lie on the ground except on the high table-lands of the interior. The average annual rain-fall at Hobart Town is 21·52 inches, and the average for the rest of the island about 35 inches, except in the western country and the high lands, where a fall of 75 inches has been registered in the year.

The agricultural lands may be divided into three classes—alluvial deposits, tertiary clays, and loamy soils, derived from the decomposition of different kinds of basalt. In their virgin state, some are marvelously productive. On new land, 100 bushels of oats, 70 bushels of wheat, and 15 tons of potatoes per acre, are not uncommon crops. The fertility of the soil has encouraged a system of slovenly farming. In many instances the land has been cropped with wheat and oats for upwards of thirty years without any application of manure, or any rest save an occasional summer fallow. The export trade in the staple articles of produce has much fallen off of late years, partly because the neighboring colonies have begun to depend more upon their own resources, but partly also through the deterioration of the soil from improvident management, and the necessarily increased cost of production. There are skilled and careful farmers in every district, but they are exceptions to the rule. The open pastoral lands are admirably adapted for sheep. The wool from some of the larger establishments is much valued, and brings the highest price in the London market. The cattle and agricultural horses of some of the northern districts are unsurpassed in the colonies. Pastoral and agricultural associations have been formed to promote improvements in the system of farming, and to encourage the breeding and importation of pure stock.

The extent of alienated land is over 4,000,000 acres of which about 380,000 are cultivated. The chief crops are wheat, oats, barley, potatoes, peas, and hay; also hops. Fruit of all kinds is largely grown and exported; and fruit-preserving is an important industry. In 1880–81, 50,000 acres were in wheat, and the yield was 750,00 bushels. There were then upwards of 25,000 horses, 127,000 cattle, 1,780,000 sheep in the colony. The exports, of which wool is the chief, had in 1880 a value of £1,511,-931; the imports, of £1,369,224. There are breweries, tanneries, soap-works, flour-mills, agricultural implement works, coach-works, and one tweed manufactory. The Tasmanian ale is excellent, and is exported to Victoria, and New South Wales. The protective tariffs of Victoria, and the consequent loss of market, is the chief hindrance to the prosperity of T. The whale-fisheries used to be of value to T., but have fallen off. In 1880, the colony possessed 207 sailing-vessels of 18,820 tons and 15 steamers of 4590 tons; and 654 vessels, of 205,217 tons, entered; while 655, of 208,806 tons, cleared the ports of the colony.

Administration.—Since the passing of the 'Constitutional Act' in 1854, the governing authority has been vested in a parliament, consisting of the governor as the Queen's representative, and two elective Houses, the Legislative Council of 16, and the Assembly of 32 members. The qualification of voters is, for the former, a freehold of the annual value of £30, or a leasehold of £200; and for the latter a freehold of the value of £50, or the payment of £7 house rental. Graduates of British universities, and all holding a commission in the army or navy, or in holy orders, are entitled, *ex officio*, to vote at the election of members of both Houses.

The land laws of T. are liberal. Any immigrant who has paid the passage of his family, may demand 30 acres for himself, 20 for his wife, and ten for each of his children. Unmarried immigrants receive land orders for the value of £18. The upset price of agricultural land is £1 per acre, the average price paid in 1880 being about £1, 6*s.* for country land. Town land is worth about £6 per acre. Pastoral land may be had for 5*s.*

The revenue of T. in 1880 was £444,845, the expenditure being £427,712. The public debt was £1,943,700, of which £1,289,000 had been incurred for public works, including railways. The railways are the main line from Hobart to Launceston (133 miles), and the Launceston and Western (45 miles). Other two short railways have been projected.

Religion and Education.—There is now no parliamentary grant for the support of religion, though till lately £15,000 was divided among the various religious denominations according to their respective numbers at the census. By a return in 1870, there were: Church of England, 53,047; Roman Catholics, 22,091; Presbyterians, 9064; Wesleyans, 7187; Independents, 3931; Baptists, 931; Jews, 232. The higher branches of education are under a council, the lower under a board; and public instruction is carefully and liberally fostered. In 1854, the number of schools was 50, and the average attendance of pupils, 2624. In the beginning of 1880 there were upwards of 170 schools supported by government, 320 teachers, 12,286 children on the rolls, with an average daily attendance of 6002. Of the entire population about 60 per cent. can both read and write; about 25 to 30 per cent. are unable to read.

For the promotion of higher education, provision is also made by the legislature. Two scholarships, each of the value of £200 a year, and tenable for four years at either of the English universities, are annually open to competition under the direction of the Council of Education, and exhibitions to the higher schools, with other local honors, are periodically awarded by the same body.

Aborigines.—The number of the aborigines at the first colonization of T. has been variously estimated, but probably at no time exceeded 3000. There were several tribes occupying distinct parts of the island, and differing from each other in dialect and customs; but of a generally uniform type more nearly allied to the Negritos of New Guinea than to the aborigines of Australia. The average height of the men was from 4½ to 5½ feet; of the women, considerably less. Color, a bluish black; the facial angle 75° to 80°; eyes, dark brown, with jet-black pupils; hair, sometimes lank, but generally crisp or woolly; forehead, high and narrow; limbs, lean and muscular; feet, flat and turned inwards. Polygamy appears to have been tolerated: the women performed all menial duties, and were specially charged with that of carrying fire from place to place, when the temporary encampment was broken up. Their usual shelter was a 'break-wind,' constructed of

boughs, but traces of rude huts have been observed. In summer, they went entirely naked, at other times wearing coverings made from the skins of the kangaroo and opossum, which formed their chief food. The coast tribes, at certain times of the year, lived almost exclusively on shell-fish, and the remains of their feasts have often been mistaken for recent marine deposits. Among other articles of food were the roots of the esculent fern, the heart of the tree-fern, and grass-tree (*Xanthorrhœa*), the seeds of the boobialla (*Acacia sophora*), and a singular fungus (*Mylitta Australis*) commonly known as 'native bread,' which grows under ground near the roots of decayed trees. No traces of cannibalism were observed. Their only weapons were the spear and waddy, a wooden club about 2 feet 4 inches in length. The early relations between the settlers and aborigines were friendly; but as the latter were gradually dispossessed of their favorite hunting-grounds, they became inveterately hostile. Shot down without mercy by the settlers, they revenged themselves by bloody reprisals, and for many years the unequal struggle continued, until their numbers were reduced to a few hundreds.

In 1830, an attempt was made to drive the whole body into Tasman's Peninsula, by means of a cordon extending across the whole island, and gradually closing in towards the south-east; but it failed ridiculously, as might have been foreseen. In the following year, Robinson, a builder of Hobart Town, undertook to conciliate the surviving remnants of the various tribes, with a view to their removal to Flinders Island, and this he successfully accomplished, after four or five years of patient, self-denying labor. In spite of all the care bestowed upon these unfortunate people, their numbers rapidly decreased, and only 45 remained when the settlement was removed, in 1847, to a more convenient station at Oyster Cove, near Hobart Town. There were in 1865 only six remaining. No children had been born among them for many years, and the race is now wholly extinct, the last of the number having died a few years ago.

History.—The island was first discovered by Tasman on the 1st December 1642, and named by him Van Diemen's Land, in honor of his patron, the then governor of the Dutch possessions in the East Indies. During the next century, no visit is recorded; but between 1772 and 1802, partial surveys and explorations were made by English and French navigators. In 1803, Lieutenant Bowen was dispatched from Sydney with a few soldiers and convicts to form a settlement in the south of T., which was finally fixed on the spot where Hobart Town now stands. In 1804, a settlement was formed near the mouth of the Tamar, which was removed in 1806 to the spot now occupied by the town of Launceston. From 1817, commenced a rapid increase in the number of free settlers, who received grants of land in proportion to the capital which they brought into the colony, and were subsequently further aided in the clearing and cultivation of their estates by the assignment of convicts as their servants. In 1825, T. was declared independent of New South Wales.

The colony was for a good many years agitated by the question of the disposal and management of the convicts, who were now becoming a prominent and formidable element in the community. At last, in 1853, transportation to T. and New South Wales was finally abandoned by the home government. The abolition of transportation, and the consequent cessation of a vast imperial expenditure, naturally produced a considerable depression in all branches of trade, especially in the southern districts. It is not surprising that the great body of the colonists, instead of setting themselves manfully to turn the true and natural resources of the country to the best account, have rather looked for some great discovery of rich gold-fields, or some gigantic works undertaken under the auspices of government, as the only means by which the prosperity of the colony was to be assured. But such a state of things must ultimately work its own cure. Viewed in a true light, the progress, social, material, and political, has presented a more hopeful aspect since the extinction of the convict system than at any earlier period. For years after the discovery of gold in Australia, the *expirees* of T. flocked in crowds to the neighboring colonies, attracted by the prospect of richer gains, and glad to escape from police surveillance in a country where their antecedents were too well known. Those who remained had, for the most part, by this time become orderly, well-conducted members of the community, not to be distinguished from the immigrant population by whom they were surrounded. Necessity will in due time develop the enterprise and energy which have too long lain dormant. Some of the older settlements may prove inadequate to the maintenance of their former population, but the rich lands of the north coast offer to industrious settlers a field which is practically inexhaustible.

TASMA'NNIA, a genus of shrubs of the natural order *Magnoliaceæ*. *T. aromatica* is an evergreen bush of Van Diemen's Land, growing in the richest soils on the margins of rivers and in shady ravines, and sometimes forming thickets of large extent. Every part of the plant is highly aromatic and pungent. The fruit is occasionally used as pepper. This shrub requires protection from frost in England.

TASSISUDO'N, the capital of Bhoton (q. v.), stands on the right bank of the Godadda, an affluent of the Brahmaputra, in lat. 27° 30′ N. Many of the inhabitants, the number of whom has not been ascertained, are employed in manufacturing paper, and in making brass images and ornaments for their places of worship.

TASSO, Bernardo, an Italian poet of considerable distinction, but most famous as the father of the illustrious Torquato, was born at Bergamo, 11th November 1493. Both by his father's and mother's side, he was connected with the ancient family of the Tassi, known in the 13th c. for having organized and superintended the postal service in Italy, Spain, and Germany. His uncle, Luigi Alessandro, Bishop of Recanati, took charge of his education, and under his care he turned out a fine classical scholar, his love of poetry at the same time becoming every year more ardent. The assassination of the cardinal, in 1520, deprived him at once of protection and support, and for several years he wandered about Italy in a rather necessitous condition. Like his son, he was exceedingly fond of the patronage of noble lords and the smiles of noble ladies. After 1525, we find him high in favor with persons of influence. Guido Rangone, general of the pontifical forces, intrusted him with several missions, among others to the Prince of Salerno, who appointed him his secretary; and T. accompanied the prince on the expedition against Tunis in 1534. In 1539, he married, at Salerno, a young lady of Sorrento, Porzia de' Rossi, who added genuine merit to the advantages of birth, beauty, and fortune, and by whom he became the father of Torquato. The fall of the Prince of Salerno (who had incurred the enmity of Charles V.) brought with it the ruin of T.'s worldly prosperity, and he was obliged to seek for a new patron. He was not long in finding friends. Guidubaldo, Duke of Urbino, and Gugielmo, Duke of Mantua, strove for the honor of attaching the poet to their court. The latter succeeded, and named him governor of the city of Ostiglia, where he died 4th September 1569.

T.'s principal writings, chronologically arranged, are: *Rime* (Ven. 1531); *I tre Libri degli Amori* (Ven. 1537); *Ode e Salmi* (Ven. 1560); *L'Amadigi, Poema* (Ven. 1560); and *Il Floridante, Poema* (Mant. 1587). Of these, the principal is *L'Amadigi* (Amadis), which some Italian critics have not hesitated to place above the poem of Ariosto; but without adopting this extravagant estimate, we may justly admire it for the sweetness and elegance of its language, and for the beauty of its descriptions and comparisons.—For a good idea of the politics and literature of the time, see Seghezzi's edition of his *Lettere* (3 vols., Padua, 1733—1751), to which there is prefixed a biographical notice.

TASSO, Torquato, one of the greatest poets of Italy, was the son of the preceding, and was born at Sorrento in Naples, 11th March 1544. His earliest education was received from the Jesuits. During his childhood, T.'s father was an exile, but the affectionate solicitude of his mother well supplied the want of paternal care. In 1554, he went to Rome to join his father, and left his mother (whom he was destined never again to see) in a convent at Naples. At Rome, and subsequently at Bergamo, Urbino, Pesaro, and Venice, he continued to prosecute his studies. He assisted his father in copying, correcting, and even in completing his poem *L'Amadigi*, though as yet only 16 years of age. No wonder old Bernardo was delighted at the promise shown by his son, and prophesied in his letters that Torquato would yet become a great man. Later, however, sad experience of the miseries of a poet's life, induced him to send T. to Padua, to study jurisprudence under the celebrated Panciroli. But whom the gods have made poetical can never sink into a lawyer. The youth remained at Padua a year, and wrote *Rinaldo* (Venice, 1562), a poem in 12 cantos, the hero of which is the son of Aymon, and cousin of Roland. It belongs, therefore, to the class of heroic romances. After the first burst of anger was over, Bernardo forgave his son for following his example rather than his precept, and became prouder of T.'s genius than ever.

T. now betook himself to the university of Bologna, to study philosophy, and is said to have distinguished himself by an extraordinary facility in the discussion of the most elevated and abstract themes—a circumstance that perhaps says more for his power of rhetoric than his power of speculation. On leaving Bologna, he spent some time with friends at Castelvetre, Modena, and Corregio, but returned to Padua at the request of his friend Scipio de Gonzaga, afterwards cardinal, who had established a literary academy there, of which T. became a member. It was during this second residence at Padua that he conceived the first idea of his great work, the *Gerusalemme Liberata*, a heroic record of the conquest of Jerusalem by the Crusaders under the command of Godfrey de Bouillon. Lamartine beautifully describes the mingled motives of the poet: 'Urged by piety no less than by the muse, Tasso dreamed of a crusade of poetic genius, aspiring to equal by the glory and the sanctity of his songs, the crusades of the lance he

was about to celebrate.' The same critic goes on to observe, in allusion to the less noble passion for the applause of courts that marked the poet: 'The names of all the noble and sovereign families of the West would be revived in this epic catalogue of their exploits, and would attract to the author the recognition and favor of the great. . . . . Finally, the poet was himself a knight, noble blood flowed in his veins, to celebrate warlike deeds seemed, as it were, to be associating his name with those of the heroes who had performed them on the field of battle: thus religion, chivalry, poetry, the glory of heaven and earth, the hope of eternal fame, all combined to urge him to the undertaking.' Bernardo heard of his son's design with exulting joy, and blessed Heaven for making Torquato a greater genius than himself. Meanwhile (1565), T. had been introduced by Cardinal Luigi d'Este (to whom he had dedicated the *Rinaldo*) to his brother, Alfonso II., sovereign Duke of Ferrara. Here for a time he was supremely happy. Young, handsome, courteous, and with that proper tinge of melancholy in his disposition that possesses an irresistible charm for women, he soon became a universal favorite with the beauties of the court. While their bright eyes rained influence, T. painted his *Armida* and *Herminia* almost without effort.

It is only just to add, that the attempt to seek the origin of his subsequent miseries and madness in a presumptuous passion for Leonora, sister of the Duke of Este, which was first encouraged, then repulsed, and finally punished with imprisonment, is utterly at variance with the notorious facts of the case. Space does not permit us to examine the question here, but it appears necessary to correct errors of traditions so specious as to have imposed upon illustrious men. T. courted, platonically and otherwise, various ladies of the court—a pretty chamber-maid even was not beneath his notice; but there is not a vestige of evidence to show that he lifted his eyes to the sister of his sovereign, or that such a suspicion was ever harbored by the lady herself or her brother. In truth, his madness was connected in its origin more closely with his poetry than with his loves. Having finished his great epic about 1575, he sent a copy of it to a society of scholars, critics, and churchmen at Rome, to get their opinion of it. It would have been far better had he published the poem at once, without placing it at the mercy of critics who were delighted to have the opportunity of finding fault before the public was in a position to praise. The critics would then have been forced to swell the chorus of general admiration. T. was tortured by their waspish comments, and, with pitiable agonies, proceeded to make his work more agreeable to his incapable judges. Gradually a morbid melancholy overpowered his reason; the spites and jealousies that are never absent from a gay and pleasure-loving court, contributed to increase his mental disorder. He believed that invisible persecutors had denounced him to the Inquisition as a heretic.

It was in vain that Alfonso and his sisters tried to calm the perturbations of his spirit, and even got the Inquisition to write him a reassuring epistle. His paroxysms increased in violence. Finally, one evening in June 1577, he drew his dagger in the apartments of the Duchess of Urbino, to stab a domestic whom he took to be one of his secret enemies; and Alfonso had him confined in his palace and at Belrignardo for his health's sake, rather than to punish him. Next month he made his escape, and fled across the Abruzzi to his birthplace, Sorrento, where he took refuge with his sister. The air of his native place quickly restored him to health; but no sooner had he recovered, than he began to yearn for the old excitements, begged Alfonso to take him back, and when that prince drily informed him that he might return if he pleased, T. greedily availed himself of the cold permission, and was soon as wretched as before. A new flight ensued, this time towards the north of Italy. The unhappy poet wandered at last half-naked into the city of Turin, where he was humanely received by the Marquis d'Este, brother of Alfonso. After some time, he again ventured to return to Ferrara (1579), but only to madden, almost as soon as he breathed its noxious air. Alfonso shut him up in the asylum of Santa Anna in Ferrara, in which he remained upwards of seven years, suffering terribly from confinement, when the duke, at the request of the Prince of Mantua, Pope Sixtus V., and others, released him (5th July 1586). During the remainder of his life, T. lived chiefly at Naples and Rome. Almost the last incident of his career was his intended public coronation on the Capitol. The excitement was too much for his ruined frame. A slow fever seized him; he was removed to the convent of Santo Onotrio, and there, before the laurel could be conferred on him, he died 25th April 1595, after a brief illness. It should be noted that in 1570 T. visited France, where he spent a year, gaining the friendship of Charles IX.

Besides his *Gerusalemme Liberata*, transl. by Fairfax (1600), Hooke, Hoole, Hunt (1818); Smith (1851); Griffiths (1863), &c.; T. wrote a great number of works in verse and prose. In 1573, he produced his *Aminta*—a pastoral drama, one of the first and most successful of its kind, whose striking beauty led to innumerable imitations. *Rime, insiemi con altri Componimenti* (1581); *Dialoghi e Discorsi* (1587); *Lettere Familiari* (1588); *Rime* (1592—1593); and *Gerusalemme Conquistata* (1593). A complete edition of his works appeared at Pisa in 1832, in 33 vols. See Hasell's T. (1882).

TASTE, ORGAN AND SENSE OF. The principal seat of the sense of taste is the mucous membrane of the tongue, in which dissection reveals a *cutis* or *chorion*, a *papillary structure*, and an *epithelium*. Of the *cutis*, it is sufficient to remark that it is tough, but thinner and less dense than in most parts of the cutaneous surface, and that it receives the insertions of the intrinsic muscles of the tongue, which will be described when we treat of that organ generally. The *papillary structure* differs from that of the skin in not being concealed under the epithelium, but in projecting from the surface like the villi of the digestive canal, and it thus gives to the tongue its well-known roughness. The *Epithelium* (q. v.) is of the scaly variety, as on the skin, but is much thinner on the tongue than on the skin. It is most dense about the middle of the upper surface of the tongue, and it is here that, in disordered digestion, there is the chief accumulation of *fur*, which in reality is simply a depraved and over-abundant formation of epithelium. The *papillæ* on the surface of the tongue are either *simple* or *compound*. The former, which closely resemble those on the skin, are scattered over the whole surface of the tongue in parts where the others do not exist, and they likewise participate in the formation of the compound papillæ, which, from their forms, are respectively termed (1) the *circumvallate* or *caliciform*, (2) the *fungiform*, and (3) the *conical* or *filiform*.

The *circumvallate* papillæ are not more than eight or ten in number, and are situated in the form of a V at the base of the tongue. Their function seems to be to secrete mucus, as well as to take part in the act of tasting. They consist of 'a central flattened projection of the mucous membrane of a circular figure, and from $\frac{1}{30}$th to $\frac{1}{12}$th of an inch wide, surrounded by a tumid ring of about the same elevation.'—Todd and Bowman, *Physiological Anatomy and Physiology of Man*, 2d ed. vol. i. p. 437. They are shown in the figure of the surface of the tongue given in the article on that

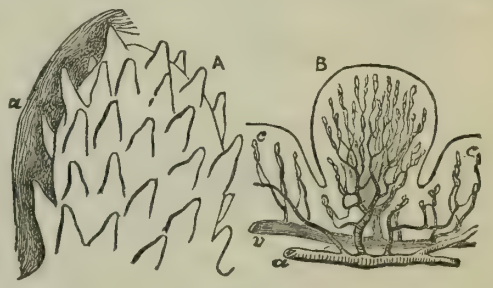

Fig. 1.

A, *Fungiform papilla*, showing the simple papillæ on its surface; and at *a*, the epithelium investing them (magnified 35 diameters) B, a similar papilla, with the capillary loop of its simple papillæ injected; *a*, artery; *v*, vein. Around the base there is often a groove, which is here shown; as also are the capillary loops, *c*, *c*, of two of the neighboring simple papillæ (magnified 18 diameters.)

organ. The *fungiform* papillæ are scattered over the surface in front of the circumvallate papillæ, and about the sides and apex. They are usually narrower at the base than at the apex, where they are about $\frac{1}{30}$th of an inch in diameter. They are covered with simple or secondary papillæ, and their investing epithelium is so thin that the blood circulating in them gives them a red color, which is not seen in the conical papillæ amongst which

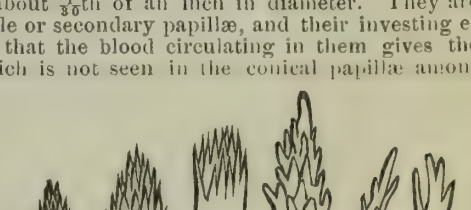

Fig. 2.—Various Forms of Conical Compound Papillæ

a, *b*, *c*, provided with the stiffest and longest epithelium, and the simple papillæ much acuminated; *d*, approximates to the fungiform, and *e*, and *f* to the simple papillæ. (Magnified 20 diameters).

they are distributed. They contain nerves terminating in loops. The shape of the *conical* or *filiform* papillæ is indicated by their names; and even if they take little part in the sense of taste directly, it is convenient to describe them here. Their average length is about $\frac{1}{10}$th of an inch. The structure of these papillæ will be better understood from the accompanying diagrams than from any verbal description. They terminate in long pointed processes, which are bathed by the mucus of the mouth, and are

capable of moving in any direction, although they are generally inclined backwards.

Some of the stiffer of these epithelial processes enclose minute hairs, of which several forms are depicted by Messrs. Todd and Bowman, from whose *Physiological Anatomy* all the figures in this article are borrowed. These authors surmise, on structural grounds, that the filiform papillæ 'can scarcely share in the reception of impressions which depend on the contact of the sapid

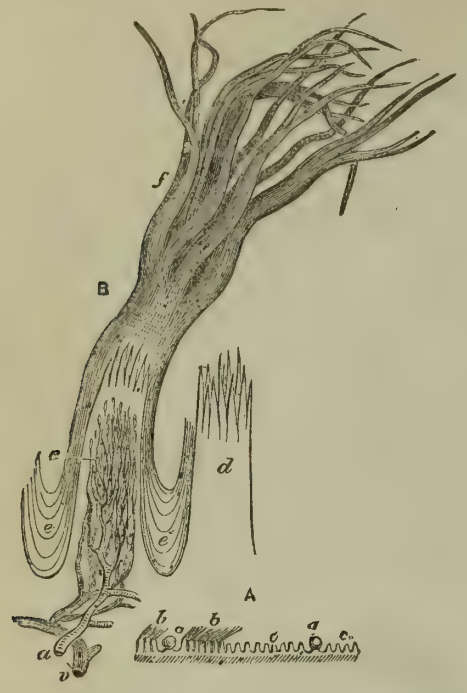

Fig. 3.

A, vertical section near the middle of the dorsal surface of the tongue, showing the basement membrane on which lie *a*, *a*, fungiform papillæ; *b*, *b*, filiform papillæ, with hair-like processes; *c*, *c*, similar papillæ devoid of these processes. B, a filiform compound papilla, magnified 300 diameters: *a*, artery; *v*, vein; *c*, capillary loop; *d*, a secondary papilla deprived of *e*, epithelium; *f*, hair-like processes at the apex.

material with the papillary tissue. The comparative thickness of their protective covering, the stiffness and brushlike arrangement of their filamentary productions, their greater development in that portion of the dorsum of the tongue which is chiefly employed in the movements of mastication, all evince the subservience of these papillæ to the latter function rather than to that of taste; and it is evident that their isolation and partial mobility on one another must render the delicate touch with which they are endowed more available in directing the muscular actions of the organ. The almost manual dexterity of the tongue in dealing with minute particles of food is probably provided for, as far as sensibility conduces to it, in the structure and arrangement of these papillæ.'—*Phys. Anat. and Phys. of Man*, vol. i. p. 441. Notwithstanding the difference in their outward form and mode of arrangement, the simple papillæ, which have been detected by Todd and Bowman as scattered over the whole dorsum of the tongue (although concealed under the common sheet of epithelium), and those clothing the circumvallate and fungiform papillæ, do not seem to present any structural difference; and their epithelium, which is very thin, readily permits the transudation of sapid substances dissolved in the mucus of the mouth. With regard to the use of the singular configuration of the circumvallate and fungiform papillæ, 'it may be conjectured that the fissures and recesses about their bases are designed to arrest on their passage small portions of the fluids in which the sapid materials are dissolved, and thus to detain them in contact with the most sensitive parts of the gustatory membrane.' —*Op. cit.*, p. 441.

There has been much discussion regarding the precise seat of the sense of taste and the true nerves of taste. Although the surface of the tongue is the special seat of gustative sensibility in man, the sense of taste is by no means restricted to that organ, being diffused, in a less degree, over the soft palate, the arches of the palate, and the fauces. Moreover, the gustative sensibility varies on different parts of the surface of the tongue. It is generally allowed that acute taste 'resides at the base of the tongue, over a region of which the circumvallate papillæ may be taken as the center, and also on the sides near the base. These parts are supplied solely by the glossal twigs of the glosso-pharyngeal nerves. Some writers, amongst whom are Valentin and Wagner, believe the middle and anterior parts of the dorsum of the tongue to be usually incapable of appreciating flavor; while numerous others hold the contrary opinion, with which our own careful and repeated experiments, on other persons as well as ourselves, quite accord. Sour, sweet, and bitter substances applied to the sides, and especially to the tip of the protruded tongue, we find to be at once distinguished; though, when placed on the middle of the dorsal region, they make little or no impression till pressed against the roof of the mouth. This region of the tongue is supplied almost solely by the lingual branch of the fifth nerve. We conclude generally, with regard to the tongue, that the whole dorsal surface possesses taste, but especially the circumferential parts, viz., the base, sides, and apex.'—*Op. cit.*, pp. 442, 443. The investigations of Messrs. Todd and Bowman further show that the soft palate and its arches are endowed with taste in some persons, but not universally, while they got no evidence in any case of gustative sensibility on the pharynx, gums, or elsewhere. The soft palate and its arches are supplied by palatine branches from Meckel's ganglion, and sparingly by the glosso-pharyngeal nerves. From (1) the evidence afforded by the anatomical distribution of the nerves to parts enjoying the sense of taste, (2) the evidence of experiments, in which the various nerves of the tongue were divided, and (3) the evidence afforded by disease, it may be safely inferred that the glosso-pharyngeal and the lingual branches of the fifth pair of nerves respectively participate in the sense of taste; and there is also reason to attribute a share to the palatine branches of the fifth.

Impressions of taste may be produced by a mechanical or chemical excitement of the gustatory nerves. A quick light tap of the finger on the tip of the tongue causes a taste, sometimes acid, sometimes saline, which lasts for several seconds; and galvanism acts similarly. If the surface of the tongue, near the root, be touched with a clean dry glass rod, or a drop of distilled water be placed upon it, a slightly bitterish sensation is produced; and if the pressure be continued, a feeling of nausea ensues. If a small current of cold air be directed against the tongue, it excites a cool saline taste like that of saltpetre. From the experiments of E. H. Weber, it appears that one of the conditions requisite for the due exercise of the sense of taste is a temperature not departing far on either side from the natural standard. Thus, if the tongue be immersed for a minute in water at a temperature of 125°, or in iced water, the taste of sugar, &c., is no longer perceived. In order that sapid bodies should cause taste, it is necessary that they should be dissolved, and made to permeate the tissue of the papillæ, so as to come in contact with their nerves. This is proved by the two following facts: 1st, that every substance, whether solid, fluid, or gaseous, which possesses a distinct taste, is more or less soluble in the fluids of the mouth, while substances which are perfectly insoluble are only recognized by the sense of touch; and 2d, that if the most sapid substance be applied in a dry state to a dried part of the surface of the tongue, no sensation of taste is excited. Bitters and acids appear to be the most sapid bodies, since they may be diluted to a greater extent than any other known substances without ceasing to excite sensations of taste. Thus, according to Valentin, 1 part of extract of aloes, or of sulphuric acid, in 900,000 of water, and even 1 part of sulphate of quinia in 1,000,000 parts of water, may, with ease, be distinguished from perfectly pure water.

'The contact of a sapid substance,' says Dr. Carpenter, 'much more readily excites a gustative sensation when it is made to press upon the papillæ, or is moved over them. Thus there are some substances whose taste is not perceived when they are simply applied to the central part of the dorsum of the tongue, but of whose presence we are at once cognizant by pressing the tongue against the roof of the mouth. The full flavor of a sapid substance, again, is more readily perceived when it is rubbed on any part of the tongue, than when it is simply brought in contact with it, or pressed against it. Even when liquids are received into the mouth, their taste is most completely discriminated by causing them to move over the gustative surface: thus, the 'wine-taster' takes a small quantity of the liquor in his mouth, carries it rapidly over every part of its lining membrane, and then ejects it.'—*Principles of Human Physiology*, 6th ed. p. 621. Most sapid substances affect the nerves of smell to a greater or less degree, as they pass down the throat; and it is this compound of taste and smell that constitutes *flavor*. It is a common habit to hold a child's nose when he is taking a nauseous draught, with the view, as is supposed, of deadening the taste. The efficacy of the process depends upon the exclusion of smell, and the reduction of the flavor of the medicine to its mere taste. The agreeable sensation produced by sipping good wine is due to what is termed its *bouquet*, or, in other words, to its flavor, or combined taste and smell. Some substances leave a taste in the mouth very different from that which they first produced. This *after-taste* is usually bitter; but in the case of one of the most bitter substances known, namely, tannin, it is sweet. This connection seems, in a degree, to correspond to the complementary colors in vision.

There can be no doubt that the sense of taste has for its primary object to direct us in the choice of food, to make the act of eating agreeable, and to excite the flow of mucus and saliva which aid the digestive process; and amongst the lower animals, the instinctive perceptions connected with this taste are much more remarkable than in man. As a general rule, it is found that those substances whose taste is agreeable are useful articles of food, and *vice versâ;* although there are some well-known exceptional cases. Sir Henry Holland, in his *Medical Notes and Reflections*, observes that in the majority of instances of actual illness, the desires of the patient as to food and drink may be safely complied with, even when some seeming extravagance of diet is suggested; and that in the early stage of recovery from gastric fevers, he has seen many curious instances of such contrariety to all rule acquiesced in with manifest good to the patient. 'Dietetics,' he adds, 'must become a much more exact branch of knowledge, before we can be justified in opposing its maxims to the natural and repeated suggestions of the stomach, in the state either of health or disease.'

TATE, Nahum, a poet and dramatist, son of the Rev. Dr. Faithful Tate, was born in Dublin in 1652, and educated at Trinity College, Dublin. In 1690, he succeeded Shadwell as poet-laureate, and held that dignity till his death in 1715. His habits were somewhat improvident, and in the latter part of his life he resided within the precincts of the Mint at Southwark, then a privileged sanctuary for debtors—hence perhaps that 'down-cast look' and inability to 'say much for himself,' for which, it is said, he was remarkable. His writings include nine or ten dramatic pieces, *Panacea, or a Poem on Tea*, various birthday odes, and an elegy on the death of Queen Mary. He lived to write the first birthday ode for George I. But T. is best known by the metrical version of the Psalms, which he executed in conjunction with Dr. Nicholas Brady, chaplain to King William and Queen Mary, which was attached to the Prayer-book, and came into general use in the Church of England, supplanting the older version made in the reign of Edward VI. by Sternhold and Hopkins.

TATIAN, one of the early apologists of Christianity against the pagan philosophers, and the founder of a sect which, whether under his own name, or under various other appellations derived from its peculiar tenets or practices, attracted considerable notice in the primitive ages. T. was born in Syria or Assyria about the year 130. Having cultivated rhetoric and philosophy in various places, he came to Rome about 162, where he became the disciple and friend of Justin the Martyr, and was by him converted to Christianity. He is known to have written many works, of which, however, only the Apology is preserved. The date of its composition is uncertain, but it was probably before the death of Justin in 166 A.D. T.'s famous *Diatessaron*, the earliest attempt at a complete Harmony of the Gospels, was one of the lost works. No trace appears in the Apology of the heterodox opinions of T., and it is alleged by Tertullian that it was not till after the death of Justin that he fell into the errors to which he has given a name. He then removed to the east, and is said to have established himself in Mesopotamia. Without entering into the details of T.'s peculiar opinions, it will be enough to say that, especially in their moral aspect, they form the foundation of one of the great divisions of Gnosticism (q. v.). Starting from the common principle of dualism, and of the origin of matter from the evil principle, and its consequent evil nature, T., unlike the Egyptian Gnostics, held the necessity of overcoming the corrupt nature of man, and purifying it by abstinence and ascetic rigor. Accordingly, he reprobated marriage, and condemned all sensual indulgence. One of his 'opinions,' affirming the damnation of Adam, was peculiarly odious to the orthodox party. He condemned the use of wine so strongly as to forbid it even in the celebration of the Eucharist, in which his followers permitted only water to be used, whence they received the name of *Hydroparastatai* (from *hydor*, water, and *paristemi*, I present), and in Latin *Aquarii*. From their generally rigorous ascetism, they were called *Encratites* (from *engkratein* to keep continent). In their dogmatic views as to Docetism, the Demiurge, and Emanations, they differed little from other Gnostics of the Syrian school. See Gnostics, Manichæans, Mysticism.

TATIUS, Achilles, one of the later Alexandrine authors, of whose life absolutely nothing is known. He was formerly thought to have flourished during the 2d or 3d c. A.D.; but as he undoubtedly imitated the style of Heliodorus of Emesa, he cannot be placed earlier than the beginning of the 6th c. (see Novels). Suidas, who calls him Achilles Statius, says that he was originally a pagan, but that he was afterwards converted to Christianity, and rose to be a bishop. If this be true, the romance which has preserved the author's name, *Ta Kata Leukippen kai Kleitophonta* (The Loves of Leucippe and Cleitophon), must have been composed before his conversion, for it is in parts too licentious and too heathenish to be the work of a Christian convert.

TA'TTA (more correctly, **Thatta**), a town of Sinde, on the right bank of the Indus, and at the head of the delta of that river, 64 miles east of Kurrachi. In former times, T. was a most flourishing town, and manufactured fabrics of silk and cotton. The mosque of Shah-Jehan, built of brick, is now falling into decay. The vast cemetery of T. has an area of 6 sq. m., contains, it is calculated, at least a million tombs, and has room for not less than four millions. Pop. of T. about 10,000.

TATTERSALL'S, a celebrated mart for the sale of horses in London, so called from Richard Tattersall, who died in 1795, and who was groom to the second Duke of Kingston. It was established near Hyde Park Corner in 1766, and, on the expiry of a 99 years' lease, in new premises at Brompton, April 1865. The racing subscription-room here is one of the principal rendezvous for patrons of the turf.

TATTOO, in Military life, is the beat of drum and bugle-call sounded at sunset to draw in all stragglers and others on detached duty.

TATTOO'ING, a custom extensively prevalent among savage nations, of marking the skin with figures of various kinds, by means of slight incisions or punctures and a coloring matter. The term is of Polynesian origin, and is said to be derived from a verb *ta*, which signifies to strike. Tattooing is almost universal in the South Sea Islands, except where Christianity and civilization have put an end to it. New Zealanders' heads, exhibiting tattooing, are amongst the curiosities to be seen in museums; and at one time it was very common for the masters of vessels visiting New Zealand to purchase them and bring them home, although there is too much reason to believe that the price paid for them stimulated the feuds of the natives. The tattooing of the New Zealanders and other South Sea Islanders often covers the whole face, and sometimes also the chest, arms, and other parts of the body with elaborate patterns. It is performed in youth, and marks the transition from boyhood to manhood, like the assumption of the *toga virilis* among the ancient Romans. The operation is accompanied with superstitious ceremonies, and is attended with considerable pain, which, of course, is to be endured with manly indifference. An instrument of bone, toothed on the edge, is employed, which is applied to the skin, and stuck with a piece of wood, having first been dipped in a thick mixture made by rubbing down charcoal with a little water. The marks which result are permanent, and appear black on a brown skin; although they are dark blue on the skin of a European. Tattooing is, or has been, practised in almost all parts of the world. It seems to be one of the practises prohibited to the Jews, in Lev. xix. 28, 'Ye shall not make any cuttings in your flesh for the dead, *nor print any marks upon you*,' from which may be inferred its prevalence among the surrounding tribes in the days of Moses, and its connection with their superstitions. The Bedouin Arabs, the Tunguses, and other eastern tribes, and many tribes of American Indians, practise it at the present day. Among the Bedouins, it is a favorite mode of female adornment. It prevailed among the ancient Thracians, and was distinctive of high rank. The ancient Britons also practised it, and traces of it appear to have lingered in England till after the Norman Conquest. Perhaps the practise of sailors to print anchors and other marks on their arms, may be regarded as a relic of it still subsisting.

New Zealand Chief's face tattooed.
(From a Photograph.)

TAU, Cross, in Heraldry, a cross of a form somewhat resembling the Greek letter *Tau*. St. Anthony is generally represented with a cross of this description, embroidered on the left side of his garment

TAUCHNITZ, Karl Christoph Traug, a famous German printer and bookseller, was born at Grosspardau, near Leipzig, in 1761. Bred a printer, he began, in 1796, a small printing business of his own in Leipzig, with which he shortly after conjoined publishing and typefounding, and which, in process of time, became one of the greatest establishments of the kind in Germany. In 1809, he began the issue of a series of editions of the classic authors, the elegance and cheapness of which gave them a European circulation. By offering a prize of a ducat for every error pointed out, he was able to bring out, in 1828, an edition of Homer of extraordinary correctness. He was the first to introduce (1816) stereotyping into Germany; and he also applied it to music, which had not been attempted before. In the latter years of his busy life, he stereotyped the Hebrew Bible, and the Koran in the original Arabic. On his death, in 1836, the business was continued by his son, Karl Christian Phil. Tauchnitz.—A nephew of the elder T., Christian Bernh. Tauchnitz, also set up a publishing establishment in Leipzig, combined with

printing. Among the most noted of his undertakings is the well-known issue of 'British Authors' (begun 1842), of which upwards of 2000 vols. have appeared. Ennobled in 1860, T. was made one of the few Saxon life-peers in 1877.

TAULER, JOHN, a remarkable mystic and preacher, was born at Strasburg in 1290, and died there 16th June 1361. About the year 1308, renouncing a considerable fortune, he entered into the mendicant order of Dominicans, and afterwards studied theology in Paris, showing at that early period a predilection for speculative and mystic writings, as the scholastic philosophy and the prevailing theology of the schools did not satisfy him. Notwithstanding this tendency, his predominating practical turn of mind led him, on his return to Strasburg, to preaching and pastoral duty; and this he continued to practice with zeal and undaunted courage, even when, in consequence of the excommunication which the pope had hurled against the Emperor Ludwig, the country had fallen into a state of dreadful distraction, and almost all the clergy, in obedience to the interdict issued by the Bishop of Strasburg, had suspended worship. Although T. was now 50 years old, and had enjoyed celebrity for several years as a preacher, so powerfully was he influenced by a Waldensian of the name of Nicholas von Basel, who paid him a visit in 1340, that he gave himself up for two years to ascetic exercises and devout contemplation. Afterwards, however, he betook himself more decidedly to vigorous exertions on behalf of the despised and oppressed people, and preached with wonderful power, inveighing against the avarice, ostentation, and hard-heartedness of the laity as well as of the clergy; and, although not departing from the doctrines of the church, yet fearlessly exposing its abuses, and even not sparing the pope. Thus it happened, that although he had indefatigably administered the consolations of religion in the midst of the horrors and desolation of the Black Death (q. v.), the bishop interdicted him from preaching, and he was obliged to quit his native town. He repaired to Cologne; but nothing further is known, either of his residence there or of his return to Strasburg, where, after a life full of toil, denial of self, and beneficence to others, he died, an old man of 70 years, and was buried in his cloister.

If not the greatest German preacher of the middle ages as a whole, T. certainly was the greatest of his times. As his mysticism was in no ways passive, but aimed at rising above the sad condition of his times and the failings of the church by inward piety and a love self-denying but at the same time active; so his style, both in his preaching and in his devotional works, was lively, impressive, picturesque, and had altogether a practical direction. Among his devotional works, the *Nachfolge des armen Lebens Christi* holds the first place. Whether the sacred hymns which bear his name really belong to him, is doubtful. Of his writings and sermons, in which he always used the German language, many have been preserved in MS.; and since 1498, numerous editions have been published, but untrustworthy, and often translated into the dialect of the place where they happened to be printed. A careful translation into new High-German has been published by Schlosser (*Predigten*, 3 vols. Frank. 1826; *Nachfolgung des armen Lebens Christi* (Frank. 1833); Schmidt, *Johannes Tauler von Strasburg* (Hamb. 1841); and Susannah Winkworth, *Life and Times of Tauler*, with 25 of his sermons translated from the German (Lond. and New York, 1857).

TAU'NTON (*Tone-ton*), so named from being built on the banks of the river Tone, is situated in the extensive and beautiful valley of Taunton Dean, or vale of Taunton, in the county of Somerset, 44 miles south-west of Bristol by railway. It communicates by railway with the Bristol and English channels. The streets are wide, well-paved, and lighted; the shops are modern and capacious, but the woollen and silk factories which were once extensive here have almost wholly departed. Assizes are held here twice yearly.

T. is the headquarters of the Somerset Archæological and Natural History Society, in connection with which there is an extensive museum, placed in the ruins of the Norman castle—rich especially in fossils from the Devonian strata, and the bones of mammalia of the cave period from Mendip and the Somersetshire gravels—and a well-conducted reading-room. There is a collegiate school founded by Bishop Fox, 1522, two dissenting colleges, several other good schools, and many charitable and other institutions. T., which is a parliamentary borough, returns two members to the House of Commons. Pop. (1881) 16,611. Ina, king of the West Saxons, built a castle in T. about 700 A.D. This was soon after destroyed, but another fortress was built on the site soon after the Conquest, at which period the town had a mint. In 1127, Giffard, bishop of Winchester, built and endowed a priory for the canons of St. Augustine; and in 1322, we find a house of Carmelite friars. The church of St. Mary is a magnificent specimen of Perpendicular architecture, and is famous for its graceful and delicately ornamented tower. That of St. James was the conventual church of T. Priory. The Shire Hall and the Literary Institution are handsome modern buildings. To T. Castle, Perkin Warbeck fled when he failed in storming Exeter. During the civil wars between Charles and the parliament, the town was twice besieged by Goring, and twice successfully defended by Colonel Blake. In T., Monmouth received the heartiest welcome, and Judge Jeffreys exercised his unbounded cruelty.

TAUNTON, a flourishing city of Bristol county, Massachusetts, U. S., on Taunton River, 35 miles south of Boston, and 30 miles E.N.E. of Providence. The falls of Taunton River and its branches furnish water-power to numerous factories, among which are 6 cotton-mills, 7 for machinery, 2 for locomotives, 6 foundries, 2 tacks and brads, copper and zinc, 2 Britannia ware; iron, metallic gas-pipes, enamelled cloth, screws, files, arms, crucibles, firebrick, &c. In copper manufacture, a capital of about £180,000 is invested; in making iron, which is the chief manufacture, about £400,000. Pop. (1880) 21,213. Several railways pass through T., and it has also a considerable coasting-trade, and important fisheries of shad, herrings, and alewives. There are 19 churches, 60 schools, a state hospital for the insane with 400 patients, academy, court-house, 1 daily and three weekly newspapers, 3 banks, &c. T. was settled from Taunton in England in 1638. Its first minister was William Hooke, afterwards a chaplain of Cromwell.

TAU'NUS MOUNTAINS. See NASSAU.

TAU'RIDA, a government of South Russia, bounded on the E., S., and S.-W. by the Sea of Azov and the Black Sea. Area, 24,140 sq. m.; pop. 878,925, mostly Nogai Tartars. The peninsula of the Crimea (q. v.) forms the southern portion of the government, and is connected with the northern portion by the Isthmus of Perekop (q. v.). The region north of the isthmus is flat; the Crimea contains mountain-ranges which rise upwards of 5000 feet. The only great river is the Dnieper, which forms the north-west boundary; and the other principal streams are the Salgir and Alma in the Crimea. Among the salt lakes of the Crimea, which are very productive in salt, the Lake of Sakky is celebrated for the efficacy of its waters in certain cases of disease. The climate is temperate and warm on the southern shores of the Crimea. The soil is fertile, but cultivation is carried on on a very limited scale. In the north, the pasturage is very rich, and cattle-breeding is the main employment of the inhabitants. In the south, the mountains are clad with forests, the tobacco-plant is successfully cultivated, and fruit-growing and wine-culture are the principal occupations. The Crimean wines, the *bouquet* of which resembles that of Burgundy and the Rhenish wines, are of a very good quality. The native riches of the government, its excellent ports and harbors, promise great commercial progress. Simferopol (q. v.), in the Crimea, is the capital of the government, and Sebastopol (q. v.) and Theodosia are ports of rapidly increasing importance.

TAU'RINE, $C_4H_7NO_3S_2$, is a very remarkable substance occurring in the bile and in other animal products and tissues. In a state of purity, it forms six-sided glistening prisms, which are perfectly transparent, neutral, devoid of odor, readily soluble in hot water, but difficult of solution in cold water, and insoluble in alcohol and ether. It does not enter into combination either with acids or bases. When heated, it undergoes decomposition, and evolves sulphurous acid, in consequence of the sulphur (upwards of 25 per cent.) which it contains. Taurine occurs naturally in the bile of many animals, including man. As a product of the decomposition of the bile, it may be found in the contents of the intestine and in the excrements; and in cases of jaundice it has been found in the blood, transudations, and urine. Its artificial formation has been noticed in the article SYNTHESIS. Its name is derived from the Latin *taurus*, a bull, because taurine was first discovered in the bile of the ox.

TAU'RUS, MOUNT. See ANATOLIA.

TAUTO'G, or BLACKFISH (*Tautoga nigra* or *Americana*), a fish of the family *Labridæ* (q. v.), of the section forming the family *Cyclo-labridæ* of Müller. It is found in the North American seas, and is in great request for the table. It brings a very high price in the New York market. It attains a size of 12 or 14 lbs. Its color is black on the back and sides; the belly is whitish; both jaws have a double row of strong conical teeth; the face is covered with a scaleless integument. The T. is caught by hook and line on rocky bottoms. It is sometimes kept in stews to fatten.

TAUTO'LOGY (Gr. *tauto*, the same, and *logia*, speech) is a term used to denote the useless repetition of the same ideas in different words. It is considered one of the worst vices, whether of oral or written style, and certainly none more effectually robs language of its force and impressiveness.

TA'VERN, a place of entertainment for man and beast, is not a legal term. See INN, PUBLIC HOUSES.

TAVERNIER, JEAN BAPTISTE, BARON D'AUBONNE, a celebrated French traveler, was the son of a Flemish engraver who had settled in Paris, and was born there in 1605. The conversa-

tion of the savants who frequented his father's shop inspired him with an ardent curiosity to visit other countries, and prompted him to leave the parental roof before his 15th year. After visiting England, the Low Countries, Germany, Hungary, and Italy, he eagerly caught at the offer made to him by Father Joseph (the confidant of Richelieu), to accompany two French noblemen to the East. This journey lasted from December 1630 to the summer of 1633, the line of route passing through Regensburg, Dresden, Vienna, Constantinople (where he left his masters), Erzeroum, Tabriz, Ispahan, Bagdad, Aleppo, and Scanderoon, and thence by sea to Rome. T. then obtained an important post in the household of the Duke of Orleans, but received occasional leaves of absence to prosecute his journeys in the East.

The *second journey* (1638—1643) was from Marseille to Scanderoon, thence across Syria to Ispahan, South-western Persia, and Hindustan; the *third* (1643—1649), through Ispahan, much of Hindustan, Batavia, and others of the East Indies; and in the *fourth* (1651—1655), *fifth* (1656—?), and *sixth* (1663—1669), various portions of Persia and Hindustan were visited, the outward route being generally by way of Syria and the Arabian Desert, and the return one by Asia Minor. T. invariably traveled as a dealer in precious stones and other valuable articles of small bulk, and the great profits he realized strongly impressed upon him the advantages of regular commerce between Europe and the East. On his return to France in 1669, he was graciously received at court by Louis XIV., who presented him with 'letters of nobility' in reward for his services to French commerce in India. But his prodigal expenditure and careless generosity speedily reduced his fortune, and the revocation of the Edict of Nantes compelled him to take refuge in Switzerland, whence he removed to Berlin, and became director of an East India Company which was projected by the Elector of Brandenburg. With the view of discovering a road to the Indies through Russia, he set out from Berlin in 1688, but died at Moscow in July 1689. An account of his travels was written for him by various parties (for T. had no literary qualifications), and though full of matter valuable to the historian and geographer, it is so ill-arranged as to be in many cases almost unavailable.

T. was one of the most remarkable of travelers; wholly devoid of classic sentiment, he traversed the plains of Troy, and passed the ruins of Persepolis without even a flutter of interest, and partly owing to this remarkable condition of mind, his statements are distinguished by an accurate truthfulness little common among travelers. But the chief value of his book lies in the fulness and accuracy with which the nature and state of oriental commerce, the chief markets and commercial routes, and the various systems of coinage and their relations are detailed. Some of his statements concerning the conduct of the Dutch in the East Indies called forth a most virulent and abusive reply from Jurieu, the Protestant theologian, in his *L'Esprit de M. Arnauld* (1684), and a more moderate one from Van Quellenburgh; but all T.'s assertions which were of any moment were found to be perfectly correct. His Travels were originally published in 3 vols. (two in 1676—1677, and the third in 1679); they have since been several times republished, last in 1810, in 7 vols.; and have been translated into English (1678, 1684, 2 vols.), Dutch (1682), and German (1684).

TAVI'RA, a seaport town of Portugal, province of Algarve, 20 m. N.-E. of Faros, pleasantly situated at the mouth of the Sequa. T. has decayed considerably since 1654, when, it is said, 40,000 people in the town and environs fell victims to the plague. Pop. (1878) 11,636.

TA'VISTOCK, a parliamentary borough and market-town of Devonshire, picturesquely situated on the western border of Dartmoor, about 35 miles south-west of Exeter, in the fertile valley, and on the right bank, of the Tavy (whence its name), which is here crossed by two bridges within the town. T. is a thriving town, with some small manufactures of serges and woollen cloths, iron-foundries and mining-works, copper, lead, tin, and iron being found in considerable quantity in the neighborhood; but the population is chiefly agricultural. It is a place of considerable antiquity, and was formerly of great importance, owing mainly to its abbey, the largest and most magnificent in Devonshire, which was founded in the year 961, for the Benedictine order, by Ordgar, Earl of Devonshire, father of the infamous Elfrida, and endowed with many privileges, the abbot being a peer of parliament. At the dissolution, when the revenue amounted to upwards of £900, it was bestowed upon John, Lord Russell, in possession of whose descendant, the Duke of Bedford, the property still remains. A printing-press, the second set up in England, was established in the abbey at a very early period. The refectory and abbey gateway still exist in good preservation. The parish church is a handsome edifice, with a tower at the west end, resting on arches, under which there is a thoroughfare. The borough sends one member to the House of Commons. At the breaking out of the Civil War, Pym was member for Tavistock. T. is one of the four stannary towns of the county, and is governed by a port-reeve, elected annually; a county court is held in the town. It is connected with Barnstaple, Launceston, and Plymouth by railway, and with the river Tamar by a short canal. Sir Francis Drake was born in the immediate neighborhood in 1545, and the poet W. Browne in the town in 1590. Pop. (1871) of parliamentary borough, 7725; (1881) 6909.

TAVOY', the chief town of a district in Tenasserim, British Burmah, is situated on the left bank of the Tavoy River, about 30 m. from its mouth, at the distance of about 220 miles south of Moulmein. The site of T., which is low, is enclosed on three sides by rice-fields, and on the fourth by the river. The houses are scarcely visible from the river—umbrageous trees, palms, plantains, jacks, cassias, and hundreds of flowering shrubs, nearly concealing them from view. A wooden-covered pier, supported on piles, forms a convenient landing-place. There is a hospital, a large jail, and a roomy *zayat* or caravansary. The houses are raised from the ground on piles, and are made of bamboo, fastened with rattan, and thatched with the leaf of the water-palm. T. is remarkable for its grand annual buffalo-fight. The sport continues for two days, and during that time eight pair of buffaloes are brought into the field, each animal representing a different district or township. The rice-fields around T. are prolific sources of malaria. Intermittent fevers and dysentery are the most common diseases; but the climate is on the whole healthy. Pop. of T. (1872) 14,467. The bulk of these are true Burmans, the balance being made up with Shans and Thoungthoos, Karens, Chinese, Malays, and natives of India. T. exports rice, sugar, wood-oil, timber, and fruits. The anchorage for large ships is at Goodridge Plains, about 30 miles below the town.—The district of T. has an area of 7200 square miles, and a pop. (1872) of 71,827.

TAX, TAXATION. The proportion in which the various taxes contribute to the revenue of the United Kingdom may be ascertained from the article REVENUE. Distinct from imperial taxation is *local* taxation, locally raised and administered, under the superintendence of the Local Government Board, which was established and first published returns of local taxation in 1870–71. In that year the total amount of local taxation, including rates, tolls and dues, and duties, but excluding money raised by loans, was £21,580,000; in 1879–80 it was £31,043,100. In 1879–80 there was obtained besides £22,879,651, from 'other sources' than taxation, mainly from loans, with a few government grants. The entire local revenue was therefore £53,940,751, to cover a local expenditure of £50,253,007.

The term taxation, as expressing the exaction of money from the individual for the service of the state, is familiar to all mankind a step above barbarism; and yet few subjects are surrounded by a greater number of practical difficulties and theoretical niceties. These may be grouped under two sets of considerations—those which affect the justice of a tax, and those which affect its productiveness, and these two often tell on each other. Taxation, indeed, has so frequently been the means of perpetrating political injustice, that the term has fallen into bad popular repute. Whenever the produce of a tax is used otherwise than in the service of those who pay it, the tax is unjust. In its more oppressive form, it has been levied on conquered states, for the benefit of the conquerors, and in this shape it has sometimes been called tribute. The direction which all constitutional struggles to cleanse taxation from injustice have taken has been that of self-taxation, the community as a whole deciding on what it requires to take from the individual members for the public service. The accomplishment of this has been the chief object of all the struggles which have made a free constitution for the British Empire. There were old feudal dues which the monarchs had the power of exacting; but when these were insufficient for their ambitious projects, they had to ask parliament for a supply, and parliament generally took the opportunity of granting it to demand redress of grievances. It came thus to be a fundamental constitutional doctrine, that no tax can be levied save by the consent of the representatives of the people who have to pay it. The constitutional doctrine thus created by Britain was remembered by the American colonies when Mr. Grenville sought to raise there a stamp-duty and a customs-duty on tea, and the colonies revolted under the celebrated cry that 'Taxation without representation is tyranny!'

It was discovered, in the course of the long struggle of the House of Commons to keep its hold on the purse, that the least afflictive of taxes may be the most dangerous. A fixed land-tax comes, for instance, to be no impost at all, in the afflictive sense of the term. If a thousand a year has been drawn off a certain acreage of land from time immemorial, the proprietors never possessed that part of the rents, and are no more sufferers from not having them than from not possessing their neighbors' estates. A government with a large revenue of this kind, however, will certainly be inimical to freedom. The time when the liberties of England were in the greatest danger was the twelve years of

Charles I.'s reign in which he was able to get on without going to parliament for money. The extravagance of sovereigns who wasted the domains of the crown has generally prevented them from having too formidable an influence by the possession of independent incomes. In Britain, this difficulty has been effectually guarded against, and any of the expenses of the crown which can now be paid without going annually to parliament for a vote of supply are of a very trifling character.

How to make taxation productive, is a vast and complicated practical science. Turgot, one of the wisest of financiers, called it the art of plucking the goose without making it cry. The most ingenious devices to this end, however, have often, in practice, met with counteracting difficulties. It was supposed that indirect taxation—that is, a duty levied on articles before they reach the consumer, must, in a civilized and orderly country, be almost inexhaustible. The merit of the system lay in the consideration, that the burden of the tax did not fall on the person who paid it. Income-tax, house-tax, dog-tax, and the like are levied directly on the person on whom the burden ultimately falls, and if he do not pay, the amount will be taken by force.

Tea-duty, wine-duty, and the like, however, are not levied on the consumer, though he was to pay them; they are levied on the importer, who has no, or a very slight, interest against the tax, since he must charge it on the consumer. But this form of taxation is met by checks. If it is excessive, people will not buy the taxed article; and it has often been found that reducing the duty increases the revenue. An indirect tax on luxuries, and especially on those which may be used to vicious excess, has strong recommendations. In some cases, it is no great calamity should the tax throw the article nearly out of use. But then comes another check in the smuggler, whose profession may probably do more to corrupt and disorganize society than the free use of the article in which he deals. A tax on the necessaries of life, on bread or salt, cannot be evaded, as in the case of luxuries, by the abandonment of use, and therefore it is very productive, but it is also very oppressive. The tax on salt in France was one of the chief causes of the French Revolution. The happiest condition for the revenues of a country is when luxuries are so abundantly used by all classes that a small addition to their price is a slight burden, yet yields a large revenue. In this country, the revenue thus derived from tea, tobacco, and stimulants may be set down in round numbers at 30 millions. The chief taxes which now form the revenue of Britain are—1. Those by old custom called 'assessed,' and levied upon certain items in the possessions and enjoyments of the citizen, as his male-servants, dogs, carriages, and armorial bearings. 2. The property and income tax, which, after long disuse, was renewed in 1842, and is raised from time to time according to the exigences of the government. 3. The customs. 4. The excise. 5. The stamps and post-office; and 6. The land-tax See CUSTOMS DUTIES, EXCISE, POST-OFFICE, STAMPS, LAND-TAX, FINANCE.

TAXA'TION OF COSTS is the checking or reviewing of the charges made by attorneys or solicitors for legal business; and there is an officer of the court provided for the purpose, called in England a master or a taxing-master, or a registrar, according to the nature of the court; in Scotland, he is called an auditor. Solicitors differ from all other professions in this, that they are treated as officers of the court, and they are not at liberty to charge what prices they please for the various services they perform. Hence, every step in a suit has a certain value put upon it by the court, and the business of the taxing-officers is to see that this standard is not transgressed. There are many exceptional matters, however, which arise in every suit, which often cause difficulty in apportioning a proper amount of remuneration, the taxing-officer having a considerable discretion. In consequence of a taxing-officer being provided by the court, it is a right which every client of a solicitor has, if not satisfied with the bill of costs delivered to him, to have it referred to the taxing-officer to be taxed. But in general, this must be done without delay. If the taxing-officer certify that more than one-sixth too much has been charged, then not only is the client not bound to pay the excess, but the expense of the taxation must be borne also by the solicitor; whereas if less than one-sixth is taxed off, the client has to bear the expense of taxation. Not only are the expenses of a suit liable to taxation, but other kinds of miscellaneous business which a solicitor does as a solicitor. It has often of late been made matter of complaint that solicitors are not allowed to fix their own charges, or to agree with clients upon an arbitrary charge, or a charge by commission, the tendency of the present system being to make the solicitor anxious to eke out his remuneration by lengthening the proceedings, so as to make a basis for chargeable items; but the legislature has steadily rejected hitherto all attempts to abolish the check provided by taxation.

TAXEL. See BADGER.

TAXICO'RNÉS, a family of coleopterous insects, of the section *Heteromera*, having the body generally square; the thorax either concealing or receiving the head; the antennæ short; the legs adapted for running. Most of them are found in fungi and beneath the bark of trees. They are widely distributed over the world.

TA'XIDERMY, the art of preparing the skins of animals for the purposes of the naturalist. The chief means employed in preparing the skin for stuffing in the case of small animals is to remove it carefully from the body, and, having cleaned away from it any adherent flesh, &c., to anoint it with arsenical soap; for the making of which there are several formulæ, the following being the most used: arsenic, 1 ounce; white soap, 1 ounce; carbonate of potash, 1 drachm; distilled water, 6 drachms; camphor, 2 drachms. This keeps the skin supple, and prevents decay and the attacks of insects. The larger skins are generally prepared with a composition called Preservation Powder, which is made of the following ingredients: Arsenic and burnt alum, each 1 lb.; powdered oak-bark, 2 lbs.; camphor, ½ lb. These substances are all reduced to a powder, mixed, and passed through a fine sieve. It requires to be carefully kept in well-stoppered bottles or jars, and when used, is thickly sprinkled over the flesh-side of the skin whilst still wet, and must be thoroughly rubbed in. Gloves should always be worn in this process, to prevent danger from the poisonous compound. Some skins are prepared with alum only, and others with the oak-bark liquor of the tanner's pits. This, in the case of very large skins, answers very well.—Besides the mere preparation of the skin, the art of taxidermy is held to mean also the stuffing and mounting of them. This requires much personal experience, and as almost every group of animals must be treated differently, it is impossible to explain the various methods fully in this short notice. Various works have been written upon the subject.

TAY, the largest river in Scotland, draining nearly the whole of Perthshire (q. v.), and pouring into the German Ocean a greater bulk of water than any other British river, has its source in the western part of the county of Perth. The Dochart, the principal feeder of Loch Tay, rises in Ben Lui, on the borders of Argyleshire, and flowing in a north-east direction, is joined by the Lochy, just before the united streams enter the lake. After leaving it, the Tay flows for some distance east-north-east, when turning southwards, it passes, with a very winding course, Dunkeld (q. v.) and Perth (q. v.); about a mile below the latter place, it again changes its direction to east-north-east, widening at the mouth of the Earn (q. v.) into an estuary—the Firth of Tay—which varies from three-fourths of a mile to three miles in breadth, and lies mostly between the counties of Fife and Forfar, joining the German Ocean about ten miles below Dundee (q. v.). From the north and east, the Tay receives the Lyon, the Tummel and Garry, and the Isia; and from the west, the Almond and the Earn; its entire basin comprises an area of about 2500 square miles. The salmon-fishings on the Tay and its tributaries are of considerable value. The Stormontfield ponds for the propagation of salmon are 5 miles above Perth. The tide flows up the river to about a mile above Perth; but the navigation up to Dundee is attended with very great difficulty on account of the numerous and shifting sand-banks. The railway bridge which spanned the estuary, near Dundee, at a point about two miles wide, was destroyed during a violent gale of wind in 1879.

LOCH TAY is a long and narrow lake, picturesquely situated in a basin scooped out of the bosom of the mountains, 355 feet above the sea-level, in length about 15 miles, and average breadth 1 mile, varying from 100 to 600 feet in depth. Ben Lawers (q. v.) lies on its west side. The loch is at times subject to violent and unaccountable agitations.

TAYLOR, BAYARD, an American author and traveler, born at Kennett Square, Chester County, Pennsylvania, January 11, 1825. Having received a common school education, he was apprenticed at 17 in a printing office, when he began his poetical contributions to periodicals. In 1844 he published a volume of poems under the title of *Ximena*, and soon after, started on a pedestrian tour of Europe, and in 1846 published *Views Afoot, or Europe seen with a Knapsack and Staff*. After his return, he edited a country newspaper, then went to New York, and wrote for the *Literary World* and *Tribune*. Of the latter, he became assistant-editor, and as its correspondent, made extensive travels in California and Mexico, recorded in *El Dorado*, or *Adventures in the Path of Empire*, 1850; up the Nile to lat. 12° 30′ N., and in Asia Minor, Syria, across Asia to India, China, and Japan—recorded in his *Journey to Central Africa, Lands of the Saracen*, and *Visit to India, China, Loo-Choo, and Japan* (1853). Later explorations are recorded in *Northern Travel, or Summer and Winter Pictures of Sweden, Denmark, and Lapland* (1856); and *Travels in Greece and Russia, with an Excursion to Crete* (1857). In 1862—1863 he was connected with the embassy at St. Petersburg; and in 1874 he visited Iceland. He resided some years in Germany, and in 1878 was appointed United States ambassador at Berlin, where he died in December 1878. In 1848, he published *Rhimes of Travel, Ballads and other Poems*:

Book of Romances, Lyrics, and Songs (1851); *Poems of the Orient* (1854); *Poems of Home and Travel* (1855); *At Home and Abroad* (1859—1862); *Hannah Thurston*, a novel (1864); *Beauty and the Beast*, and *The Masque of the Gods* (1872); *The Prophet, a Tragedy* (1874); *Home Pastorals*, &c. (1875); *Prince Deukalion*, a drama (1878). He translated *Faust* in 1871, and for the last twelve years of his life was engaged upon a life of Goethe.

TAYLOR, Brook, a celebrated English mathematician, was born at Edmonton, in Middlesex, August 18, 1685, of a Puritan family of good position, entered St. John's College, Cambridge, in 1701, at a time when mathematical science was the prominent pursuit among the learned, took his degree of LL.B. in 1709, became a Fellow of the Royal Society in 1712, and its secretary in 1714, in which latter year he also took the degree of LL.D. Though so young, he had become widely known in Britain and on the continent for great proficiency in mathematical knowledge, and power and versatility of mind, having already written various valuable treatises on capillary action, on the vibration of a string, on music, &c. In 1716, he visited Paris, and was received with warm demonstrations of regard by the French savans, who respected his ability and learning, and the prominent and distinguished part he had taken in the Leibnitzian controversy. On his return to England in 1717, he resumed his habits of severe study, but was forced by declining health to resign the secretaryship in 1718. For the next three years he wandered about, residing now on the continent, now in England. He died, December 29, 1731, at the age of 46. Besides his earlier works above mentioned, he contributed a series of able papers on higher algebra, dynamics, and general physics, published separately his *Methodus Incrementorum* in 1715, and a *Treatise on Linear Perspective*, the first general exposition of this subject, in 1719. During the last ten years of his life, he gave himself up almost entirely to metaphysical and biblical studies. His *Methodus Incrementorum* contains, besides the famous 'theorem' (see Taylor's Theorem), the first germs of the calculus of finite differences, various now common forms of infinitesimal series, with mechanical, physical, and algebraical applications. The chief use made by T. of his theorem is in a paper (1717) entitled 'Method of Approximation to the Roots of Equations.' The results of his investigations may be found in the *Phil. Trans.* (1713—1723), and in his two works above mentioned.

TAYLOR, Isaac, born at Lavenham, in Suffolk, 1787, died at Stanford Rivers, in Essex, 1865, eminent as a Christian philosopher, artist, and mechanician, was the third of his name who attained distinction—his grandfather and father (known as Isaac Taylor of Ongar) being both named Isaac, and each in his way distinguished. Charles Taylor, the editor of *Calmet*, was an uncle, and Jane Taylor (author of the *Q. Q. Papers*) and Ann Taylor (Mrs. Gilbert of Nottingham), joint authors of *Hymns for Infant Minds*, were sisters, of the subject of this article. The literary career of Isaac T. extended over nearly half a century. It began in 1818, in contributions to the *Eclectic Review*, for which Robert Hall, John Foster, and Josiah Conder then wrote, and ended in 1865, in contributions to *Good Words*, in which the name of the veteran figured with those of men who were unborn when he was in the height of his reputation. Between 1822 and 1827, he published *Elements of Thought; Characters of Theophrastus*, with illustrations etched by himself; *The History of the Transmission of Ancient Books to Modern Times. The Process of Historical Proof*, a translation of Herodotus, and the *Memoirs and Correspondence of Jane Taylor*, his sister, who has already been mentioned. In 1829, he published anonymously, *The Natural History of Enthusiasm*, which ran rapidly through several editions; and between 1829 and 1836, he published in succession *Fanaticism, Spiritual Despotism, Saturday Evening*, and *The Physical Theory of Another Life*. In 1836, appeared *Home Education*. Thereafter, he was a long time occupied upon a new translation of Josephus, undertaken jointly with the Rev. Dr. Traill, and which was illustrated by etchings executed by himself. Within the last thirteen years of his life appeared *Loyola, Wesley, The Restoration of Belief, Logic of Theology, Ultimate Civilization*, and *The Spirit of Hebrew Poetry*. Besides these numerous works, Isaac T. wrote many articles for the graver quarterly reviews, which are as yet uncollected. He had been educated as an artist, and some of his designs, executed before he betook himself chiefly to literature, have evoked the warmest praise from the most scrupulous critics, who have wondered how one with such a genius for art could have deserted it. It would be impossible to give here any account that would be intelligible of his numerous mechanical inventions; it must suffice to say, that, by two of his inventions, he revolutionized the art of calico-printing. Isaac T. married in middle life, and had a large family, whose home education, as liberal-minded but pious Christians, was among, and not one of the least of, the tasks of his life.

TAYLOR, The Rev. Isaac, M.A., vicar of Holy Trinity, Twickenham, and eldest son of the preceding, was born at Stanford Rivers, March 3, 1829. He is the author of *The Liturgy and the Dissenters*, and one or two other theological pamphlets; but has best maintained the literary distinction of his family by his works on philology. His *Words and Places, or Etymological Illustrations of History, Ethnology, and Geography* (1864), of which a second edition, revised and enlarged, was published in 1865, is a work of great research as well as erudition, and has done more towards the elucidation of the local names of English places than any book yet published. In *Etruscan Researches* (1874), T. tries to prove that the Etrurians were allied to the Turkish or Mongolian races. This proposition, however, is not well established, and the work has received severe handling from critics, especially from Prof. Max Müller. In 1876 T. published *The Etruscan Language*.

TAYLOR, Jeremy, one of the greatest names in the English Church, was the son of a Cambridge barber, and was born in that town, August 15, 1613. At the age of 13, he entered Caius College as a sizar, and after seven years' strenuous and brilliant study in classics and theology, took the degree of M.A. Like Archbishop Usher, he was admitted to holy orders before he had reached his 21st year. Soon after he attracted the notice of Laud (who had a regard for learning, if none for liberty), and was preferred by him to a fellowship at All Souls, Oxford (1636). About the same time, he was appointed chaplain in ordinary to the king; and in 1638, rector of Uppingham, a preferment which he retained till the successes of the Parliamentarians deprived him of it. The first notable publication of T.'s was a defence of the church, entitled *Episcopacy asserted* (Oxford, 1642). It procured for him the honor of D.D.

During the next three years, T. probably accompanied the royal army; but when fortune had unmistakably declared against the king, he withdrew into Wales (1645—1646), and, in conjunction with Mr. W. Wyatt of St. John's College, Oxford, opened a school at Newton, in Caermarthenshire. It appears to have been a pretty successful adventure, and many of his scholars, we are told, 'having, as it were, received instruction from this prophet in the wilderness, were transplanted to the universities.' T. also found a patron in the Earl of Carbery, who was then living at the family seat of Golden Grove, in the same county, and who appointed him his domestic chaplain. But if this period of T.'s life had become to the outward eye obscure and mean, it is rendered illustrious by the splendor of his literary achievements. Between 1647 and 1660, the long 13 years of his enforced seclusion, appeared all his great works, and remembering their unsurpassed merits, we are almost disposed to feel grateful to those who expelled him from his rectory, and drove him to strictly literary pursuits. In 1647, was published the *Liberty of Prophesying*, a work written on behalf of the clergy of the Church of England, who were being expelled from their livings by the victorious Puritans, but in which the pleadings are based on principles far more comprehensive and tolerant than the age was disposed to acknowledge; in 1650, the *Life of Christ* (2 vols.), one of the most popular of his productions, and *The Rule and Exercises of Holy Living;* in 1651, *The Rule and Exercises of Holy Dying*, a portion of his *Sermons*, and the *Discourse of the Divine Institution, Necessity, and Sacredness of the Office Ministerial;* in 1652, a *Discourse on Baptism, its Institution, and Efficacy upon all Believers;* in 1653, 25 additional *Sermons;* in 1654, *The Real Presence and Spiritual of Christ in the Blessed Sacrament;* in 1655, *The Guide of Infant Devotion, or the Golden Grove*, and the *Unum Necessarium, or the Doctrine and Practice of Repentance*, a decidedly Pelagian treatise, which involved him in a considerable controversy; in 1657, a *Collection of Polemical and Moral Discourses*, a *Discourse on Friendship*, &c.; and in 1660, his famous *Ductor Dubitantium, or the Rule of Conscience in all her General Measures*, the most learned, subtle, and curious of all T.'s works. It was dedicated to Charles II. T. was a stanch royalist, a splendid scholar, a consummate theologian, and a man of wonderful literary genius, and so it was in the nature of things almost impossible that he should escape preferment.

Before 1660 had expired, he was elevated to the bishopric of Down and Connor, a dignity which he only retained some seven years, dying August 13, 1667. T. was not happy in his Irish see. Before a year was over, he was anxious to be delivered from it as from 'a place of torment.' The Scotch Presbyterian ministers were 'incendiaries'—they robbed him of the 'people's hearts;' they even 'threatened to murder' him; his only hope was in the government and the military. Altogether, it is a melancholy spectacle to behold the finest ecclesiastical genius of the time half broken-hearted by petty squabbles with intolerable fanatics, who had, nevertheless, in the points at issue between them and T., something like justice on their side. No modern mind would hesitate for an instant to acknowledge that the Scotch-Irish Presbyterian clergy were perfectly entitled to act as they did, and yet we fear it is too plain that the good bishop would have gladly seen them prohibited by an Episcopalian soldiery. Nay, the author of the *Liberty of Prophesying* went a step further; and on one occasion, only three months after his consecration, actually deposed 36 Presbyterian ministers occupying livings which the Restoration

had inconsiderately and tyrannically declared to be Episcopalian. Some very interesting information in regard to this all but unknown period of T.'s life is to be found in *Notes and Queries* (November 11, 1865).

T., sometimes styled the modern Chrysostom (q. v.), on account of his golden eloquence, has no equal in the whole series of ecclesiastical writers for richness of fancy. All other divines —patristic, medieval, and modern—show poor and meagre beside him in this respect. Some are more logical, or penetrating, or profound; some grasp more clearly the spiritual significance of doctrine, or display a deeper knowledge of human nature; but T. ranks among the first men of his age in point of learning, subtlety of argument, elevation of devout feeling, and philosophic largeness of view, while his inexhaustible imagery, shining 'like the glossy purples of a dove's neck,' and full of all tender and pathetic beauty, reminds us of Spenser and Shakspeare, of Sidney and Fletcher, rather than of the sombre order of theologians.—The best edition of T.'s works is by the Rev. C. P. Eden, M.A., Fellow of Oriel College, Oxford (10 vols., London, 1854).

TAYLOR, ZACHARY, twelfth President of the United States, was born in Orange County, Virginia, November 24, 1784, son of Colonel Richard Taylor, an officer of the War of Independence, and one of the first settlers of Louisville, Kentucky, where T. was taken in early childhood, and grew up to his 24th year, working on a plantation, with only the simplest rudiments of education. His elder brother had received a lieutenancy in the army, and died in 1808, when T. was appointed to the vacant commission. In 1810, he was promoted to a captaincy; and in 1812, with 50 men, two-thirds of whom were ill of fever, he defended Fort Harrison, on the Wabash, against a large force of Indians led by the famous chief Tecumseh. Promoted to the rank of major for his gallantry, he was employed during the war in fighting the Indian allies of Great Britain. In 1822, he built Fort Jesup; in 1832, he served as colonel in the Black Hawk War; and in 1836, was ordered to Florida, where he gained an important victory over the Seminole Indians at Okechobee, for which he was appointed brigadier-general, and made commander of the United States forces in Florida. In 1840, having been appointed to the command of the south-western department, he purchased an estate at Baton Rouge, Louisiana. On March 1, 1845, the United States Congress passed the resolution for the annexation of Texas, formerly a province of Mexico, and for some time an independent republic. Texas claimed the Rio Grande for her south-western boundary; Mexico insisted that there could be no claim beyond the Nueces, and prepared to defend the disputed, if she could not reconquer the whole, territory. General T. was ordered to Corpus Christi, which point he occupied in November with a force of 4000. On March 8, 1846, he moved towards the Rio Grande, across the disputed territory, and built Fort Brown, opposite and commanding the Mexican port of Matamoras. General Ampudia, the Mexican commander, demanded that he should retire beyond the Nueces, pending negotiations; and on the refusal of General T., his successor, General Arista, crossed the Rio Grande with a force of 6000. On May 8, he was defeated at Palo Alto by General T., with a force of 2300; and a few days after, driven from a new position at Resaca de la Palma across the Rio Grande.

War was declared by Congress to exist by the act of Mexico; 50,000 volunteers were called for, T. made major-general, reinforced, and ordered to invade Mexico. On September 9, with 6625 men, he attacked Monterey, which was defended by about 10,000 regular troops. After 10 days' siege and 3 days' hard fighting, it capitulated. General Scott having been ordered to advance on the city of Mexico by Vera Cruz, withdrew a portion of the troops of General T., leaving him only 5000 volunteers and 500 regulars, chiefly flying artillery, to meet an army of 21,000 commanded by President Santa Anna. He took a strong position at Buena Vista, fought a desperate battle, and won a decided victory. This victory, against enormous odds, created the utmost enthusiasm; and General T., popularly called 'Old Rough and Ready,' was nominated for President of the United States over Henry Clay, Daniel Webster, and General Scott; and this 'ignorant frontier colonel, who had not voted for forty years,' and was a slaveholder, was triumphantly elected, over General Cass, the democratic, and Martin Van Buren and Charles Francis Adams, free-soil candidates. Entering upon the presidency in 1849, he found a democratic majority in Congress, with a small but vigorous free-soil party holding the balance of power, while the most exciting questions connected with the extension of slavery, as the admission of California, the settlement of the boundaries of Texas, the organization of the newly-acquired Mexican territories, &c., were agitating the country, and threatening a disruption, postponed by the compromises introduced by Mr. Clay. Worn down by the unaccustomed turmoil of politics, the rough, good-natured old soldier did not long enjoy his honors. On July 4, 1850, sixteen months after his inauguration, he was attacked with bilious cholic, and died on the 9th.

TAYLOR'S THEOREM, so called from its discoverer, Dr. Brook Taylor (q. v.), is a general method for the algebraic development of a function of a quantity, x, in powers of its increment h, and may be thus briefly explained and illustrated. Let $f(x+h)$ denote *any* function of $x+h$ (subject to the limitations below), then $f(x+h) = f(x) + f'(x)\frac{h}{1}+f''(x)\frac{h^2}{1.2}+f'''(x)\frac{h^3}{1.2.3}+\ldots$, where $f(x)$ is the same function of x, as $f(x+h)$ is of $x+h$, and $f'(x), f''(x)$, &c., are the first, second, &c., differential coefficients of $f(x)$. By a supplementary theorem, due to Lagrange, who was the first to appreciate to the full the value of Taylor's discovery, it was shown that the sum of all the terms of the series after n terms, could be represented by $f^n(x+\theta h)\frac{h^n}{1.2\ldots n}\ldots$, where θ is some positive fraction less than unity. The theorem supposes that between certain limits indicated by $h=o$, and $h=$ some finite quantity, neither $f(x)$ nor any of its derived functions vanish, or all of them do not become infinite; and the cases in which these conditions are not satisfied are often spoken of as instances of the 'failure of Taylor's theorem.'

An important particular case of this theorem, known as *Maclaurin's*, or (more properly) *Stirling's Theorem*, was independently discovered; it is that case of the general theorem in which the various functions of x are made functions of zero, and is written $f(o+h) = f(o) + f'(o)h + f''(o)\frac{h^2}{1.2}+$, &c. The best illustrations of these theorems are the binomial, exponential, logarithmic, and circular series; thus, if the function be $(x+h)^n$, then $f(x) = x^n, f'(x) = nx^{n-1}, f''(x) = n(n-1)x^{n-2}$, &c.; and by substitution of these values we obtain Newton's *binomial* theorem; if the function be a^{x+h}, Taylor's series gives us as its equivalent $a^x(1 + h \cdot \log. a + \frac{h^2}{1.2}(\log. a)^2 + \ldots.)$; and Maclaurin's gives $a^h = 1 + h \cdot \log. a + \frac{h^2}{1.2}(\log. a)^2 + \ldots.$, which latter is the *exponential* theorem, and may be obtained from Taylor's series by division; if the function be $\log.(1+x+h)$, ($\log. x+h$ being one of the cases in which Taylor's theorem fails), then Maclaurin's series gives the *logarithmic* theorem, $\log.(1+h) = h - \frac{h^2}{2}+\frac{h^3}{3}-$, &c.; and the same theorem gives the various series expressing the values of sin. h, cos. h, sin. ^{-1}h, &c. &c.

The history of this celebrated theorem is remarkable. On the first publication of the *Methodus Incrementorum*, it was entirely neglected by Leibnitz, who, in ignorance of its value, severely criticised the whole work; while the bitter hostility of John Bernouilli to British men of science, blinded him to the existence of any merit in any part of the work. The theorem never appeared in any of the works on the calculus published before D'Alembert's *Recherches*, and after that, was given only in the French *Encyclopædia;* but neither D'Alembert nor Condorcet seems to have known that it was Taylor's, or to have fully appreciated its importance; and it was not till Lagrange, in the *Berlin Memoirs* for 1772, gave the name of its true author, and proposed to make it the foundation of the differential calculus, that it assumed that important position which it deserved to hold.

TCHAD, or TSAD, LAKE, a large lake in Sudan, Northern Africa, lat. 12° 30′—14° 30′ N., long. 13°—15° 30′ E. Its size varies with the time of year; it has an area of 10,000 sq. miles in the dry season, and is sometimes four or five times as large in the rainy months. According to Rohlfs, it is 1150 feet above sea-level. The shores are low, and for the most part unattractive; and a strip of swampy ground surrounds the fine open sheet of water which is the actual T., and the margin of which is lined by papyrus and tall reeds, of from 10 to 14 feet in height. Its depth in ordinary years is from 8 to 15 feet, but in some years the waters rise much higher; and of the islands, of which there are many densely peopled, only the more elevated afford shelter to the inhabitants. River-horses and crocodiles swarm in the lake and fish and water-fowl are abundant. There are several affluents. From the west, the large river Yaobe enters the lake; and from the south, the Shari, which in its lower course is upwards of 1800 feet broad. Lake T., whose waters are perfectly fresh, has no regular outlet. But Dr. Nachtigal has proved that it sometimes overflows towards a great depressed plain lying 300 miles to the north-east.

TCHELYUSKIN, CAPE, the northernmost point of Asia. It was rounded by Nordenskjöld and his party in 1878, and found by them to be in lat. 77° 41′ N. It used to be called Cape Severo.

TCHERKA'SI, a town of Russia, in the gov. of Kiev, 100 miles south-east of the town of Kiev, on the Dnieper. Pop. (1880) 14,000.

TCHERKA'SK, STAROI (Old Teherkask), a town of South Russia, formerly the capital of the Don Cossacks, stands on the right bank of the Don, 12 miles south of Novotcherkask, the present capital. Pop. 15,000.

TEA (*Thea*), a genus of shrubs of the natural order *Ternstræmiaceæ*, very nearly allied to the genus *Camellia* (q. v.), and distinguished from it only by the not deciduous calyx, and by the dissepiments remaining connected in the center of the capsule after it opens. The genus seems to derive its importance entirely from a single species, the dried leaves of which are the tea of commerce, one of the most important articles of commerce in the world, and yielding the most esteemed and extensively used of all non-alcoholic beverages. This species, the tea shrub or CHINESE TEA (*T. Sinensis*), is 20—30 feet high, but in a state of cultivation only 5—6 feet high, with numerous branches and lanceolate leaves, which are 2—6 inches long. The flowers grow singly or two or three together in the axils of the leaves; they are rather large, white, and fragrant, with 5-parted calyx, 6—9 petals, and many stamens. By cultivation for many centuries, numerous varieties of this plant have been produced in China, some of which have been reckoned as distinct species, particularly *T. viridis*, formerly supposed to yield green tea, *T. Bohea*, formerly supposed to yield black tea, and *T. stricta*. Of these, the first-named has the longest, and the last has the shortest leaves. The Assam Tea, which has been called *T. Assamensis*, appears also to be a mere variety of the same species.

Tea Plant (*Thea Sinensis*).

The cultivation of tea in China is chiefly confined to the regions between N. lat. 24°—35° and E. long. 115°—122°. Tea for domestic use is, however, cultivated both in more southern and more northern regions. The plant is to be accounted subtropical, but bears a tropical climate well, and can also accommodate itself to cold winters. In the neighborhood of London it often endures all the frost of winter without protection. In few of the countries into which it has been introduced, however, is the flavor of the dried leaf such as it is in China. The use of tea is said to have been introduced into China itself from the Corea about the 4th c. of the Christian era, and to have extended to Japan about the 9th century. The Chinese cultivate it chiefly on the southern slopes of hills. A new plantation is made by sowing the seed in holes at proper distances, two or three seeds being put into a hole to secure a plant. The first crop is obtained in the third year, when the shrub is by no means full-grown. When about seven years old, it yields only a scanty crop of hard leaves, and is cut down, when new shoots rise from the root, and bear fine leaves in abundance. This is repeated from time to time, till the plant dies at about the age of thirty years.

History and Commerce.—All that can be affirmed regarding the early history of this beverage is, that it appears to have been used for ages in China, where it is believed by the natives to be indigenous. It first became known to Europeans at the end of the 16th c., though it is only mentioned by the Portuguese writer Maffei in his *Historiæ Indicæ*, who refers to it as a product both of China and Japan. The first reference to it by a native of Britain is in a letter dated 27th June 1615, written by a Mr. Wickham, which is in the records of the East India Company; and it is curious to observe that both the Portuguese and English writers referred to use their own rendering of the native name, which is *tcha*. Maffei calls it *chia*, and Mr. Wickham, *chaw*. From this time, it became gradually known to the wealthy inhabitants of London, in the form of occasional presents of small quantities from India, obtained from China, or by small lots in the markets from time to time, but always exorbitantly dear, fetching sometimes as much as £10 the lb., and never less than £5.

A rather large consignment was, however, received in 1657; this fell into the hands of a thriving London merchant, Mr. Thomas Garraway, who established a house for selling the prepared beverage; and that house, under the name of 'Garraway's Coffee-house,' is still a famous establishment in that city. From 1660 until 1689, a duty was levied on the drink made with tea at the rate of 8*d*. per gallon; but from the latter date a duty of 5*s*. per lb., with an addition of 5 per cent. *ad valorem*, was levied. For many years, the duties, although occasionally changed, were always very high, and were levied by both the Customs and the Excise. The expiration in 1833 of the charter of the East India Company, which had held a complete monopoly of the tea-trade, produced a change; the *ad valorem* duty was abolished, and differential duties of 1*s*. 6*d*., 2*s*. 2*d*., and 3*s*. per lb. were substituted; but they worked badly, and were abandoned in 1836 for one uniform rate of 2*s*. 1*d*. per lb., to which, in 1840, was added an additional 5 per cent. From that time to the present, several changes, always reductions, have taken place, until now, when the duty is only 6*d*. per lb. The import for the year 1875 was nearly 200,000,000 lbs., value about £14,167,000; the import for 1876 was 185,668,190 lbs., value £12,812,832; for 1880, 206,971,000 lbs., value £11,613,398.

Much mystery and error for a long time existed upon the subject of the species producing the tea of commerce. By many it was said that the qualities known as black teas were produced by the species known to botanists as *Thea Bohea*, and the green teas from *T. viridis*. Others held that only one species was used to make both the black and green varieties, and that the difference arose from the method and time of preparation.

The eminent botanical traveler, Mr. Robert Fortune, has, however, entirely set the question at rest by investigating the matter on the spot. He found that in the Canton district, where black teas alone are prepared, only the *T. Bohea* is grown; whilst in the province of Che-kiang only *T. viridis* is grown, and green teas made. But the cultivation of the latter plant he also found to be absolutely universal in the Fokien district, although the inhabitants make only black teas. The tea-farms are mostly in the north of China, and are usually of small size, and require much attention; for the plant will only thrive in well-matured or very rich soil, and the spaces between the plants, which are four feet apart, must be kept in good order, and free from weeds. The farms always occupy the hill-sides, where the soil is deep and well drained. Although an evergreen, the leaves can only be gathered at certain seasons: the first is in April, when the new leaves begin to burst from the buds; and some of these in their most tender state are gathered and made into young hyson of the finest quality; so fine, indeed, that it has rarely been brought to England, because it is said to lose flavor by the sea-voyage. Much is, however, sent overland to Russia, where it fetches an exorbitant price. The ordinary picking begins just after the summer rains are over, at the beginning of May; and later in the season, a third picking takes place, the produce of which is inferior, and used only by the poorer classes of the country. The later gatherings are more bitter and woody than the earlier, and yield less soluble matter to water. The leaves, when freshly plucked, possess nothing of the odor or flavor of the dried leaves, these properties being developed by the roasting which the leaves undergo in the process of drying. Moreover, different qualities of tea are prepared from the same leaves, which may be made to yield green or black teas at will.

For a description of the processes for obtaining the green and the black teas, we refer to Fortune's *Tea Countries of China*, Johnston's *Chemistry of Common Life*, and Money's *Cultivation and Manufacture of Tea* (3d ed. 1879). It is sufficient here to remark, *first*, that, in the process of drying, the leaves are roasted and scorched in such a way as necessarily to induce many chemical changes in them; the result of such changes being to produce the varieties of flavor, odor, and taste by which the different kinds of teas are distinguished; and *secondly*, that the different colors of green and black teas are due to the mode in which the leaves are treated. For *green teas*, the leaves are roasted in pans almost immediately after they are gathered. After about five minutes' roasting, during which they make a cracking noise, become moist and flaccid, and give out a good deal of vapor, they are placed on the rolling-table, and rolled with the hands. They are then returned to the pans, and kept in motion by the hands: in about an hour, or rather more, they are well dried, and their color, which is a dull green, but becomes brighter afterwards, has become *fixed*. The essential part of the whole operation is now over, nothing more being required than to sift and re-fire it. For *black teas*, the leaves are allowed to be spread out in the air for some time after they are gathered; they are then further tossed about till they become flaccid; they are next roasted for a few minutes, and rolled, after which they are exposed to the air for a few hours in a soft and moist state; and lastly, they are dried slowly over charcoal fires, till the black color is fairly brought out. Hence the dark color and distinguishing flavor of black teas seem due to the long exposure to the atmosphere in the process of drying, and the oxygen of the air acting rapidly upon the juices of the leaf, and especially upon the astringent principle during this exposure. For the purpose of giving special scents to different varieties of tea, numerous odoriferous plants are employed in different parts of China; the cowslip-colored blossoms of the sweet-scented olive (*Olea fragrans*) communicate an especially fragrant scent to tea.

The adulteration of tea, when the duty was very high, was

probably carried on to a great extent, but notwithstanding the terrible tales of alarmists, it may be asserted that very little adulteration of tea is now carried on in Great Britain. In China, spurious teas have been prepared and sent to this country under the name of 'Lie teas,' but they had no sale, and of course were discontinued. The Chinese give an artificial coloring to the green teas sent to Europe because it pleases the eye, but the coloring matter is very innocuous, and is never produced by heating over copper plates—a popular error, which has been persisted in for a long time without a shadow of truth for its foundation. Prussian blue in very minute proportion, and a species of native indigo and gypsum, are the real materials employed for giving the face, as it is called.

In 1836, the culture of tea was attempted on a large scale in India, under the direction of the able and indefatigable botanists, Dr. Royle and Dr. Falconer; and after some difficulty, a good supply of plants was introduced to the districts of Kumaon and Gurhwal, and in the meantime plantations formed at an earlier period in Assam were making great progress. From these sources a steadily increasing supply is received, the value of which in 1880 was £3,072,922. The quality, too, is superior to many of the Chinese teas, a fact which is testified by the large quantity of Indian teas now used. Japan and Java export tea to Australia. In the Brazilian high lands, tea of most excellent quality is produced in large quantities. A little has of late been grown in New Zealand and in Sicily, near Messina.

The varieties of tea are very numerous; the following are those found in the shops of Great Britain:

GREEN TEAS.—*Chinese:* (1) Gunpowder sorts—viz., Shanghae, Ping-Suey or Pin's Head, Moyune, Imperial Moyune, and Canton; (2) Hyson sorts—viz., Shanghae, Shanghae young, Moyune, Moyune young, Canton young, and Twankay or Imperial Hyson. *Japanese:* Gunpowder and Young Hyson. *Java:* Gunpowder.

BLACK TEAS.—*Chinese:* (1) Congo sorts—viz. Canton, Foochow-foo, Hung-muey, Oopack, Kaison, and Oonam; (2) Pekoe sorts—viz., Plain Orange, Foo-chow, Scented Orange, Canton Scented Orange, and Flowery Pekoe, Oolong, and Souchong. *Assam:* Congo, Orange Pekoe, and Souchong. *Java:* Congo and Imperial. The latter is made up into little balls about the size of a pea, and is rather rare.

The use of the infusion of the leaves of tea as a beverage is general in the south-eastern parts of Asia, and has become prevalent also amongst the British—at home, and in all their colonies—the Americans, and the Dutch. In Scandinavia, tea is also much used by all who can afford it. In other parts of Europe, the use of tea is much less general, and is chiefly confined to maritime districts, towns, and the wealthy. The importation of tea overland through Russia is inconsiderable, and the sea trade is chiefly to Britain and North America.

The *substitutes* for tea, in countries where it is difficult to obtain it, are of two sorts: those which contain theine, and which consequently have the same stimulating effect; and those which are destitute of that principle, and only resemble the true tea in flavor or smell, or which possess some other stimulating principle. Of the former class are—(1) Maté (q. v.): (2) Guarana (q. v.); so rich is this material in theine that it has lately been used in this country for obtaining that principle; and it has been introduced into Austria and France as a powerful medicine: (3) Coffee-leaves, which are occasionally prepared as a substitute in the West Indies; they would be more generally used were it not for the disagreeable smell of the infusion: (4) the Kola-nut, the active principle of which was some years ago ascertained to be theine.*

The second class, or those which do not possess that principle, are very numerous; but only a few can be said to be of any importance from being in general use in the countries producing them. These are the Siberian tea—leaves of *Saxifraga crassifolia;* the Appalachian tea—leaves of *Prinos glabra;* the Labrador tea—leaves of *Ledum buxifolium;* the Chilian tea—leaves of *Eugenia ugni;* Trinidad pimento tea—leaves of *Eugenia pimenta;* and the leaves of the Patridge-berry, which are used in some parts of North America. The Faham tea of Mauritius, and a great many more, should be regarded in the light of medicines, rather than as ordinary beverages; although they are generally classed with the substitutes for ordinary tea.

Tea, in its Chemical, Physiological, and Medicinal Relations.—On submitting the ordinary commercial tea* to analysis, we find that it contains (1) a volatile or essential oil; (2) theine or caffeine, described in this work under the latter name; (3) a nitrogenous compound analogous to caseine or gluten; (4) a modification of tannin; besides gum, sugar, starch, fat, woody fibre, salts, &c. *The volatile oil* gives to tea its peculiar aroma and flavor. The proportion in which it exists is, according to Miller, about 0·79 per cent. in green, and 0·6 per cent. in black tea. It may be obtained by distilling the tea with water, and is found to exert a most powerfully stimulating and intoxicating effect.

In China, tea is seldom used till it is a year old, on account of the well-known intoxicating effects of new tea, due probably to the larger proportion of essential oil which it usually contains. The headache and giddiness of which tea-tasters complain, and the attacks of paralysis to which, after a few years, persons employed in packing tea are found to be liable, are due to the action of this oil, which, according to Johnston, 'does not exist in the natural leaf, but is produced during the process of drying and roasting.'—*Chemistry of Common Life*, vol. i.

The theine or *caffeine*, an alkaloid of weak basic properties, varies considerably in different kinds of tea. Peligot found it to range from 2·2 to 4·1 per cent. in ordinary green teas, while very rarely it amounted to 6 per cent.; whereas from the researches of Stenhouse it appears that not more than 2 per cent. is usually contained in the ordinary teas in the English market. It may readily be obtained by the following simple experiment. When dry finely-powdered tea-leaves, or a dried watery extract of the leaves, are put on a watch-glass covered with a paper cone, and the whole is placed upon a hot plate, or exposed to the heat of a spirit-lamp, a white vapor gradually rises and condenses on the interior of the cone, in the form of small crystals, which consist of theine. As it has no odor, and only a slightly bitter taste, it obviously has little to do with the taste or flavor of the tea from which it is extracted; it is, however, to the presence of this ingredient that the peculiar physiological action of tea on the animal economy is due. This substance is represented by the formula $C_{16}H_{10}N_4O_4 + 2Aq$, and is remarkable for the large quantity of nitrogen (28·83 per cent.) which it contains; and which is nearly double the amount contained in albumen, fibrine, &c. It is also remarkable as occurring in plants very unlike each other, and growing in remote countries, which have by instinct been selected by different nations for the purpose of yielding a slightly exciting and very refreshing beverage (see above).

From numerous experiments, it appears that the introduction into the stomach of a small quantity of theine (such as three or four grains, which is the quantity contained in about one-third of an ounce of good tea) has the remarkable effect of diminishing the daily waste or disintegration of the bodily tissues, which may be measured by the amount of solid constituents contained in the urinary secretion. And if the waste be lessened, the necessity for food to repair that waste will obviously be diminished in an equal proportion. 'In other words,' says Professor Johnston, 'by the consumption of a certain quantity of tea, the health and strength of the body will be maintained in an equal degree upon a smaller supply of ordinary food. Tea therefore saves food—stands to a certain extent in the place of food—while at the same time it soothes the body, and enlivens the mind.'—*Op. cit.*, p. 173. It should, however, be stated, that the generally accepted view, that

* Dr. Daniell's observations on the kola-nut (see the article COLA NUT, Vol. II.) are of such importance as to demand a notice here. From time immemorial, the seeds of the kola-nut have been held in inestimable value as a luxury by the inhabitants of the vast tract between the west coast and the region of Central Africa known as Sudan; and the trade in these nuts has extended to various markets on the Mediterranean. The Portuguese, Dutch, and subsequently the English voyagers, fell into the negro predilections for this fruit; and eventually the due gratification of this want became a matter of imperative necessity. Dr. Daniell's knowledge of the tonic and astringent properties of these nuts was gained during his residence on the Gold Coast, where the white inhabitants were in the habit of taking a decoction of the fresh nuts, with apparent benefit, in a particular form of endemic diarrhœa, arising more from local relaxation of the mucous membranes than from constitutional debility. On taking the medicine late, two evenings in succession, when he was afterwards suffering from an attack of this kind in Jamaica, he found that he was deprived of sleep during the remainder of the night. On intermitting the decoction, the natural rest returned, and on returning to it, the insomnia again occurred. Hence, he was led to suspect that a substance analogous to theine must be present; and a chemical analysis of the nuts yielded crystals in all respects resembling those of theine, and subsequently proved by the more careful investigations of Dr. Atfield to be composed of that alkaloid. Wherever the slave-trade prevailed, the tree yielding the kola-nut (*Cola acuminata* of Robert Brown) followed as a matter of necessity, being imported and cultivated for the benefit of the negro. It was thus introduced into the Mauritius, Jamaica, and other West India Islands, Brazil, Mexico, &c. It was specially intended to act in warding off the predisposition to epidemic outbreaks of suicidal mania, which not unfrequently almost depopulated considerable districts. While Dr. Daniell's experiments disprove the statement (alluded to in the article COLA-NUT) that these seeds render bad water palatable, his investigations, confirmed as they are by Dr. Atfield's chemical analysis, show, that whatever may be their food-value (which Dr. Daniell estimates higher, from his observations, than Dr. Atfield from their analysis), they may be advantageously substituted for coffee. See the papers by Dr. Daniell, 'On the Kola-nut of Tropical West Africa,' and by Dr. Atfield, 'On the Food-value of the Kola-nut,' in the *Pharmaceutical Journal* for March 1865.

* The following comparative analyses of tea, coffee, and the dry kola-nut are interesting, as showing how nearly they contain the same organic constituents, although in different proportions:

	100 Parts of Tea contain	100 Parts of Coffee contain	100 Parts of Kola-nuts contain
Water	8	12	13·65
Theine	3	1·75	2·13
Caseine	15	13	6·33
Gum	18	9	10·67
Sugar	3	6·5	
Starch	a trace	a trace	42·00
Tannin	26·25	4	...
Aromatic oil	0·75	0·002	1·52
Fat	4	12	
Fibre	20	35	20·00
Mineral substances	5	6·7	3·20

theine checks the destruction of the tissues, has been recently called in question by an excellent experimental observer, Dr. Edward Smith, in various Memoirs published in the *Philosophical Transactions* and elsewhere. If double the above quantity of theine (or of the tea containing it) be taken, there is a general excitement of the circulation, the heart beating more strongly, and the pulse becoming more rapid; tremblings also come on, and there is a constant desire to relieve the bladder. At the same time, the imagination is excited, the mind begins to wander, visions appear, and a peculiar kind of intoxication comes on; the symptoms finally terminating, after a prolonged vigil, in a sleep arising from exhaustion. It is not definitely known what changes theine undergoes in the animal economy, but when oxidized artificially, it becomes decomposed into methylamine or methylia (C_2H_3,H_2N), hydrocyanic acid (C_2N), and amalic acid ($C_{12}H_7N_3O_8$).

The *nitrogenous compound* allied to caseine or gluten constitutes about 15 per cent. of the weight of the leaf. As hot water extracts very little of this substance, a large quantity of this nutritious matter, which forms about 28 per cent of the dried spent leaves, is thrown away. Much of it might be dissolved if a little carbonate of soda were added to the boiling water with which the tea is made; and in the brick-tea (the refuse and decayed leaves and twigs, pressed into moulds) used by the Tartars, most of this substance is utilized. They reduce the tea to powder, and boil it with the alkaline water of the steppes, to which salt and fat have been added, and of this decoction they drink from 20 to 40 cups a day, mixing it first with milk, butter, and a little roasted meal. But without the meal, mixed only with a little milk, they can subsist for weeks on this thin fluid food. To the *astringent principle*, or *tannin*, which forms from 13 to 18 per cent. of the dried leaf, tea owes its astringent taste, its constipating effect upon the bowels, and its property of communicating an ink-like color to water containing salts of iron. Whether this ingredient contributes in any degree to the exhilarating, satisfying, or narcotic action of tea, is not known. Professor Johnston thinks it probable that it does exert an exhilarating effect, from the fact, that a species of tannin is the principal ingredient of the Indian betel-nut, which, when chewed, produces a mild and agreeable form of intoxication.

It is usual to judge of the quality of a tea by its aroma, and by the flavor and color of the infusion which it yields; but to these tests should be added the determination of the amount of soluble matter which it readily yields to boiling water. It is stated by Miller that our ordinary tea contains about 45 per cent. of soluble matter; but the independent researches of Davy and Peligot show that boiling water seldom extracts more than one-third of the weight of the dry tea; while in J. Lehmann's experiments, only one-sixth (15·5 per cent.) was extracted. Good tea should, moreover, not yield more than 5 or 6 per cent. of ash when incinerated; and a portion of this is probably due to the coloring matter which the Chinese add to the green teas prepared for the foreign market. For this purpose, they used to employ a mixture of Prussian blue and gypsum, but indigo is now commonly used, which is probably harmless.

Drinkers of green tea who wish to know which of these adulterations they are swallowing, may easily determine the point by the following simple experiment. 'If a portion of the tea be shaken with cold water, and thrown upon a bit of thin muslin, the fine coloring matter will pass through the muslin, and settle to the bottom of the water. When the water is poured off, the blue matter may be treated with chlorine, or a solution of chloride of lime. If it is bleached, it is indigo; if potash makes it brown, and afterwards a few drops of sulphuric acid make it blue again, it is Prussian blue.'—Johnston, *op. cit.*

Much has been written regarding the dietetic and medical uses of tea. While some physicians have over-praised its value, others have regarded it as the source of numerous diseases, especially of the nervous system. In his admirable work on *Hygiene*, Dr. Parkes remarks that 'tea seems to have a decidedly stimulative and restorative action on the nervous system, which is perhaps aided by the warmth of the infusion. No depression follows this. The pulse is a little quickened. The amount of pulmonary carbonic acid is, according to Dr. E. Smith, increased. The action of the skin is increased; that of the bowels lessened. The kidney excretion is little affected; perhaps the urea is a little lessened, but this is uncertain, the evidence with regard to the urine being very contradictory.' Dr. E. Smith considers that 'tea promotes all vital actions.' Dr. Parkes regards it as a most useful article of diet for soldiers, and it is well known that cold tea is frequently preferred to beer or cider by sportsmen, reapers, and others engaged in laborious work in hot weather. As a general rule, tea is very prejudicial to young children, and is not a suitable drink till growth is completed; and adults of an irritable constitution, or a leuco-phlegmatic temperament, often suffer from its use.

Those with whom tea does not agree, will generally find cocoa the best substitute. Old and infirm persons usually derive more benefit and personal comfort from tea than from any other corresponding beverage. In fevers, tea, in the form of a cold weak infusion, is often of great service. In persons of a gouty and rheumatic tendency, and especially in such as are of the *Lithic Acid Diathesis* (q. v.), weak tea, taken without sugar, and with very little milk, is the best form of ordinary drink. In some forms of diseased heart, tea proves a useful sedative, while in other cases it is positively injurious; and a cup of strong green tea, especially if taken without sugar or milk, will often remove a severe nervous headache. It is nearly as powerful an antidote in cases of opium-poisoning as coffee; and very strong tea has been the means of preserving life, in cases of poisoning by tartar emetic, the tannin being in these cases the active agent. It is impossible to speak too strongly against the habit occasionally adopted by students of keeping off their natural sleep by the frequent use of strong tea. Such a habit is certain to lead to the destruction of both bodily and mental vigor. See Money, *The Cultivation and Manufacture of Tea* (3d. ed. 1879).

TEAK, the name of two kinds of timber, valuable for ship-building and other purposes, one of which is known as INDIAN T., and the other as AFRICAN TEAK. The trees which produce them belong to very different orders. INDIAN T. (*Tectona grandis*) is a tree of the natural order *Verbenaceæ*. It is found in the mountainous parts of Malabar, and elsewhere in Hindustan, and in the Eastern Peninsula, Ceylon, Java, &c. It has been introduced in some parts of India, in which it is not indigenous.

Dr. Roxburgh introduced it in the low grounds of the Circars as early as 1790. It has been planted in some parts of Ceylon, but not yet with much result, as it takes 60 or 80 years to grow to a large size. It is a beautiful tree, attaining a height sometimes even of 200 feet, and rising above all the other trees of the East Indian forests. It has deciduous oval leaves of 12—24 inches long, covered with rough points; great panicles of white flowers, with 5—6-cleft corollo, and 4-celled drupes about the size of a hazelnut. Its flowers are used medicinally in cases of retention of urine, and its leaves by the Malays in cholera. Silk and cotton stuffs are dyed purple by the leaves. The timber is the most valuable produced in the East Indies; it is light and easily worked, strong, durable, and not liable to the attacks of insects. It abounds in silex, and resembles coarse mahogany. It is extensively used for ship-building, for which purpose it is imported into Britain. All the finest ships built in India, and many built in England, are of teak. The most extensive T. forests are in Pegu. The T. generally rather grows in clumps in forests than forms forests of itself.—AFRICAN T., sometimes called AFRICAN OAK, is a timber similar to East Indian teak. It is now believed to be the produce of *Oldfieldia Africana*, a tree of the natural order *Euphorbiaceæ;* but the leaves of many different trees have been brought to botanists as those of the African teak.

Indian Teak (*Tectona grandis*).

TEAL (*Querquedula*), a genus of ducks (*Anatidæ*) with very slightly lobed hind-toe, narrow bill, as long as the head, the sides

Common Teal (*Querquedula crecca*), male and female.

nearly parallel, or widening a little at the end, the wings pointed, the tail moderately large, and wedge-shaped. Some naturalists divide the genus into two—*Nettion*, in which the bill has parallel

sides, and a small nail at the tip; and *Querquedula* in which it is widened, and has a larger nail. The species are numerous, the smallest of the ducks, and widely distributed over the world. They generally frequent rivers and lakes, feeding principally at night on aquatic insects, worms, molluscs, seeds, &c. The COMMON T. (*Q. or N. crecca*) is plentiful in Britain and in most parts of Europe. It is occasionally but rarely seen in North America. Its whole length is about 14 inches. It is a very beautiful bird; the head of the male brownish red, the body transversely undulated with dusky lines, a white line above, and another beneath the eye, the speculum black and green. It makes its nest on the margins of lakes or rivers, of decayed vegetable matter lined with down, and lays eight or ten eggs. Its flesh is extremely delicate. It was domesticated by the ancient Romans, and seems capable of being advantageously introduced into our poultry-yards.—The GARGANEY (q. v.) is another British species.—The GREEN-WINGED T. (*Q.* or *N. Carolinensis*) of North America is very similar to the Common T., but it is at once distinguished by a white crescent in front of the bend of the wings. It is occasionally seen in Europe. In its summer migrations, it visits very northern regions.—The BLUE-WINGED T. (*Q. discors*) is very abundant in many parts of North America. It is rather larger than the Common Teal. It is easily domesticated.

TEAR-PITS. See DEER.

TEA'SEL (*Dipsacus*), a genus of plants of the natural order *Dipsaceæ* or *Dipsacaceæ*. This order consists of herbaceous and half-shrubby exogenous plants, with opposite or whorled leaves, and flowers in heads or whorls, surrounded by a many-leaved involucre. About 150 species are known, natives of the temperate parts of the Old World. In the genus *Dipsacus*, the flowers are separated from each other by long, stiff, prickle-pointed bracts. The only valuable species of the order is the FULLER'S T., or CLOTHIER'S T. (*D. fullonum*), a native of the south of Europe,

Fuller's Teasel (*Dipsacus fullonum*).

naturalized in some parts of England. It is a biennial, several feet high, with sessile serrated leaves, the stem and leaves prickly; and with cylindrical heads of pale or white flowers, between which are oblong, acuminated, rigid bracts, hooked at the point. The heads are cut off when the plant is in flower, and are used in woollen factories, and by fullers and stocking-makers, for raising the nap on cloth. No mechanical contrivance has yet been found to equal T. for this purpose; to which the hooked points, the rigidity, and the elasticity of the bracts are admirably adapted. The heads of T. are fixed on the circumference of a wheel or cylinder, which is made to revolve against the surface of the cloth. T. is cultivated in many parts of Europe, and is imported into Britain from Holland and France. It is cultivated to some extent in England, particularly in Somersetshire and Yorkshire. The seed is sown in March, on well-prepared strong rich land, and the plants thinned out to a foot apart. In August of the second year, the heads are ready to be cut. They are packed in bundles of 25 each, and about 160 such bundles are the usual produce of an acre. The flowers of T. abound in honey, and the seeds are used for feeding poultry. The root was formerly in use as a diuretic and sudorific.

TE'CHNICAL EDUCATION (Gr. *techné*, art) is education in applied art and applied science, and comprehends scientific and artistic instruction combined with practical training in industries and trades. This subject has only of late years received much attention in this country, public sense of its importance having been stimulated by comparisons drawn between the manufactures of Great Britain and those of other countries shown in the great international exhibitions held in London, Paris, Vienna, and Philadelphia.

The Exhibition of 1851 showed the industrial art of Great Britain at a very low standard, very far below that of the Queen Anne period, when Flaxman designed for Wedgwood. At that time (the time of the first London Exhibition, and, indeed, throughout the first half of the present century), when an art-workman was needed in England, he had to be fetched from Paris, and at a date no further back than living memory, no lace-manufacturer at Nottingham dreamt of employing an English designer. Since 1851, technical education has been prosecuted with ever-increasing zeal on the Continent, threatening to overtake, and in some instances surpass, England in industries which had hitherto been deemed peculiarly and pre-eminently her own. The first grant made by the government of this country, expressly in aid of art-training among the classes practically engaged in industries and manufactures, was in 1836, when £1500 was granted to the Board of Trade, who administered the increasing annual grant down to 1854, when the trust devolved on the Science and Art Department. This latter body have since that date organized local technical committees in places wanting or demanding instruction in science or art; have established schools of their own throughout the country; and by means of prizes, payment on results to certified teachers of ordinary elementary schools, and scholarships, have efficiently subsidized instruction in science and art in the kingdom.

The subjects of examination, upwards of 20 in number, include the ordinary branches of science, as also mining, metallurgy, navigation, nautical astronomy, steam, agriculture, and physiography; and the examinations are conducted annually all over the country, the questions being framed by a staff of eminent scientific men; the main center of the whole machinery being at South Kensington. In 1862, the Science and Art Department spent on this object £12,000; in 1871, £30,000; in 1877, £62,000; and in 1881, £70,000. The persons receiving art-instruction in elementary schools numbered in 1857, 30,000; in 1862, 71,000; in 1871, 166,000; in 1877, 541,000; in 1881, 850,000. Of provincial and national schools of art there were in 1852, 11,000; in 1863, 13,000; in 1871, 21,000; in 1877, 29,000; and in 1881, 32,000. Among the colleges subsidized by the Science and Art Department, may be mentioned Owens College, Manchester; Sir Josiah Mason's College, Birmingham; and Firth College, Sheffield.

The Government School of Mines and Metropolitan School of Science applied to Mining and the Arts was organized anew in 1881 under the title of the 'Normal School of Science and Royal School of Mines.' Its primary purpose is the instruction of teachers and of students of the industrial classes selected by competition in the science schools of the United Kingdom. Through the exhibitions attached to the yearly examinations of the Science and Art Department, this institution places a training in science within the reach of promising students in all parts of the country. The instruction comprises chemistry, biology, geology, agriculture, metallurgy, and mining.

It must be borne in mind that the instruction of the Science and Art Department is exclusively theoretical, and thus only indirectly infuses the principles of science and art into the industries and trades of our country.

In 1878, a number of the city guilds of London associated to promote or organize, or, it might even be said, initiate technological education proper, an association which has since been joined by successively more of the city guilds, and latterly by the corporation. In November of that year (1878) was provisionally constituted 'The City and Guilds of London Institute for the Advancement of Technical Education.' 22 of the Livery Companies, including 9 out of the 12 great guilds, are represented on the Council of the Institute, and jointly contribute £21,000 annually to its funds. At first the Association limited its functions to subsidizing technical education in schools and colleges in London; University and King's Colleges, London, in particular, receiving grants towards the support of professorships of Technical Science and Art. Latterly, the Institute has planted schools of its own for technical instruction, and has assisted in the development of technical education in a large and ever-increasing number of towns throughout the land. At Kennington, it has established a South London Technical Art School, where to an ever-augmenting number of pupils, likely soon to require additional accommodation, lectures and practical instruction, both in day and evening classes, are given in modelling, design, wood-engraving, and china-painting. For several years past, the City and Guilds of London Institute has with most marked success been conducting in class-rooms in the middle-class school, Cowper Street, London, technical classes for the instruction of artisans in applied chemistry and applied physics. In 1881, these classes counted 422 students, mostly artisans.

In May 1881, the foundation-stone of a great technical college

was laid in Tabernacle Row, 'Finsbury College,' estimated to cost £27,000, and expected to be finished, and wholly or at least partially open for classes by the autumn of 1883. This college, large and commodious, which will be fully equipped with all appliances, is intended to discharge 'the functions of a finishing school for those entering industrial life at a comparatively early age; of a supplemental school for those already engaged in the factory or workshop; and of a school preparatory to the Central Institution.' Its four departments are: (1) Mathematical and Mechanical; (2) Physical; (3) Chemical; (4) Applied Art. At the head is the principal or superintendent of studies. Over each department is a professor, assisted by demonstrators. There are, in addition, lecturers and teachers in special subjects. Skilled artisans, moreover, will be employed in the workshops by way of guidance to the students. Examinations in technology, initiated by the Society of Arts, having been taken over by the City and Guilds of London Institute in 1879, have provoked efforts in different parts of the country to establish and equip local technical schools. At Manchester, Preston, Dewsbury, Hawick, Sheffield, Leicester, &c., schools are being organized to instruct artisans and others in the application of science and art to particular industries. At Nottingham, £500 (with an annual grant of £300 for a limited time) has been given by the Institute towards establishing technical classes there in connection with the University College; and Manchester has been promised by it £300 a year towards the conversion of the Mechanics' Institute there into a technical school. The following table shows the rapid development both in area and bulk of the technical examinations conducted under the auspices of the City and Guilds of London Institute:

TECHNOLOGICAL EXAMINATIONS.

Year.	Number of Centers.	Number of subjects of examination.	Number of Candidates.	Number of Candidates who passed.
1879	23	7	202	151
1880	85	24	816	515
1881	115	28	1563	895
1882	147	37	1972	1222

To crown the whole, the head guardians of technical education in the United Kingdom have taken in hand the building, establishment, and equipment of a great Central Institution at South Kensington, on a valuable site leased at a nominal rental for 999 years by the Commissioners for the Exhibition of 1851. The foundation-stone of this building—the estimated cost of which was £75,000, mostly already subscribed and guaranteed—was laid in July 1881; and the whole edifice will, it is anticipated, be finished towards the end of 1884. It will be fully furnished with laboratories on the most complete scale, with workshops, lecture-theaters, and class-rooms. It is designed to supply a professional training to sons of manufacturers hitherto compelled to pursue their studies abroad, and to complete the training of artisans who have won distinction in branch or provincial colleges, and who, by scholarships from the Institute, or by the aid of their home colleges, or local societies, or of public-spirited individuals, are enabled to avail themselves of the finishing instruction in the Central Institution. Lastly, this college is intended to train a competent body of technical teachers, of whom the country is at present so much in want, to diffuse to the remotest parts of the land the highest theoretical and practical knowledge of the crafts and industries.

A royal commission, appointed in 1880, and on which the City and Guilds of London Institute was represented by Professor Roscoe and Mr. Philip Magnus, instituted inquiries into the comparative state of the manufactures, trades, &c. of this country and the Continent.

The certificates awarded by the Institute on examination are diplomas of both theoretical and practical efficiency in the subjects for which they are given. Candidates for the Institute's full technological certificate must have passed the Society and Art Department's examinations in two specified subjects in the elementary stage; and for the Institute's full technological certificate with honors (required of technical teachers), two specified subjects in the advanced stage.

The results of all this popular education in art and in technology, directly and indirectly, are already most patent and gratifying. No Nottingham manufacturer need any longer seek a designer on the Continent, but is able, with home skill, to hold his own aggressively against any lace-manufacturer in the world. At the Paris Exhibition in 1878, the French saw themselves outstripped by the English in the production of some art-manufactures. The development of artistic taste in England has caused a great increase in our export trade.

We have thus established among us a widespread and rapidly-extending system of education, already in near prospect universally national, which addresses the immediate wants and capacities of even the lowest stratum of society. This education is of more immediate benefit, and more immediately and widely intelligible and applicable, than any book-learning; it ennobles with an intellectual and artistic character the common day-labor of the nation, and puts the lowest section of the people into vital communication with its science and æsthetics. Giving, so far, free scope to all men to achieve, each for himself, that place in the national organization which is his by inward title, this system, moreover, directly tends to raise the material status and well-being of our country. The elementary schools are subsidized on one hand to teach pure science and art under the guidance and aid of the Science and Art Department; on the other hand, to teach scientifically, artistically, and practically, the useful arts, industries, and trades of the country, under the head superintendence of the City and Guilds of London Institute. The more promising pupils, again, are by means of prizes and scholarships enabled to prosecute their studies at colleges in London and elsewhere, and to complete their technical education in the Central Institutions. Finally, the students receive diplomas of their attainments, diplomas which will pass muster all over the land.

That a practicable career is now brought home to the lowliest laborer's son in the country, and that the poorest day-drudge may in this way become the executor of the nation's wisdom and taste: what an incalculable boon is implied in that alone! It will not do, however, for Britain to relax her efforts in this direction if she is to hold her own with the Continent. The Continent is making, and has long been making, much greater exertions than ourselves in the cause of technical education. In Paris, gratuitous instruction in art is offered to all workmen employed in certain trades. In 1881, the municipality of Paris spent £32,000 for this purpose, and last year still more—altogether, spent double the amount on educating its 1,900,000 inhabitants which London spent on its 4 millions. The Technical School of the Ecole Centrale, in Paris, is about to be removed to the neighborhood of the celebrated *Conservatoire des Arts et Métiers*, and the cost of the new building, according to the plans already approved, is to be 6 million francs, or nearly £240,000. All over France, art and technical shools are supported by the government and the several municipalities. At Liege, in Belgium, again, 6000 young men are engaged every night in the art and science schools. Switzerland and Germany are equally active, and equally lavish of expenditure in this direction.

Among the most successful of the older art institutions are the Watt Institution (School of Arts) at Endinburgh, and Anderson's College at Glasgow. The former was established in 1821, and for more than 30 years the principal subjects taught were mathematics, natural philosophy, chemistry, and mechanical drawing. Within the last 20 years other subjects have been added, and the total number of students is now between 1000 and 1500 annually. The evening courses of Anderson's College, where much the same subjects are taught, are likewise very largely attended by artisans.

The Journal of the Society of Arts, the Reports of the Science and Art Department, and the Reports of Select Committee and the Royal Commission above referred to contain much interesting information on this ubject.

TECHNO'LOGY (Gr. *techne*, art) is the name given to the science or systematic knowledge of the industrial arts. In its widest sense, it would embrace the whole field of industry, but it is restricted in usage to the more important manufactures (spinning, weaving, metallurgy, brewing, &c.). Technology is not an independent science, having a set of doctrines of its own, but consists of applications of the principles established in the various physical sciences (chemistry, mechanics, mineralogy, &c.) to manufacturing processes. A complete course of instruction in technology could only be of the most superficial kind. The essential preparation for any branch of the manufacturing arts is the study of the fundamental physical sciences which are taught in schools and universities; and the special applications to the branch which the student has to pursue professionally can be best be learned from special treatises on the subject in connection with practice in a manufacturing establishment. A general knowledge, however, of the arts of manufacture is interesting and instructive to all, and hence the museums of industry recently established by the British government, and yet in their infancy, promise to be of great benefit to the public in general, as well as to the manufacturer. See TECHNICAL EDUCATION.

TECTIBRANCHIA'TA, an order of gasteropodous molluscs, having the gills arranged only on one side, resembling pinnatifid leaves, and covered by the mantle and a small shell. The T. feed mostly on sea-weeds, but some of them also eat animal substances. To this order belongs the Sea-hare of the Mediterranean (*Aplysia depilans*), which is sometimes a foot in length, and was in former times an object of superstitious dread, on account of its

grotesque form, and of a violet-colored fluid which it ejects from the inner surface of the mantle when molested, and which was supposed to be poisonous.

TE DEUM (*Te Deum laudamus, Te Dominum confitemur*), a well-known hymn (so called from its first words) of the Roman Catholic Church, sung on all occasions of triumph and thanksgiving, and a theme upon which the most celebrated composers have from time immemorial exercised their musical genius. The hymn is one of the most simple, and at the same time the most solemn and majestic in the whole range of the hymnology of the Roman Catholic Church. Its authorship is uncertain. An ancient chronicle (long posterior, however, to the supposed date of the composition of this hymn, and otherwise destitute of authority) describes the Te Deum as the joint production of Sts. Ambrose and Augustine, into which they both burst forth by a common inspiration on occasion of the baptism of Augustine. From this supposed origin, the Te Deum is commonly called the Ambrosian Hymn. It is ascribed by other authorities to Hilary of Poitiers, but is most probably considerably later. Besides its general use on occasions of joyous celebrations, the Te Deum forms part of the daily 'Matins' of the Roman Breviary, and is recited at the end of 'Matins' on all festivals, and on all Sundays except those of Advent and Lent, to which, as being seasons of penance, the Te Deum is considered inappropriate. Its use is very ancient. It is universally admired by Protestants as well as Roman Catholics, and exhibits none of the peculiarities of Roman Catholic theology.

FEEL-SEED. See OILS and RAM-TIL.

TEES, a river in the north of England, is 90 miles long, flows east, forming the boundary between the counties of Durham (q. v.) and York (q. v.), and falls into the North Sea, ten miles below Stockton, to which town it is navigable for vessels of 60 tons burden.

TEETH, THE. A tooth is described by Professor Owen, a very high authority on this subject, as 'a hard body attached to the mouth or commencement of the alimentary canal, partially exposed when developed. Calcified teeth are peculiar to the vertebrates, and may be defined as bodies primarily, if not permanently, distinct from the skeleton, consisting of a cellular and tubular basis of animal matter containing earthly particles, a fluid, and a vascular pulp.'—*The Anatomy of Vertebrates*, 1866, vol. i. p. 359. 'They present,' says the same writer, 'many varieties as to number, size, form, structure, position, and mode of attachment, but are principally adapted for seizing, tearing, dividing, pounding, or grinding the food.* In some species, they are modified to serve as formidable weapons of offence and defence; in others, as aids in locomotion, means of anchorage, instruments for uprooting or cutting down trees, or for transport and working of building materials. They are characteristic of age and sex; and in man they have secondary relations, subservient to beauty and to speech. Teeth are always intimately related to the food and habits of the animal, and are therefore highly interesting to the physiologists; they form, for the same reason, important guides to the naturalist in the classification of animals.'—*Circle of the Sciences; Organic Nature*, vol. i. p. 264.

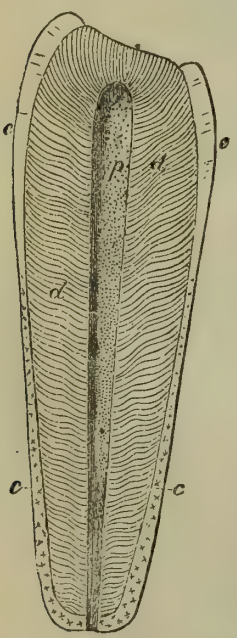

Fig. 1.—Section of Human Incisor Tooth, magnified.
c, c, the cement; *d, d*, the dentine; *e, e*, the enamel, partly chipped off on the crown; *p*, the pulp-cavity.

True teeth consist of one, two, or more tissues, differing in their chemical composition and in their microscopical appearances. 'Dentine,' which forms the body of the tooth, and 'cement,' which forms its outer crust, are always present; the third tissue, the 'enamel,' when present, being situated between the dentine and cement. The *dentine*, which is divided by Professor Owen into hard or true dentine, vaso-dentine, and osteo-dentine, consists, according to that physiologist, of an organized animal basis, disposed in the form of extremely minute tubes and cells, and of earthy particles; these earthy or calcareous particles being either blended with the animal matter of the interspaces and walls of the tubes and cells, or contained in a minutely divided state in their cavities. The tubes and cells contain, besides the calcareous particles, a colorless fluid, which is probably transuded blood plasma, or *liquor sanguinis*, and contributes to the nutrition of the dentine. In hard or true dentine, the *dentinal tubes* proceed from the hollow of the tooth known as the *pulp cavity*, in a slightly wavy course, nearly at right angles to the outer surface (see fig. 1). 'The hard substance of the tooth is thus arranged in hollow columns, perpendicular to the plane of pressure, and a certain elasticity results from these curves; they are upright where the grinding surface of the crown receives the appulse of the opposing tooth, and are horizontal where they have to resist the pressure of contiguous teeth. The tubuli, besides fulfilling the mechanical ends above stated, receive the plasma transuded from the remains of the vascular pulp, which circulates by anastomosing branches of the tubuli through the dentine, maintaining a sufficient, though languid vitality of the system.

'The delicate nerve-branches on the pulp's surface, some minute production of which may penetrate the tubuli, convey sensations of impressions affecting the dentine—sensations of which every one has experienced the acuteness, when decay has affected the dentine, or when mechanical or chemical stimuli have "set the tooth on edge;" but true dentine has no canals large enough to admit capillary vessels with the red particles of blood.† When a part of the primitive vascular pulp from which the dentine is developed, remains permanently uncalcified, red blood is carried by 'vascular canals' into the substance of the tissue. Such dentine is called *vaso-dentine*, and is often combined with true dentine in the same tooth, as, for example, in the large incisors of certain rodents, the tusks of the elephant, and the molars of the extinct megatherium. Another modification of the dentine is when the cellular basis is arranged in concentric layers around the vascular canals, and contains 'radiated cells,' like those of bone: this is termed *osteo-dentine*, and resembles true bone very closely. The *cement* always corresponds in texture with the osseous tissue of the same animal, and wherever it occurs in sufficient thickness, as on the teeth of the horse or ox, it is traversed like bone by vascular canals. Moreover, when the osseous tissue contains minute radiated cells, precisely similar cells are likewise present in the canal, and constitute its most marked characteristic. The relative densities of dentine and cement vary according to the amount of earthy matter. In the complex grinders of the elephant and some other animals, the cement, which forms nearly half the mass of the tooth, wears down sooner than the dentine. The *enamel* is the hardest of all the animal tissues, and contains no less than 96·4 per cent. of earthy matter (mainly phosphate of lime), while dentine contains only 72 per cent., and cement and ordinary bone only 69 per cent. of earthy matter. The earthy matter is contained in comparatively wide canals, composed of animal membrane of extreme tenuity.

In tracing the teeth upwards from their simplest to their most complicated forms, we find a very few examples (solely among fishes—as, for example, the wrasse), in which teeth consist of a single tissue—a very hard kind of non-vascular dentine. Teeth

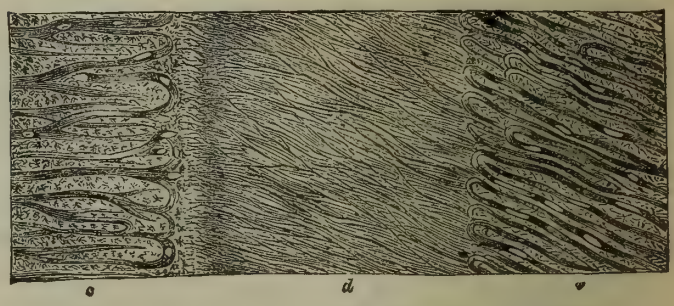

Fig. 2.—Magnified Section of a Molar Tooth of the Megatherium.
v, vaso-dentine; *d*, dentine; *c*, cement.

consisting of dentine and vaso-dentine are very common in fishes, the hard dentine being external, and performing the office of enamel. Dentine and cement, the latter forming a thick outer layer, constitute the grinding teeth of the dugong. In the teeth of the sloth, the hard dentine is reduced to a thin layer, and the chief bulk of the tooth consists of vaso-dentine internally, and a thick crust of cement externally. 'The human teeth and those of the carnivorous mammals appear at first sight to be composed of dentine and enamel only; but their crowns are originally, and their fangs are always covered by a thin coat of cement. There is also commonly a small central tract of osteo-dentine in old teeth. The teeth called compound or complex in *Mammalia* differ as regards their composition from the preceding only by the different proportion and disposition of the constituent tissues. Fig. 3 is a longitudinal section of the incisor of a horse; *d* is the dentine, *e*, the enamel, and *c*, the cement, a layer of which is reflected into the deep central depression of the crown; *s* indicates the colored mass of tartar and particles of food which

* Hence the division of the teeth into incisors, or cutting teeth; molars, or grinding teeth; &c.

fills up the cavity, forming the "mark" of the horse dealer.'—*Organic Nature*, vol. i. p. 267. Far more complex forms of teeth than this may be produced by peculiar arrangements, chiefly inflections, of the tissues.

Fig. 3.—Longitudinal Section of the Incisor of a Horse.

Certain fishes, and a family of gigantic extinct batrachians, to which Owen has, from this remarkable peculiarity, given the name *Labyrinthodons* (q. v.), exhibit this kind of complexity in a remarkable degree. Another kind of complication is produced by an aggregation of many simple teeth into a single mass. These compound teeth are most common in fishes, but are occasionally met with in mammals. The teeth of the Cape ant-eater (*Orycteropus*), depicted and described by Owen in *The Circle of the Sciences*, are of this kind, each tooth being composed of a congeries of long and slender prismatic denticles of dentine, which are cemented together. In the elephant, the compound molars belong to this class, the denticles being in the form of plates vertical to the grinding surface, and transverse to the long diameter of the tooth. When the tooth is bisected vertically and longitudinally, the three substances, dentine, *d*, cement, *c*, and enamel, *e*, are seen blended together (see fig. 4).

Our limited space forbids our entering into any details regarding the teeth of *fishes*, further than to remark, that, in regard to their

Fig. 4.—Longitudinal Section of part of an Elephant's Grinder.

number, form, substance, structure, situation, or mode of attachment, they offer a greater and more striking series of varieties than do those of any other class of animals. In all fishes, the teeth are shed and renewed, not once only, as in mammals, but frequently during the whole course of their lives; and, as Professor Owen observes, 'this endless succession and decadence of the teeth, together with the vast numbers in which they often coexist in the same fish, illustrate the law of vegetation or irrelative repetition, as it manifests itself on the first introduction of new organs in the animal kingdom.' While comparatively few fishes are entirely devoid of teeth, we find that in the class of *Reptiles*, the whole order of *Chelonia* (tortoises and turtles), the family of toads (*Bufonidæ* in the order *Batrachia*), and certain extinct genera of *Sauria* (lizards), are toothless. Frogs have teeth in the upper, but not in the lower jaw. Newts and salamanders have teeth in both jaws and upon the palate; and teeth are found on the palate as well as on the jaws of most serpents.

In most lizards, and in crocodiles, the teeth are confined to the jaws. The teeth in reptiles are for the most part simple, of a conical form, and adapted, as in the case of most fishes, for seizing and holding, but not for dividing or masticating the food. In no reptile does the base of the tooth branch into fangs; and, as a general rule, the base of the tooth is anchylosed to the bone which supports it. The completion of a tooth is soon followed by preparation for its removal and succession, the faculty of developing new tooth-germs being apparently unlimited in this class. For further details regarding the teeth of fishes and reptiles, the reader is referred to Professor Owen's invaluable *Anatomy of the Vertebrates*, 1866, vol. i. pp. 359—409. Birds having no teeth, we proceed to the consideration of the dental system of *mammals*—a class which includes a few genera and species that are devoid of teeth. The true Ant-eaters (*Myrmecophaga*), the Pangolins or Scaly Ant-eaters (*Manis*), and the Spiny Monotrematous Ant-eater (*Echidna*), are strictly toothless. The Ornithorhynchus has horny teeth, and the Whales (*Balæna* and *Balænoptera*) have transitory teeth, succeeded in the upper jaw by whalebone. The female Narwhal exhibits nothing more than the germs of two teeth in the substance of the upper jaw; in the male, one of these germs becomes developed into the remarkable weapon which specially characterizes the animal, and to which its generic term, *Monodon* (single tooth), is due. In the Great Bottle-nose Whale, in the adult state, there are only two teeth (here occurring in the lower jaw); whence the name *Hyperoödon bidens*. The elephant has never more than one entire molar, or parts of two, in use on each side of the upper and lower jaws; to which are added two tusks, which are modified incisors, more or less developed, in the upper jaw. Some rodents have 2 grinders on each side of both jaws, which, added to the 4 cutting-teeth, in front, make 12 in all; but the common number of teeth in this order is 20, although Hares and Rabbits have 28 each.

The number of teeth, 32, which characterizes man, the apes of the old world, and the true ruminants, is the average one of the class Mammalia; but according to Professor Owen, 'the typical number is 44.' 'I have been led,' he observes, 'chiefly by the state of the dentition in most of the early forms of both carnivorous and herbivorous mammalia which flourished during the eocene tertiary periods, to regard 3 incisors, 1 canine, and 7 succeeding teeth on each side of both jaws, as the type-formula of diphyodont* dentition.'—*On the Classification and Geographical Distribution of the Mammalia*, 1859, p. 18. A few of the Monophyodonts possess from 80 to 100 teeth. See the article MAMMALIA. The hog, the mole, the gymnure, and the opossum, are among the few existing quadrupeds which retain the typical number and kinds of teeth. The formula expressing the number of the different kinds of teeth—viz., the incisors or cutting-teeth, the canines or dog-teeth, the premolars, and the molars or true grinders, commonly known as the *dental formula*, is described in the article DENTITION, in which the *milk* or *deciduous* teeth, and the order in which they appear, are also described. It is only in the Mammals that we have a well-marked division of the teeth into the four kinds of incisors, canines, premolars, and molars, each of which claims a brief description.

The *incisors*, or cutting-teeth, are situated in front, and possess a single conical root or fang, and a vertical crown bevelled behind, so as to terminate in a sharp cutting edge. These teeth are specially fitted, as their name implies, for cutting the food. In man, there are two of these incisors in each side of each jaw. In herbivorous animals they crop the herbage; in rodents (the rabbit, hare, rat, beaver, &c.), these teeth are very much developed, and differ from any other teeth occurring in Mammals in this respect, that their growth continues throughout life; and if their length does not constantly increase, it is because their free ex-

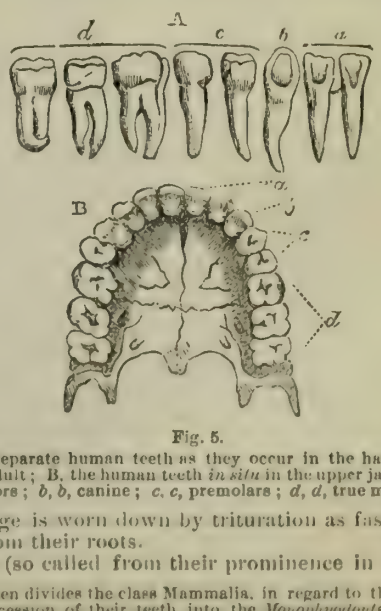

Fig. 5.

tremity or edge is worn down by trituration as fast as they grow at the base from their roots.

The *canines* (so called from their prominence in the dog) come

* Profess r Owen divides the class Mammalia, in regard to the times of formation and the succession of their teeth, into the *Monophyodonts* (Gr. *mono-*, once; *phy-*, generate; and *odont*, tooth), or those that generate a single set of teeth, as the sperm whales, dolphins, porpoises, armadillos, and sloths; and the *Diphyodonts* (derived from *di*, twice, &c.), or those that generate two sets of teeth, as the Mammals generally, with the above exceptions.

next to the incisors. Their crown is rather conical than wedge-shaped, and their fang sinks more deeply into the jaw than in the case of the incisors. In all carnivorous animals, they are largely developed, being obviously formed for tearing the flesh of their prey. In man, there is one canine tooth in each half-jaw; and there is never more than this number in any of the lower animals.

The *premolars* (known also as bicuspids and false molars) come next in order to the canines; they are smaller than the latter, and their crown presents two pyramidal eminences. In man, there are two premolars in each half-jaw. Their function more nearly approaches to that of the true molars behind them, than to that of the canines.

The *true molars* (or multicuspids) are placed most posteriorly. They are remarkable for their comparatively great size, the square form of the upper surface, on which are from three to five elevations or cusps, and for their short root, which is divided into from two to five branches, each of which is perforated at its extremity. In man, there are three molars in each half-jaw, the posterior one being termed the wisdom-tooth, from its being cut the latest: they are especially employed for grinding the food, under the action of the muscles of the lower jaw.

The teeth are so admirably adapted for the special purposes which they are called upon to fulfil, that it is generally easy, from a careful examination of them, to say to what class of animals they belong, and to draw various conclusions regarding the habits and structure of the class generally. Thus, in carnivorous animals, the molars are not grinding-teeth, but present sharp cutting edges, and those of the upper and lower jaw overlap each other; resembling a pair of scissors in their action. In insectivorous animals, the molars have a tuberculated surface, with conical points and depressions, so arranged as to lock into each other. In frugivorous animals, living on soft fruits, these teeth are provided with rounded tubercles, while in herbivorous animals, they have a broad, rough surface, resembling a millstone.

There is also a close connection between the articulation or joint of the lower jaw and the nature of the food used by the animal. Thus, in purely carnivorous animals, in which the teeth simply tear and cut the food, no grinding motion is required, and the jaw is capable only of a simple hinge-motion in the vertical plane; while in herbivorous animals, the joint is so constructed as to allow of extensive sliding and lateral motion of the lower molar teeth upon the upper. In man, both the form of this articulation and the general character of the teeth, point to an intermediate position in relation to food, and form a good physiological argument for the mixed diet which general custom has decided to be most favorable and natural to our species.—For further information on this subject, the reader is referred, not only to the three works of the professor from which quotations have been made in this article, but to his splendid *Odontography* (1844), and to his article 'Teeth,' in *The Cyclopædia of Anatomy and Physiology;* to F. Cuvier, *Sur les Dents*, &c.; and to De Blainville's *Osteographie*.

DISEASES OF THE TEETH.—The dangers to which infants and children are exposed during the process of teething, are noticed in the article DENTITION; and we shall therefore here confine our remarks to the affections of the permanent teeth, of which the following are the most important:

1. *Caries of the teeth* usually commences in the dentine immediately below the enamel, a yellow or brown spot being observed on the surface of the tooth over the affected part. The tissue soon becomes softened, and a small cavity is formed, which, after a time, presents an external opening, in consequence of the unsupported enamel giving way. The substance of the tooth now decays more rapidly, and the caries gradually approaches the central or pulp cavity, which at length is opened. Hitherto, there has been little or no suffering, but now pain is experienced under the action of irritant substances, heat, cold, &c. Inflammation proceeding to suppuration takes place; the pulp is gradually destroyed by ulceration; and the body of the tooth, thus deprived of its nourishment, decays, and leaves nothing but the outer coating of enamel, which then breaks away by degrees, till nothing but the fangs of the tooth remain, and these usually cease to give pain. Caries is not only a common cause of toothache, but frequently gives rise to obstinate headache, pain in the ear, deafness, squinting, impossibility of bearing the light (photophobia), and other anomalous symptoms, which immediately disappear upon the removal of the diseased tooth. In these cases, the tooth may never have ached, but will be found painful when pressed up or smartly struck. The primary cause of caries is constitutional, and it especially occurs in scrofulous and ill-nourished persons, or in those whose health is broken down by too frequent pregnancies, prolonged lactation, the abuse of mercury, &c.

The direct or exciting causes are usually described as: (1) Such as destroy the integrity of the enamel, and thereby expose the dentine to the influence of irritant substances; or (2) such as operate upon the vital susceptibilities of the dental tissues. Among the former are acids and other corrosive substances taken into the mouth, sour eructations, the attrition of opposing surfaces of the teeth, and all kinds of mechanical violence; while among the latter may be mentioned hot and cold drinks, especially when taken in quick alternation. The excessive use of sugar is also commonly regarded as a cause of the disease. Many of the best dentists, however, deny that acids (when taken medicinally) or the abrasion of the enamel can give rise to caries.

With regard to treatment, it may be observed, that if the caries be slight and recent, the decayed portion must be removed, and the cavity filled up with gold, as described in the article DENTISTRY. 'But,' says Dr. Druitt, who on dental matters always quotes the opinion of Mr. Tomes, one of the greatest scientific authorities on the diseases of the teeth, 'if the decay has advanced far towards the pulp-cavity, or has laid that open, it may be necessary first to employ aperients and tonics, and use some application to deaden the sensibility of the tooth, so as to enable it to bear the stopping, and to protect it meanwhile from contact with food and saliva.' Many a useless visit to the dentist might be avoided, if the patient would take an aperient dose of Epsom salts two or three consecutive mornings; and after cleansing out the cavity with dry cotton-wool, would insert twice a day a plug of that substance, moistened in Eau de Cologne, or, still better, in either of the following solutions: (1) Mastic solution, formed by dissolving a drachm of mastic in an ounce and a half of Eau de Cologne; or (2) Ethereal tincture of tannin, formed by dissolving a drachm each of tannin and mastic in an ounce and a half of sulphuric ether. By these means, a painful tooth may be often brought into a state in which it will bear stopping. The patient's sensations will warn him against drinking very hot or cold, or sweet or acid fluids, and against exposure to cold draughts of air. Whenever the teeth exhibit a tendency to rapid decay, general tonic treatment is indicated.

2. *Necrosis* is an affection which is characterized by blackness of the tooth and looseness in its socket. It may be caused by violence, accompanied with destruction of the nutrient vessels, or by inflammation of the pulp. If the tooth gives trouble, it must be extracted. Necrosis of the teeth is quite distinct from the very destructive necrosis of the dental alveolar processes and of the jaws generally, which results from the poisonous action of phosphorus fumes, or from the very similar affection which sometimes follows the eruptive fevers. For an account of the singular and terrible disease from which artisans employed in making lucifer-matches suffer, in consequence of their inhaling the fumes of phosphorus (probably in the form of phosphorus acid), which was first noticed in 1839, we may refer to a review of Von Bibra and Geist's exhaustive treatise (in German) on the subject in the *British and Foreign Medico-chirurgical Review* for April 1848; and to an article on 'Phosphorus Workers,' in the Fifth Report of the Medical Officer of Health. Reference is also made to the disease in the article PHOSPHORUS in this work. The necrosis and exfoliation of the alveolar processes and portions of the jaws in children, consequent upon the eruptive fevers, is accompanied by the shedding of the teeth; and according to Mr. Salter, surgeon-dentist to Guy's Hospital, who was the first to describe its true nature, is essentially the same as the necrosis in phosphorus-poisoning, and, like it, is the result of the local application of a specific poison, generated within the individual to the vascular parts of the teeth. For a description of this remarkable disease, and of the treatment to be adopted, we must refer to Mr. Salter's article on 'Exanthematous Jaw-necrosis,' in Holmes's *System of Surgery*.

3. *Alveolar abscess* may be defined as a suppuration around the fang or fangs of a tooth, usually carious, accompanied by absorption of the bony walls of the alveolar process, and enlargement of the little sac of pus or matter, which gradually makes its way to the surface, 'either along a canal by the side of the fang of the tooth opening at the edge of the gum, or through the gum itself at a point corresponding to the end of the root (or roots) of the tooth implicated. When, however, the fangs are unusually long, or the reflection of the mucous membrane from the gum to the cheek or lip is very superficial, this same discharge may burrow still more outwardly, and find its exit upon the surface of the face.'—Salter, *op. cit.*, p. 2. When the discharge bursts, as it most commonly does, through the gum, the alveolar abscess is reduced to its simplest form, and is known as a *gum-boil*. When the discharge takes place in the region of the cheek or chin, the true nature of the case may easily be mistaken by a careless surgeon, who might refer the symptoms to bone-disease. The cause of this affection is either caries or necrosis. In its earliest stage, the disease may be cut short by the extraction of the affected tooth, or even by the removal of the stopping, if the tooth is a stopped tooth. If it is desirable to save (for appearance' sake or otherwise) a threatened tooth, the gum should be freely leeched, and hot fomentations applied to the swollen part of the face, and the system should be briskly purged. As soon as matter can be detected, it should be allowed to escape by a puncture made through the gum—an operation which is followed by im-

mediate relief, and by rapid subsidence of the swelling, although pus continues to be discharged for a considerable time. Indeed, the disease seldom ceases altogether till the offending tooth is removed. When the abscess shows symptoms of pointing on the face, the tooth must be at once extracted, and more serious surgical interference will probably be necessary.

4. *Toothache* is not so much a disease as a symptom of various morbid states of the affected part, which, for convenience, may be classed under this single heading. 'Toothache,' says Dr. Wood, 'offers every possible variety in degree, character, and duration. The pain runs through all the grades which intervene between a slight sensation of uneasiness and unsupportable agony. It may be dull, aching, heavy, sharp, pungent, throbbing, grinding, or lancinating. It may be continued or paroxysmal, remittent or intermittent, and regular or irregular in its recurrence. It may come in flashes, and as suddenly disappear; or may continue a long time with little variation.'—*Practice of Medicine*, 4th ed. vol. i. p. 512. According to the various conditions which give rise to it, toothache may be divided into: (*a.*) *Inflammatory toothache*, which is almost always dependent upon caries. The inflammation may be seated in the pulp of the tooth, in the nerve-twig entering the pulp-cavity, or in the periosteum investing its roots, and reflected over the interior of the alveolar cavity. There is generally some external swelling after the pain has continued for some time, and it occasionally extends to the salivary glands. The tooth is at the same time very tender, and any force applied to it aggravates the pain, which is also increased by hot and cold liquids taken into the mouth. When, as in the great majority of these cases, the pain is associated with caries, the best treatment is as follows: 'Let the patient have a dose of calomel and colocynth; confine him to spoon-diet; let him wash out the mouth with a solution of carbonate of soda in tepid water; let the gum around the tooth, and between it and its neighbors, if tumid and tender, be deeply scarified with a fine lancet; then let the cavity be filled loosely with a little bit of cotton-wool, dipped into the solution of tannin and mastic (for which the formula has been already given); and if the toothache be curable at all, this plan, with a little patience, will be almost sure to succeed. If the pain is very violent, half a grain of powdered acetate of morphia may be taken up with the cotton imbued with the tannin, which should be warmed before it is put into the cavity. As soon as the pain is relieved, the tooth, if of use, should be stopped with gold or amalgam; or if of no use, it should be extracted.

It may be added, that most of the violent, burning, empirical nostrums, such as creosote, oil of thyme, &c., although they may be of service when introduced in small quantity by a skilful hand into the carious tooth at the right time, can do nothing but mischief when employed indiscriminately, as they are by the vulgar.' —Druitt's *Surgeon's Vade-mecum*, 8th ed. p. 458. (*b.*) *Neuralgic toothache* may occur either in sound or in carious teeth. It may be recognized by its occurrence in paroxysms at more or less regular intervals, and by its being attended with little or no swelling of the external parts. It is very common in the earlier months of pregnancy, and in persons of a general neuralgic tendency, and is often excited by changes in the weather. The treatment is the same as for neuralgia generally. After the bowels have been freely opened, chalybeates and quinine must be given in large doses, and frictions with veratria or tincture of aconite (both of which are energetic poisons) may be carefully applied to the gum. (*c.*) *Rheumatic and gouty toothache* may occur in sound or in carious teeth in rheumatic or gouty persons. The constitutional treatment applicable to these diseases must be tried, together with the local applications already noticed.

5. *Falling of the teeth*, due to absorption of the socket, may be regarded as almost an ordinary consequence of old age; but it frequently occurs under the popular name of *scurvy of the gums* in middle age, although very seldom before the 30th year. True scurvy, gangrene of the mouth, or mercurial inflammation of the gums, may cause the loosening of the teeth at any age; but there are two other conditions which lead to the same result. In one of these affections, the gums swell, and assume a deep red color, and the inflammation appears to be propagated into the alveoli, producing a thickening of the periosteum, and a consequent elevation of the tooth above its ordinary level. By frequently recurring attacks of this inflammation, the tooth is lifted out of its socket, while the gum retreats from the neck, and leaves a portion of the roots exposed. The tooth thus deprived of its support at length falls, after which the gum heals, and the patient is relieved. The remedies indicated are those tending to relieve inflammation of the gum, but they are seldom successful. In the other affection, there is conjoined suppuration of the gums and sockets, and the disease first shows itself by an oozing of pus from behind the edges of the gums when they are pressed. From the absorption of the sockets, and the simultaneous retreat of the gums, the teeth, as in the previous case, at length fall out, if they have not, for the patient's comfort, been previously extracted. Little can be done in the way of treatment in this form of the affection.

6. *Painful and difficult eruption of the wisdom-teeth* requires a few remarks. The cutting of these teeth is often accompanied by distressing symptoms, which may be protracted for months, or even years, unless surgical aid is called in. The difficulties 'arise from the position occupied by these teeth, so close to the joint of the lower jaw, where the mucous membrane is reflected from the gums to the cheek and fauces, combined with the very common condition, that the jaw is not sufficiently elongated backwards to allow the *dentes sapientiæ* to range in the horizontal series with the other teeth.' This mechanical difficulty not only holds back these teeth in their bony bed, but it often prevents their proper direction of growth. As a consequence of these displacements in the upper jaw, it often happens that when the jaws are brought together, a bit of mucous membrane is nipped and pinched, leading first to ulceration and extreme tenderness, and subsequently to cicatrization and stiffness of the parts. From insufficient room in the lower jaw, the crown only partially emerges through the gum, the first cusp coming through it, while the hinder cusps remain covered. This produces a terrible pinching of the mucous membrane over the tooth every time the jaws are brought in contact. Another troublesome symptom, often associated with the painful cutting of a lower wisdom-tooth, is spasmodic but continuous contraction of the masseter muscle, so as to keep the jaws nearly closed, and capable of only slight separation. The most distressing result, however, is the suppuration that often attends the difficult eruption of the tooth. Even in ordinary cases, when none of these complications are present, there is often a good deal of diffuse and erratic pain in cutting a wisdom-tooth. It is unnecessary to enter into the treatment, which must be left entirely to the surgeon-dentist.

7. *Hæmorrhage after extraction of teeth* has occasionally proved fatal, and is not very unfrequently a troublesome and even dangerous complication of the operation. In most of the recorded cases, there has been distinct evidence of the existence of the hæmorrhagic diathesis, or, in other words, of a liability to bleeding profusely from the most trivial wounds. No better local treatment can be recommended than that which was suggested by John Hunter nearly a century ago. 'In general, it will be sufficient to stuff the socket with lint, or lint dipped in oil of turpentine, and to apply a compress of lint or a piece of cork thicker than the bodies of the adjacent teeth, so that the teeth in the opposite jaw may keep up a pressure.' Matico and saturated alcoholic solution of tannin may be equally efficacious as styptics, but are not superior to oil of turpentine. In some cases, the extracted tooth has been successfully replaced as a plug. The internal administration of astringents, such as tannin and oil of turpentine, should be combined with the local treatment.

8. The subject of *Tartar* on the teeth has been considered in a special article.

TEFF. See MEADOW GRASS.

TE'FSA, TA'DLA, or TEDLA, a town of Morocco, 135 miles north-east of the city of that name, stands in the fertile, well-peopled district of Tadla, on the banks of the Um-er-Beg. It is one of the oldest towns of the country, and its manufactures of woollen cloths and shawls are important. Together with the small town or suburb of Efza, T. contains 10,500 inhabitants, 2000 of whom are Jews.

TEGNER, ESAJAS, a Swedish poet of high reputation, was born in 1782 at Kyrkerud, in the Swedish province of Wermland, and educated at the university of Lund, where he took the degree of M.A. in 1802. In 1805 he was appointed sub-librarian to the university, and lecturer on æsthetics. In 1811, the Academy prize was awarded to T.'s poem of *Svea*, or Sweden, which at once raised him to the rank of one of the most popular writers of his country. Prior to the appearance of this successful poem, he had written several spirited war-songs and national odes, which had attracted the favorable notice of the king and government. In 1812, he became professor of Greek, and at the same time was ordained to the pastoral care of the parish of Stäfje. During the next ten or twelve years of his life, he devoted himself to the prosecution of his clerical duties, and the acquisition of theological learning, with an earnest and unwearying zeal which was scarcely to be expected from his previous indulgence in the pleasures of society, and his natural inclination towards the exhibition of a taste for coarse humor and equivocal puns. During this period, he composed his two famous religious idyls of *Prestvigelsen*, or the 'Consecration of a Priest,' and *Nattvardsbarnen*, or 'The Young Communicants,' and wrote his *Axel*, a poetic romance, which is regarded by some Swedish critics as even superior to his *Frithiof's Saga*, of which the first cantos appeared in a literary journal, edited by the historian Gejer, under the title of the *Iduna*, and conducted under the auspices of the Gothic Society, the leading object of which was to foster national literature, and put down the prevalent taste for the pedantic classical or foreign school of writing.

In 1825, T. published the closing parts of *Frithiof's Saga* which

rather errs in the opposite direction, and follows too closely the ancient saga on which the tale is founded. But notwithstanding the inharmonious character of the composition, which may be regarded rather as a collection of many ballads and odes in various metres than as a complete epic, the *Frithiof's Saga* became the most popular poem of Sweden, and attracted to its author the admiration and notice both of his fellow-clergy and of the sovereign, as was evinced in 1824 by the clergy of the diocese of Wexio nominating him for the vacant bishopric, and the king at once appointing him to the see. In his place at the Diet, as a member of the Chamber of the Clergy, he made himself conspicuous for his support of ultra-conservative views, in opposition to the extreme liberal doctrines which he had advocated in early life. His speeches in the Chamber and on numerous other public occasions have a great reputation in Sweden and Norway, and are devoted to the discussion of questions of education, literature, and finance. In 1839, T. was proposed for the archbishopric of Upsala; but in the following year, he was seized with unmistakable symptoms of insanity, which had been strongly manifested in two of his brothers and other members of his family. Although, after a few months confinement in an asylum, he was able to return to his work, his health soon broke down; and after lingering for many months in a paralytic condition, he died in 1846. His collective works were edited by his son-in-law, Professor Böttiger, and published in 6 volumes (Stock. 1848). All his large and more popular poems have been translated into German, French, and English; the English translations of his *Frithiof* are very numerous, three or four new ones having appeared between 1873 (Spalding's) and 1879. Longfellow's is well known.

TEGUCIGA'LPA, a town of Honduras, Central America, is situated on a table-land 3426 feet above the sea, 25 miles south-east of Comayagua. T. is the largest and finest city in the state. Near it are gold, silver, and copper mines. Pop. 12,000.

TEHRA'N, frequently spelled TEHERAN, capital of Persia, and of the province of Irak-Ajemi, 70 miles south of the shore of the Caspian Sea. It stands on a wide plain, dotted here and there with mud-built villages, and pierced with many circular pits, which reach down to the great subterranean water-courses, on which, in this region, the life of animal and plant is altogether dependent. On the north-east runs the lofty range of the Elburz Mountains, rising in Demavend to the height of 22,000 feet above sea-level, and giving dignity to an otherwise tame and unattractive scene. The town is built almost entirely of mud-houses, packed within a mud-wall 20 feet high, and 4 miles in circumference. The principal buildings are the British and Russian residences; the bázár of Taki Khan, finished in 1850—1851, at a cost of £30,000; the Ark, or Citadel—in the suburbs—is the Shah's palace, and about 2½ miles north of these, the Castle of the Kajars (Kasr-i-Kajar), the 'Windsor' of the Persian rulers. Carpets are manufactured; but the chief trades are shoemaking and the manufacture of hats and linen goods. Several telegraph lines have been recently constructed, which center at T.; and they have compelled a number of European engineers and telegraph clerks to reside in T., the number of European inhabitants in 1872 being estimated at about 50. Pop. in summer, 80,000; in winter, 120,000.—In the vicinity of T. are the ruins of Rei, the *Rhages* of Scripture, known in the time of Alexander the Great under the name of *Ragæ*, and the birthplace of Harûn-al-Raschid. —See Eastwick, *A Diplomate's Residence in Persia* (2 vols., Lond. 1864); *History of Persia*, by Clements R. Markham (1874).

TEHUANTEPE'C, a river-port of the south of Mexico, in the territory of the same name, and 10 miles above the mouth of the river Tehuantepec, in the bay also of that name. The inhabitants, 15,000 in number, are engaged in manufacturing salt and cotton fabrics, and in indigo-planting. Pearl-fishing is carried on, and a purple dye is procured from a shell-fish which abounds in the vicinity.

TEÏ'DÆ. See MONITOR.

TE I'GITUR, one of the service-books of the Catholic Church. It is properly but an extract from the Roman Missal, and contains the canon of the mass, and certain other portions of the Liturgy which do not vary with the variety of festivals or of the ecclesiastical seasons, but are always the same. It is so called from the first words of the canon, *Te Igitur, Clementissime Pater*. This service-book, as distinct from the missal, was used, and is still used by bishops, prelates, and other dignitaries; and as the 'canon' is the most sacred part of the service, oaths upon the Te Igitur were regarded as especially solemn. The Te Igitur appears to have been used as the ordeal 'of compurgation.'

TEI'GNMOUTH, a seaport, market-town, and favorite watering-place on the south coast of Devonshire, on the north side of the estuary of the Teign. In front, on the sea-side, is the wide esplanade known as the *Den*, formed of a huge bank of sand, accumulated in the course of ages at the river's mouth—one of the chief features of the place. The harbor is safe and commodious, though difficult of entrance, the channel of the river being obstructed by a shifting bar of sand. The chief imports are coal and culm; the exports, granite from Dartmoor, and china-clay; there is also a considerable sea and river fishery. T. is connected with Shaldon, on the other side of the river, by a wooden bridge (completed in 1827) of 34 spans, 1671 feet in length, with a swing over the main channel for the passage of ships. A large convent and educational establishment, founded by Miss English, was completed in 1865. The climate is mild and salubrious, and the country beautiful. It is a station on the South Devon Railway. Pop. (1871) 6751; (1881) 7100.

TEINDS, the name given in the Law of Scotland to Tithes (q. v.). In Scotland, tithes were only paid from the produce of land or cattle. The teinds of corn, called *decimæ garbales*, greater teinds, or parsonage teinds, were generally exigible from all landed property, and originally paid to the rector or parson serving the cure, a small portion being claimed by the bishop. The tithe of the produce of animals, as wool, milk, cheese, was called lesser teind, or vicarage teind, because, where due, it was paid to the vicar; but vicarage teind was only legally exigible where a usage of paying it could be shown. The teinds, supposed to be due at common law to the incumbent of the parish, had, previously to the Reformation, been largely diverted elsewhere (see COMMENDATORS); in some instances, they had been bestowed on some favorite religious house by the patron, who seemed to consider himself their absolute proprietor; in others, they had been feued to some layman. In many cases the religious house which had acquired the teinds, profited, or at least saved itself from odium, by selling them to the crown or to a lay subject; and not unfrequently the pope, who was viewed as patron of all benefices to which no one else could claim a right of presentation, granted to the lands of churchmen an exemption from the payment of teind. At the Reformation, the church-lands were claimed by the crown; those that had belonged to the religious houses were erected into temporal lordships, whose proprietors, called *Lords of Erection*, or *Titulars*, were nominally burdened with the support of the clergy, by salaries modified out of a third part of the benefices. At the majority of James VI., it was found advisable to check the practice of granting the lands of religious houses to laymen; and the church lands were declared, with certain exceptions, to be inalienably annexed to the crown.

The right to tithes was, in Scotland as elsewhere, originally made effectual by their owner drawing the *ipsa corpora*, separating every tenth sheaf after the crop was reaped. But this proceeding often became an instrument of oppression, as the proprietor was obliged to allow his crop to remain on the ground exposed to all the vicissitudes of the season, until the beneficiary chose to draw his teind; and prior to the Reformation, agreements had become common by which a certain quantity of grain, called *Rental Bolls*, was accepted in full value of teind, while leases were sometimes granted of the teinds for a money payment.

Various not very successful attempts were made during the reign of James VI. to regulate the conflicting interests of heritor and titular, and to provide the clergy with stipends which would not be illusory, out of the teinds of their respective parishes. Charles I., soon after his accession, issued, without the intervention of parliament, a revocation of all appropriations of church lands and teinds made during the two proceeding reigns. The powerful barons who were possessors of church property at first menaced resistance, but eventually showed a desire for compromise, and the parties principally concerned entered into four submissions, in which they accepted his majesty's arbitration. The decrees arbitral pronounced by the king resulted in the establishment of valuations of teinds, and sales of them to the proprietor of the lands, by which the division of the produce between the owner of the land and the owner of the teind was avoided; and the teinds were made available to their utmost extent for the support of the parochial clergy. A commission, appointed to carry out the decrees arbitral, was continued from time to time till the Union, when its authority came to be vested in the Court of Session, as Court of the Commission of Teinds, the same tribunal which still exercises jurisdiction, both judicial and ministerial, in questions relating to teinds. A heritor, and in some circumstances the minister, may pursue an action of valuation of teinds; and the heritor may also insist on purchasing the teinds of his lands when valued, that is, in paying the value of the annuity in a slump sum.

The modifying of reasonable stipends to the clergy, out of the teinds of their respective parishes, is one of the functions of the Court of Commission of Teinds. The practice of augmenting stipends after they have once been modified was introduced with some hesitation; confined at first to stipends below the minimum, it afterwards became general; and was recognized by act 48 Geo. III. c. 138, which provides that no stipend can be augmented till 20 years have elapsed from a previous augmentation. By 50 Geo. III. c. 54, it was provided that the minimum annual value of any stipend should be £150; and if such amount cannot be made up by the teinds, it is supplied from the Exchequer. See STIPEND.

The present position of the tithes of Scotland is as follows: In the majority of cases they have been purchased by the proprietors of the respective lands, after the modification of stipends to the ministers, and are held liable to the burden of augmenting those stipends to the extent or their value; in other words, there are no tithes, but part of the rent of the proprietors constitutes minister's stipend, and an additional part is liable to augmentation of stipend. A part of the tithes are in the hands of titulars, also liable to stipend and augmentation—they are, however, no longer drawn in kind, but paid according to valuation, or compounded for in the few cases where they remained unvalued. The teinds which were held before the Reformation by the bishops and other dignified clergy, are in the hands of the crown, liable to augmentation of stipend. The teinds which remained in possession of the parochial clergy, still belong to them, but are commuted; and those belonging to colleges and hospitals have in most cases been valued, and are paid by composition, but have not been sold to the owners of the lands.

TEKELI (more properly, *Tökely*), EMERIC, COUNT, a celebrated Hungarian patriot, was descended from a noble Lutheran family, and was born at the castle of Kasmark, in the county of Zips, in 1656. His father, Count Stephen, had been implicated in the conspiracy of Zriny and Ragotsky to free Hungary from the rule of Austria; and, after his death, and the execution of Zriny, and others, young T. sought an asylum in Poland, where he had large possessions. After vain endeavors to recover from the emperor his patrimonial estates, he repaired to the court of Abaffi, Prince of Transylvania, who put him at the head of an army of 20,000 men, with which, in 1678, he invaded Hungary. Being joined by numbers of the malcontents, he rapidly extended his conquests, made predatory inroads even into Austria, Styria, and Moravia, till Leopold I. was forced (1681) to temporize with the insurgents, and thus gained over a portion of them. But T. distrusting, with good reason, the emperor's sincerity, refused to disarm, and being joined by the Transylvanian prince and the Turks, he was declared by the Sultan Mohammed IV. (1682) king of Upper Hungary, and again recovered most of the country. T. joined Kara Mustapha in his celebrated inroad upon Austria; but after the failure of the expedition many of his followers fell off from him, and his patron the sultan being prejudiced by his enemies against him, he was twice imprisoned by the Turks; and during his detention, Hungary was wholly overrun by the Austrians, and Transylvania separated from the Turkish alliance. T., however, was favored by a brilliant though ephemeral change of fortune in 1690, when, at the head of a Turkish force, he burst into Transylvania, routed the combined Austrians and natives repeatedly, and woke up the energers of his partisans in Hungary; but the imperialists, under the Markgraf of Baden, routed his allies the Turks at Salankemen (August 19, 1691), and under Prince Eugene of Savoy, so completely demolished them at Zenta (September 11, 1697), that they gladly agreed to the peace of Carlovitz (November 14, 1697), by which all aid to the Hungarian malcontents was withdrawn.

From this time, T. lived in retirement in Turkey, at first being munificently entertained by the Turkish government, but afterwards so completely neglected that he was forced to adopt the occupation of a vintner. He died at Constantinople in 1705.—His wife, Helena, the widow of Ragotsky, was celebrated over all Europe for her beauty, but was no less distinguished for her heroic gallantry, as was proved by her obstinate defence of her castle of Mongatz (Hung. *Munkacs*) against an army of imperialists. Forced to surrender, to save the lives of her children and the property of her (Ragotsky's) family, she was afterwards exchanged for an Austrian general whom T. had captured; and joining her husband at the cost of abandoning her children, shared the vicissitudes of his fortune, and died in 1703.

TELAMO'NES (see ATLANTES), statues employed as columns, to support a wall, cornice, &c.

TELEDU (*Mydaus meliceps*), a quadruped of the Weasel family (*Mustelidæ*), a native of the mountains of Java, at an elevation of 7000 feet and upwards; remarkable, like the Skunk (q. v.) of America, for the excessive fetor of a volatile secretion formed in glands situated a little within the rectum, the emission of which is its principal means of defence.

TE'LEGRAM, a communication sent by Telegraph (q. v.). This word, which was coined some years ago by a writer in the *Times* newspaper, was objected to at the time by Greek scholars as a barbarous formation. According to the law of Greek compounds, *grapho*, compounded with anything but a preposition, becomes *grapheo*; therefore, with *tele*, it would be *telegrapheo*, the noun from which would be *telegraphema*. The convenient conciseness of *telegram* has, however, made it triumph over the more correct *telegrapheme*.

TE'LEGRAPH (Gr. *tele*, far off, and *grapho*, to write) is a general name for any means of conveying intelligence other than by voice or writing. The idea of speed is also implied. Alarm-fires (see BEACON), the Semaphore (q. v.), and the Signals (q. v.) used at sea, are among the earlier forms of telegraph. But all other agents are now thrown into the shade by the Electric Telegraph. It has been reserved for our own day to develop into practical use the capabilities of electricity and magnetism as a means of distant communication; although in earlier times, the possibility of such a use of this natural power has been frequently suggested. The public use of the electric telegraph dates not earlier than 1846; but the idea that magnetism could be applied for distant communication is at least two centuries and a half old. Galileo, in one of his dialogues on the rival astronomical systems written in 1632, puts in the mouth of one of his speakers, a reference to a secret art, by which, through the sympathy of a magnetic needle, it would be possible to converse across a space of two or three thousand miles. In 1753, a letter appeared in the *Scots Magazine*, bearing the initials C. M., and headed 'An Expeditious Method of Conveying Intelligence,' in which we must recognize the first perception of the uses to which telegraphy might be put. This interesting letter starts with the remark that it 'is well known to all who are conversant in electric experiments, that the electric power may be propagated along a small wire from one place to another without being sensibly abated by the length of its progress;' and it goes on to describe an arrangement of wires corresponding in number to the letters of the alphabet, to be fixed in glass or jewellers' cement at intervals of 20 yards, and to convey, from an electric machine or rubber, a current which would lift each letter, 'marked on bits of paper, or other substance that might be light enough' to rise to the electrified ball which formed the terminal of each wire. The apparatus proposed is crude and clumsy, yet we can hardly fail to recognize, in the letter of this Renfrew man, the full appreciation of what the electric telegraph might become.

From a period shortly anterior to the date of the letter in the *Scots Magazine*, down to 1837, a large number of proposals, more or less ingenious, are on record. The space at our command will not permit us to describe all those inventions, or to enter upon the much vexed question as to who is entitled to the name of inventor of the electric telegraph. We must be content to furnish a description of the more important instruments in use, some statistics of the more recent history of telegraphy generally in this country, and a notice of the progress of submarine telegraphy. In our description of instruments, &c., we shall assume the reader to be familiar with the chief facts of GALVANISM (q. v.) and electro-magnetism (see MAGNETISM).

Telegraph instruments may be classed under two heads, namely, those which record the signals, and those which only give passing signals to the observer or listener. Among the former are several kinds, namely, those giving a record in arbitrary signs (*i.e.*, in the dots and dashes of the Morse alphabet); those which print in ordinary characters, such as the Hughes type-printing instrument; and lastly, a class of instruments giving a *fac-simile* of the message. The latter two classes are not much used, and the number of Hughes instruments in use in this country has somewhat decreased. The great bulk of the telegraphing of the world is done either by the Morse printer, or by the non-recording instruments; and to those we shall therefore devote the major part of our description.

The Morse.—The leading principle in the Morse and other allied instruments is, that by the depression of a key or other method, an electric circuit is 'closed' or completed, and a signal is transmitted along the wire to the distant station, where, on its arrival, it reproduces the signal by the action of an electro-magnet or otherwise. Electrically, the Morse consists of the transmitting key (fig. 2) and the electro-magnet and armature (fig. 1); while mechanically, it consists of a lever, with circular

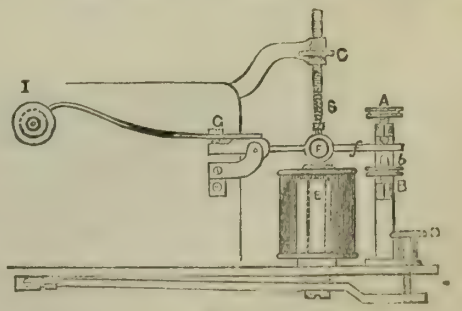

Fig. 1.

wheel or disc, attached to the armature, and a clock-work arrangement, by which the paper tape to be printed upon is carried forward under the disc. Fig. 1 represents the electro-magnet and armature by which signals are received. On the current being received from the distant station, it traverses the coils of the

electro-magnet E, and the armature F. is drawn down by the action of the current. A and B are screws for regulating the play of the armature, and of the inking-disc I, at the other end of the lever. The instrument clerk is first required to adjust B so that the upper edge of the disc shall press gently against the paper tape (which is not shown in the engraving) and the screw A, so that the under surface of the disc shall dip into the ink-well or reservoir (likewise omitted in the diagram). B having been adjusted, the screw D is turned so that when the brass stop *f* rests upon the stud *b*, the poles of the magnet shall clear the armature without actually touching it. A thin streak of light should be seen between the armature and the poles. Screw C is used to adjust the spiral spring above, by which, on the cessation of the electric current, the armature is drawn back and the disc ceases to mark the paper.

In the first Morse instruments the marks were made on the paper with a pointed style (the instrument being thus known as the *embosser*); but by the invention of the ink-writing arrangement of Siemens, which we are now considering, the legibility and permanence of the record were secured, besides the advantage that a very light current will serve to make the marks. The case containing the clock-work, the arrangement of wheels by which the paper tape is unwound and carried forward, and the switch, by which the running of the tape is stopped, are not shown in the figure. The passage of a current draws down the armature, and elevates the disc, causing a straight mark on the tape so long as the current flows. When it ceases, the spring S. draws back the armature as already described, and the mark is discontinued. Thus the duration of the current determines the nature of the mark, a momentary passage causing a dot, a longer depression of the key a dash; and as the alphabet invented by Professor Morse consists of dots or dashes, or a combination of the two, the above figure and explanation disclose the whole mystery of this system of telegraphy to those who have mastered the phenomena of electricity.

The Morse Alphabet.—Before going further, the details of this alphabet, universally recognized as a masterpiece of cryptography, may be given. The signals, as given below, are arranged in the groups, and accompanied by the mnemonic phrases, adopted by the British Post-office when, in 1870, the transfer of the telegraphs to the government rendered necessary the rapid training of thousands of telegraphists throughout the kingdom:

Group 1.		Group 2.	
.	E, Earwigs	—	T, Turnips
. .	I, infest	— —	M, make
. . .	S, summer	— — —	O, oxen
. . . .	H, houses.	— — — —	Ch, cheerful.
Group 3.		**Group 4.**	
. —	A, A	— .	N, No
. — —	W, wet	— . .	D, difficulty
. — — —	J, jacket's	— . . .	B, baffles
. . —	U, uncomfortable,	— — .	G, great
. . . —	V, very!	— — . .	Z, zeal.
Group 5.		**Group 6.**	
. — .	R, Remember!	— . —	K, kindness
. — . .	L, law	— . — .	C, conciliates
. — — .	P, preserves	— . — —	Y, youth
. . — .	F, freedom.	— . . —	X, extremely
		— — . —	Q, quickly.

The arrangement for the numerals is equally ingenious. Each figure is represented by five signals, thus:

1, . — — — —	6, — . . . .
2, . . — — —	7, — — . . .
3, . . . — —	8, — — — . .
4, ... —	9, — — — — .
5, ...	0, — — — — —

These are the numerals printed long, but on busy circuits expert clerks adopt the practice of 'sending short,' omitting all after the first dash in 1, 2, and 3, four of the dots in 5, and all before the last dash in 7, 8, 9, and 0. It is stated that Prof. Morse founded his alphabet upon information given him by his brother, a journalist, as to the numerical relation of the letters in the English alphabet, the simplest signal (a dot) being given to E, and the next simplest (a dash) to T, those letters occurring most frequently in our language.

The Transmitting Key.—The 'key' or hammer by which signals are transmitted from the operator at the sending office, is shown in fig. 2, in one of its earliest and most simple forms. The lever *l, l* turns on its axis A, and has on its under side two platinum nipples, *m* and *n*. L is the line-wire, connected with the axis; E, the 'earth'-wire (passing through the Morse on its way to earth, and producing its signal there); and C, a wire connecting the stud *a* with the battery. As the key stands in the figure, it is in the position to receive a current from the distant station, the course of the current being L, A, *l*, *n*, *b*, and thence to the electro-magnet of the Morse *en route* to earth. When it is desired to send a

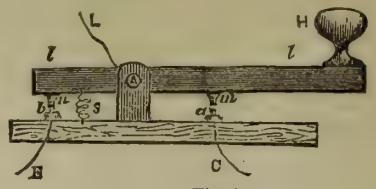

Fig. 2.

current, the handle H is depressed, and the current, generated in the Battery, then comes by the wire C, and passing through *a*, *m*, and A, proceeds by the line-wire to the distant station. Various modifications of this key are in existence, but in all the principle remains the same, that the electric circuit is closed or completed by the depression of the key. The length of time during which the handle is depressed, determines the length of the mark produced at the other end. Thus, if the clerk presses down the handle while he says, 'one—one two three,' the ink-disc at the other end gives the mark · — (dot dash) or the letter A, and so on through the various letters of the alphabet.

The Battery.—For the generation of power in the electric telegraph, Daniell's batteries (see GALVANISM) are chiefly employed in this country. Various forms of the Bunsen battery are also used, especially on the continent. The power employed varies with the length of line, the condition of the wires as regards insulation, and the nature of the instruments used.

The Circuit.—The mode of joining up two stations by means of earth-wires, batteries, instruments, and line-wires, is shown in fig. 3. Assuming S and S 1 to be telegraph stations, P and P 1 are the 'earth'-plates (see subsequent paragraph), B and B 1 the batteries, *n* and *n* 1 the electro-magnets and armatures, and *b*, *k*, *g*, the transmitting keys and galvanometers. L, L show the line-wire, supported on poles and insulated. The key at station S is shown depressed, so that a current of electricity may be supposed to be passing from the battery B through the key and galvanometer along the line-wire, and thence through *k* 1 and *n* 1 to the earth-plate P 1. Supposing, then, that the clerk at S desires to send a message to S 1, he depresses the key *k* several times so as

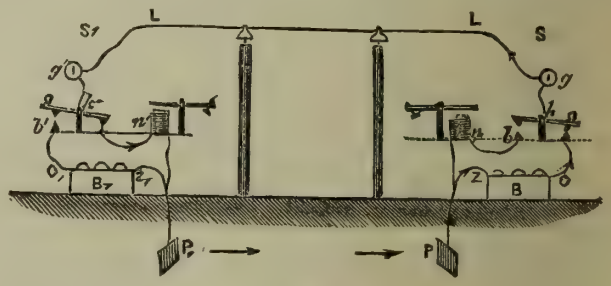

Fig. 3

to send a series of dots and dashes corresponding to the name (or rather the code signal representing the name) of the distant station. The attention of the clerk being gained by the clicking of the Morse, he turns the switch to set his paper tape in motion, gives the signal that he is ready, and the message is then sent.

The Line.—From fig. 3, some idea may be gained as to the mode of carrying a wire or series of wires over posts, these posts being carried along the sides of a road or railway. In towns, wires are carried 'over-house,' or by underground pipes, the wires in the latter case being insulated by means of a guttapercha or other suitable covering. The subterranean method is being applied to extended lines, especially in Germany, and is found to answer as well as the overhead system, while it avoids many of the casualties to which the latter is liable. In pole and over-house lines, the wires are kept from each other and from contact with the earth by insulators of various kinds. White porcelain and brown stoneware are the chief materials used. The former, when of good quality, well glazed, and well burned, is perhaps the most perfect of all insulating materials, and does not deteriorate with age.

The fewer the poles are in number on which the wires are suspended, the better is the insulation, and the less the cost, but the liability to accident is probably greater. The number of poles used varies from 16 to 30 per mile, and is governed by the number of wires carried, the configuration of the track, and other considerations. On road lines, the number of poles is generally larger than in the case of telegraphs carried alongside railways, the greater levelness and straightness of the latter reducing the number of supports required. The wire chiefly used for inland tele-

graph purposes is of iron, galvanized, and of No. 8 (⅛ inch) gauge. The conductivity of a wire increases in the ratio of the square of its diameter (the resistance decreasing in the inverse ratio), and the advantage of using a thicker wire on the longer lines is thus seen. No. 4 wire is, for this reason, used on some of the longer lines.

The Earth—Earth Currents.—Mention has been made of the 'earth,' in the preceding description. This is the technical expression used in relation to the fact discovered by Steinheil in 1838, that the earth itself serves the purpose of completing the circuit, and renders the employment of a second or return wire unnecessary. The 'earth' may consist of a buried plate of metal connected with the battery or line-wire, and of sufficient surface to afford the necessary diffusion. The gas or water pipes of a town form excellent 'earths,' care being taken that the connection is made with the pipe itself, and not with a branch, where a badly made joint might spoil the connection. Where dissimilar 'earths' are in use, as for instance, a copper plate at one end, and an iron pipe at the other, a *quasi* battery is created, and vexatious currents pass along the line. Hence the 'earths' on a circuit should be made alike.

The earth, being regarded as a large reservoir of electricity, offers no sensible resistance to the passage of the current, in the same way as the ocean would receive or supply at any point an indefinite quantity of water. While this quality of the earth is one of the most valuable aids to telegraphy (reducing so materially the cost of wire erection), it presents at times those embarrassing interruptions known as *earth currents*. These currents, at all times unwelcome visitors to a telegraph office, are very variable, changing rapidly at times from positive to negative, altering their direction with the hour of the day, and leaving one circuit to appear on another in a manner not explainable. The lines most liable to such disturbances are those running N.E. and S.W.; that is, connecting places separated in a straight line in those directions, and without reference to the actual direction of the wires. The easiest remedy for earth currents, when they are of sufficient strength to affect the lines, is to dispense with the earth connection, and revert to the original plan of using two wires. Thus between places where there are two wires, both may be disconnected from 'earth,' and used as a complete metallic circuit. Another remedy has been found in extending the circuit by joining to it a further wire, the terminal point of which lies beyond the direction or line in which the earth current is flowing. We must refer to the larger treatises on telegraphy for information regarding lateral induction, the velocity of electric discharge, the tests for resistance, insulation, &c., and also for notices of some of the less prominent pieces of apparatus now found in the instrument-room of the electrician.

The Relay.—We now proceed to notice several methods by which the transmission of signals is facilitated or accelerated. First among those may be placed the *relay*, of which an excellent form is shown in figs. 4 and 5. This is Siemen's Polarized Relay,

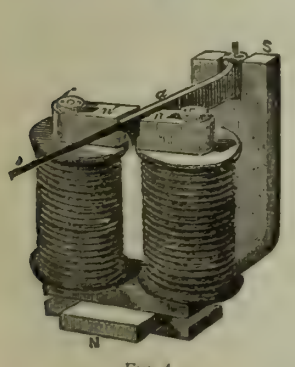

Fig. 4

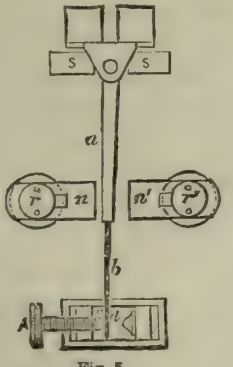

Fig. 5.

now in very extensive use in this country. In the previous description of the Morse, we have assumed the instrument to be worked directly by the current sent along the line. On long circuits, however, direct working could only be accomplished by great battery power, as, owing to inevitable loss by leakage, a current loses greatly before it reaches its destination. It is found to be a much better arrangement to have the instrument worked by a 'local current,' derived from a local battery at the receiving station. The mode by which this is accomplished will be seen from the diagrams. In the figures, N S is a hard steel permanent magnet, whose south end S has a slit, in which the soft iron armature, *a*, is pivoted. To this armature a thin aluminium tongue, *b*, is attached, which, by making contact at the point *c* (fig. 5), completes the local circuit. To the north end, N, of the permanent magnet the soft iron cores of the electro-magnet are fixed, as shown in the sketch. When the armature is equidistant from the poles of the electro-magnet, it is equally attracted by both; but if it be brought nearer to one than to the other, it will be held there, because it is under the influence of a more powerfully attracting force. Since the relative distance between the armature and the two pole-pieces may be increased at will, the attraction between either pole and the armature may be regulated with any degree of nicety. The electrical contacts for the local circuit are seen in fig. 5, which is shown with the local circuit completed.

When two stations far apart are to be connected by telegraph, it is usual to transmit the signal to a half-way station, and thence to retransmit it to its destination. The retransmission is not effected by manipulative skill, but by mechanical contrivance, so that, while the half-way station may read the message sent, no time is lost in the transmission. This is effected by making the intermediate instrument act as a relay in transmitting a message to the next station. The system, to be fully explained, would require more detail than we can here give to it. We shall only show how it is effected, leaving out of account how all the stations can communicate as in one circuit. The current, C_1 (fig. 6), from the sending-station enters the coil M, and goes thence to earth P, and returns as shown by arrow C_1. The instrument may record or not as required, but its doing so in no way interferes with translation. The copper pole C, of the battery CZ, is connected with the lever *l l'* of the register, and the zinc pole is to earth. When the lever is drawn down by the current C_1, it strikes against the point at the top of the pillar *p*, that checks its motion. The pillar *p* is joined to line L_2, running to the further station, and when the lever falls, a second circuit—viz., that of the battery CZ—is closed, in which C, the lever, the pillar, L_2, the further station, the earth, P, and Z are all included. Thus, as *l l'* prints at the intermediate station, it at the same time sends a new printing-current to the next. When it ceases to print, so does the instrument at the distant station.

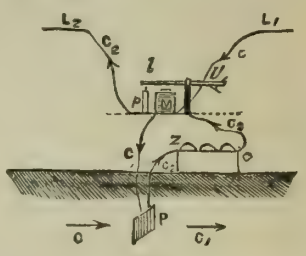

Fig. 6.

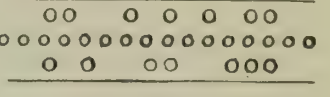
Wheatstone's Automatic Transmitter.—The speed of the ordinary Morse instrument is limited to the rapidity with which the hand of the operator can move the key, so as to preserve the proper spacing between the marks at the receiving instrument. We are indebted to Sir Charles Wheatstone for an apparatus which trebles, and in some cases quadruples the carrying capacity of a wire, securing, at the same time, mechanical accuracy in the relative size of the dots, dashes, spaces, &c. To effect this, three different instruments are required: First, there is a perforator, by which holes are punched in a paper slip to correspond with the signals required. The operator strikes three discs, the central one producing a central hole, which is of no avail electrically, only carrying forward the paper; the left-hand disc producing two holes, directly opposite to each other, on the sides of this central row; and that on the right producing two holes, placed diagonally to each other. The passage of the electric current is regulated by the position of the outer holes. Those opposite each other admit of a momentary passage of the current through the 'transmitter'—used in sending the message—while the holes diagonally placed produce a lengthened mark, corresponding to the dash. The following diagram represents the word 'and,' as shown on the punched slip:



As printed at the other end, this reads:

. — — . — . .
a n d.

The third portion of this instrument is the 'receiver,' in which the currents sent by the action of the punched slips in the transmitter are reproduced in the dots and dashes of the Morse code—the printing being, moreover, done with a mathematical accuracy which keying by hand cannot attain.

The speed of transmission depends on the length of line and state of the atmosphere; but the movement of the clock-work, both of transmitter and receiver, is capable of adjustment to any speed below 120 words per minute. When the Post-office took possession of the telegraphs in this country, the Wheatstone automatic instrument was in use at only four stations in the kingdom. It has since come into extended use; and one of its most successful applications is in the simultaneous transmission of news from London to a large number of towns. The punched ribbon is carried from one transmitter to the other, the circuit to Birmingham, Manchester, and Liverpool (on which the highest speed is attained) sending it first, and from that instrument it passes to

several others, each serving several towns. The adjustment of 'resistance,' by which a message is run off simultaneously at Edinburgh, Glasgow, Dundee, and Aberdeen by one sending from London (and so through the various transmitters, where this system of 'express news circuits' is adopted), forms one of the most interesting objects of study in the practical working of the telegraph in this kingdom. By combining the automatic transmission with Bain's principle of producing marks on chemically prepared paper, an American inventor has accomplished still higher speed, the lever action of the inkling disc (fig. 1) being saved.

Other Instruments.—All that has been said as to the battery, the earth insulation, &c., is applicable to nearly every instrument now in use; the exception being several magneto-electric instruments, such as Wheatstone's 'ABC,' in which the use of a battery is dispensed with, power being generated by two bobbins coiled upon an armature rotating continuously over the two poles of a permanent magnet. On the upper surface of this instrument is seen a circle of buttons corresponding to the letters of the alphabet, by means of which levers, arranged vertically in a circle, may be pressed down. These levers press a pitch-chain into a series of indentations on the periphery of a metal disc, the chain having sufficient slack, so that, when a second lever is depressed, the first must be raised. A series of currents, corresponding to the number of letters between each lever pressed down, is sent into the line, and operating on two little bent magnets, moves forward a ratchet wheel, having a pointer on the same axis which shows the letter on a dial card. In this way the message is spelled out letter by letter, and as the instrument gives not an arbitrary sign, but the letter itself, it is much used in private telegraphs and for the smaller post-offices throughout the kingdom. The non-recording instrument most used in this country (excluding private telegraphs) is the single-needle instrument of Cooke and Wheatstone. It consists of an upright galvanometer, with astatic needles, one of which moves within the coil, and the other upon the front of the dial. The needles are loaded at the lower end, to maintain them perpendicular when no current is passing. The instrument is worked by means of two keys, like those of a piano, a deflection of the needle to right or left being effected by depressing one or other of the keys. The signal is shown both on the sending and receiving instrument. The Morse alphabet is used, a deflection to the left corresponding to the dot, and one to the right representing the dash.

Acoustic Telegraphy.—Before the introduction of high-speed automatic instruments for the more important circuits, expert telegraphists in many cases dispensed with the reading of the printed slip, reading by the sound, which, by long practice, became a language perfectly intelligible to them. The great advantage of this was, that the use of the eye was obtained exclusively for the task of writing down the message. In Sir Charles Bright's 'bell' instrument, most admirable results, in point of speed, have been attained. The bells, different in sound, are placed at the two sides of an upright instrument, so that the clerk, bending forward to write, may concentrate his attention on that duty, translating in his mind the tinkle of the hammers as they ring out their message. The bells are now worked in the Morse code—the left bell a dot, and the right bell a dash; but when first introduced, the instrument had a code of its own, based on the desire to complete each letter as much as possible on one bell. A simpler acoustic telegraph has been brought into use in America (hence called the 'American Sounder') and in this country. This instrument is, shortly stated, the Morse without its wheel-work and ink-printing apparatus; and its whole construction is shown in fig. 1, omitting the inking disc. The use of the 'Sounder' has greatly increased in this country owing to its cheapness and efficiency. For a description of the type-printing and *fac-simile* instruments, on which great advances have been made of late years, we must refer our readers to the larger treatises on the telegraph and its history.

Duplex Working.—The fact that two currents may be sent simultaneously (one from each end) has been long recognized by electricians, but the principle of the duplex was revived and patented by Stearns, an American, in 1872. At first the duplex working was only tried on short circuits of 40 to 60 miles; but it has now become a matter of daily use on every busy circuit, long or short, both in this country and abroad. The principle of the duplex system is, that the current sent on the depression of the key is divided into two parts, one-half being carried through one pair of coils in a differential galvanometer to the line, and the other half through the other pair of coils to a resistance coil, and thus to earth. The resistance of the latter is made exactly equal to that of the line-wire, and the instrument of the sender being so placed that this divided current presses equally in each direction, this instrument remains unaffected, while the armature at the other end responds to the signal sent. At the same time, a telegraphist at the other end is sending a current, which is divided in like manner, and leaves his own instrument unaffected while operating on the armature of the first instrument. The two currents on the line-wire assist or oppose each other in such a way as to affect the equilibrium in the differential galvanometer, but each operates only on the distant instrument. Duplex-working led to *diplex*, that is, two messages passing over a wire in the same direction at once, and to this has followed quadruplex and multiplex telegraphy. Quadruplex working was first perfected in 1876 by Prescott, Edison, and Gerritt Smith, but the possibility of its being accomplished was suggested by Stark of Vienna, in 1855. It was introduced into Britain as a practical branch in 1878, and is now used from London to Liverpool, Dublin, and other towns. An illustration of the value of these additions to the wire power is afforded by a wire from Chicago to Pittsburg, 550 miles, which is quadruplexed, and at Pittsburg branches off in two duplex circuits to Baltimore and Philadelphia, giving Chicago duplex communication with these two places. In the same way Middlesborough and West Hartlepool have been duplexed to London, on separate wires as far as Leeds, and quadruplex on one wire thence to London.

Multiplex Telegraphy and 'Phantom' Circuits.—The most original feature of the telegraph section of the Paris Exhibition of 1878, was the Harmonic Telegraph of Haskins and Gray, based on principles laid down by Cromwell Varley in 1870. In one application it occupies a place midway between duplex and multiplex telegraphy, namely in the 'way duplex,' or as it was felicitously termed by the late Mr. Orton, the 'phantom circuit.' A wire may be occupied by the ordinary business of a series of intermediate offices, while there may be superimposed on that a through traffic (which can be duplexed) between the terminal stations. Thus between Chicago and Dubuque, a wire provides for seventeen intermediate stations, working ordinary Morse sounders, while the harmonic telegraph (the principle of whose action is vibratory currents sent and received by musical forks tuned in unison) works between the terminals. By an extension of this principle we have the multiplex telegraph, each fork taking off at the receiving end those vibrations corresponding to its own tone.

The Electric Pen.—Amidst many endeavors to introduce an autographic telegraph, that of Cowper, made public in 1879, is the most successful. It has the drawback of requiring two wires, but is so beautiful in its action as to deserve notice here. Two series of resistances are ranged like the letter L, one series affected by lateral, the other by the up-and-down motion of the sender's pen. At the other end, a siphon recorder moves in accordance with the currents thus sent, giving on a moving slip of paper an exact *fac-simile* of the writing or other marks of the person sending the message.

Statistics.—In Great Britain, the first public introduction of telegraphy was made in 1846 by the Electric and International Telegraph Company. Subsequently, the British and Irish Magnetic Company was established, and afterwards the United Kingdom Company, the last named being started on the footing of a low uniform rate, but eventually yielding to the opposition of the other companies, and adopting a sliding scale of rates. The charges were from 1s. to 6s., according to distance, for a message of 20 words. Besides these companies, there were the London District Company, the Universal Private Telegraph Company (which established a series of public telegraphs, connecting Glasgow with places on the west coast of Scotland), and a large number of railway companies, carrying messages between their own stations, besides acting as agents to collect business for the other companies. In 1868 and 1869, after some agitation of the question, acts were passed transferring the property of the telegraph companies to the Post-office, and giving that department a monopoly in the conduct of telegraph business within the kingdom. The task set before the Post-office was to reduce and simplify the charges, to separate entirely the public wires from wires used for railway purposes, to extend the telegraph to outlying places and to business parts of towns, and to establish free trade in press telegraphy—the meaning of the latter being that, instead of collecting and supplying news as the companies had done, the department should only arrange to transmit news, at specified rates, for all comers, leaving the newspapers to make their own arrangements for obtaining information. The great progress of telegraphy in the hands of the Postal Telegraphs Department is one of the social features of the time. Including a large number of new offices prepared for opening on the occasion, the Post-office started in 1870 with 1007 telegraph stations, with about 1900 railway stations receiving messages. In 1880 the number of offices belonging to the Post-office was 3924, making, when the railway stations are added, a total of 5331 offices. The railway offices only take in from the public 7 per cent. of the messages sent. The number of telegraphic messages sent in the year 1880–81 was 29,966,965.

The mileage of telegraphs increased between 1870 and 1880 from 5651 miles (48,990 miles of wire) to 23,156 (100,851 of wire), besides about 6000 miles of private wires, for which rents are paid to the department. The number of messages before 1870 was estimated as reaching six millions annually, and the following gives the totals for three years since the telegraphs passed into the hands of the Post-office.

	No. of Messages.	No. of Offices Open.	Weekly Average for each Office.
Year ended March 1871,	9,850,177	3926	46
" " 1873.	15,535,780	5540	53
" " 1878.	22,171,783	5311	80

These statistics show that the growth of business had been so large as to raise the weekly average over the whole number of offices, the closing of many small railway stations also helping this result. So far as the cost to the public is concerned, it is shown that, while under the *régime* of the companies the cost per message averaged 2s. 1½d., the cost under the Post-office reaches an average of under 1s. 1d., per message. Writing in May 1872, Mr. Scudamore, under whose direction the transfer and extension of the telegraph system was conducted, says: 'If the messages of the current financial year were to be paid for at the old tariff, they would cost the senders at least £400,000 more than they will cost.' The revenue for 1879—1880 was £1,469,795, including in this private-wire rentals, newspaper special wires, &c. The capital invested in the undertaking amounts to about ten millions sterling. The cost of working in 1877—1878 was £1,164,131: the staff consisting of 406 persons in the central control of the system (secretary's and accounting offices); 650 in the engineering department (for maintenance and extension of the system); a staff of 1770 in the central office at London; and the services of postmasters, telegraphists, &c., throughout the kingdom, making a total of above 11,400 persons engaged in the service. Of these, 4981 were messengers engaged in the delivery of messages, the larger portion of whom were supplied with uniform.

In addition to electric means of communication, the Post-office uses pneumatic tubes in London and other cities, to connect the larger branch offices with the principal station in each case. As those tubes, although forming an interesting branch of the apparatus, are not, strictly speaking, electrical, we must refer to other sources for information as to their construction, mode of working, power used, &c. The result of the transfer from private hands to the control of the government may be summed up in saying that for efficiency, comprehensiveness, and public appreciation, the telegraph system in Great Britain is now second to none in the world. The continent of Europe forms one vast network of telegraph lines. By means of submarine cables (as afterwards noticed), the offices in this country are connected with all the four continents, while recent extensions have brought the Australian colonies also into connection with the other sections of the globe. While each kingdom fixes its own internal tariffs and regulations, the rules for the interchange and transmission of telegraph messages between the various countries of the world, are regulated by telegraph conventions agreed to at Paris, Vienna, Rome, St. Petersburg, and London (the last named being held in 1879); and all official intimations in connection with international telegraphy are issued from a central bureau in Berne, Switzerland. To the mountain republic the world is indebted, not only for the example of an excellent and cheap internal system, but for the suggestion of this central administration, where all international matters are conducted. In France and Belgium internal telegraph arrangements are complete and cheap; while the United States of America for many years held a place far in advance of other countries in the ordinary every-day use of its great telegraph organizations. Perhaps the most striking instance of telegraph enterprise is that by which the daily newspapers of San Francisco are enabled to give, by means of a line of telegraph carried over the Rocky Mountains (on the line of the Central Pacific and Union Pacific Railroads), not only the news from New York, but the parliamentary news from London, the prices of all the continental exchanges, and quotations from Calcutta and China, of the previous day.

Submarine Telegraphy.—From the year 1850, when a copper wire insulated with gutta-percha, submerged between Dover and Calais, continued in use for one day, the progress of submarine telegraphy has been as remarkable as that of telegraphy on *terra firma*. Fig. 7 gives a view (full-size) of the Malta-Alexandria cable, laid in 1861, and continued in use till 1872, when, from repeated breakages in shallow water, its use was discarded. The different layers are peeled off to show the construction. C is a strand of seven copper wires; G, three layers of gutta-percha; H, a serving of tarred yarn; and I, eighteen iron wires constituting the sheathing. This was the first long cable successfully laid (its total length, in three sections, being 1331 miles); and it was also the first properly tested under water before being laid, and carefully constructed with constant watchfulness as to its electrical and mechanical conditions. This cable was thrown out of use because the chafing it underwent in shallow water made it too expensive in maintenance. So far as construction goes, it corresponds very nearly with Sir James Anderson's typical 'successful iron-covered cable.' With careful testing and supervision, and with the weight of cable, &c., duly proportioned to the strain, &c., a cable forms a permanent property of much value. A new form of cable, with lead as the conductor, has been suggested. In 1877, the task of duplexing a submarine cable was accomplished by Muirhead on the Aden and Bombay cable of the Eastern Telegraph Company, and the 'artificial line' or balance has been since applied successfully to other cables, including two crossing the Atlantic. In view of the enormous cost of submarine telegraphy, the attainment of a means by which the carrying capacity of a cable is nearly doubled, is of vast importance.

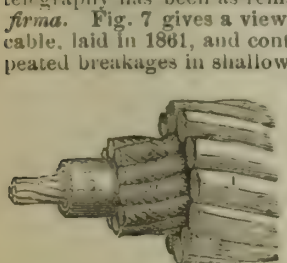


Fig. 7.

In 1877, the Marseilles-Algiers cable, belonging to the French system, was duplexed by M. Ailhaud. The *Journal Télégraphique* gave in 1877 a list of 149 cables belonging to companies, and 420 belonging to government systems, existing at that date. In point of number, Norway stood first, with 193 cables, but the total length of these is only 233 nautical miles. The total length of the 420 government cables was 4442 nautical miles, of which Britain possessed 49, measuring 1338 miles. The longest of these (excluding cables to the continent) is to Guernsey 70, and to Shetland 63 miles. The company cables (of which 96 per cent. had their administration in London) measured 59,547 nautical miles. The longest cable is that from France to America, 2585 nautical miles, and the largest organization that of the Eastern and Eastern Extension Companies, embracing 48 cables of a total length of 21,883 nautical miles, to which since 1876 several thousand miles have been added in new routes or duplicate cables. In 1879, Great Britain was connected with Europe by eighteen cables, and with Ireland by five cables. From Europe to America seven cables crossed the Atlantic (five from Ireland, one from France, and one from Portugal to Brazil). A cable from Nagasaki to Shanghai joins the internal system of Japan with the outer world; while by cables of 557 miles from Singapore to Batavia, and 1082 miles from Java to Australia, and by the East African cable from the Cape to Aden, the distant colonies are brought into the telegraph system of the world. In 1882 was completed a submarine line, 3100 miles in length, between Lima and Vera Cruz in Mexico, crossing the isthmus of Tehuantepec by a land line of 220 miles; it thus connects the South American Pacific coast with the United States.

See works on *Practical Telegraphy* by Culley, Sabine, Preece and Siveright, &c.; *Journal of the Society of Telegraph Engineers;* Sir James Anderson's Lecture before the Statistical Society, London, June 1872; Mr. Scudamore's Reports to the Postmaster-General, 1870 and 1872; Estimates for the telegraph service, laid annually before Parliament; &c.

TELE'MACHUS, son of Odysseus (see ULYSSES) and Penelope (q. v.), was an infant when his father left home to join in the war against Troy, but during the latter's long absence of about 20 years grew into manhood. At the instigation and under the guidance of Athene (Minerva), who had assumed the appearance of Mentes (commonly known as Mentor, Lat. 'the thoughtful one'), king of the Taphians, his father's dearest friend, T. set out in search of his long-lost sire, after having vainly endeavored to eject his mother's troublesome suitors from the house. Having visited Pylos and Sparta, at both of which places he was most hospitably entertained, T. returned home to Ithaca, where he found his father in the guise of a beggar, living with the swineherd Eumæus. After mutual recognition, father and son proceeded to slay the suitors. In modern times, T. is known chiefly as the hero of Fénelon's (q. v.) romance, *Télémaque*, once very popular as a school-book.

TELEO'LOGY, the doctrine of ends, is derived from the Greek *telos*, an end, a word brought into philosophic discussion by Aristotle. The idea of an end entered into the Aristotelian conception of physical science, but more properly into ethical science or morality. All the ancient sytems of morality, from Socrates downward, correctly regarded it as a *practical* science; they started with the inquiry, 'What is the proper and final end of all human conduct?' and the answer given by each school was the characteristic doctrine of the school. Aristotle answered, 'Happiness, in a peculiar sense;' the Stoics said, 'A regard to the whole universe of being;' the Epicureans, 'Pleasure and the absence of pain.' John Stuart Mill, in the concluding chapter of his *Logic*, entitled, 'The Logic of Practice, or Art; including Morality and Polity,' adopts the ancient point of view, and observes that there should be a science of ends, or a reasoned statement of the final purpose of all human action; for this science he suggests the name Teleology, remarking that it corresponds to what the Germans call the practical reason. There would be comprehended under it, the art of living or happiness, taste or the beautiful, morality, and politics. See CIVILIZATION. The word Teleology is applied to the argument from design in proof of the Deity. This is in keep-

ing with Aristotle's employment of the word in physics. When a natural philosopher assigns the purpose or end of any natural arrangement, as the offensive or defensive weapons of an animal, he is said to give a teleological explanation.

TELEOSAU'RUS, a genus of fossil crocodiles, the remains of which occur in the Oolitic rocks. They are found associated with marine fossils, and the peculiar modification of their skeleton seems to have specially fitted them for an aquatic life. Both surfaces of the vertebræ were slightly concave, the hind-legs were large and strong, and the anterior portion of the body gradually tapered into the long and slender jaws, giving the animal the aspect of the gavial of the Ganges, only the jaws were more attenuated, and the nasal aperture, instead of being oblique, opened vertically on the truncated end of the upper mandible. The jaws were armed with numerous equal and slender teeth, slightly recurved, and admirably adapted for the capture of fishes, with which the Oolitic seas abounded. No less than twenty species have been described, and these present so many striking differences, that they have been arranged under six sub-genera.

TE'LEPHONE. This instrument is designed to convey sounds to a distance by means of electricity. In 1860, Reis of Frankfurt first recognized the principle of the T., using a membrane which, vibrating under the action of sound, caused pulsations of electricity to pass along the wire, and actuated the armature of an electro-magnet, which, mounted on a sounding-board, reproduced a sound corresponding in pitch and rhythm with the original. The quality of the sound was however entirely lost. There are several claimants for priority in the discovery of the principle of the articulating T., and the discoveries of Gray of Chicago, and Graham Bell, an Edinburgh gentleman resident in America, appear to have been nearly contemporaneous, and attained by different lines of study. The articulating T., of Bell, which was first shown at the Philadelphia Centennial Exhibition, is now of very simple construction. A small bar magnet, with a coil of wire round one end, is placed close behind a diaphragm of ferrotype, the whole being enclosed in a case furnished with a mouthpiece. Words spoken into the T. are reproduced faithfully on a similar instrument at great distances, and by the use of the Microphone (q. v.), the most minute sounds have been distinctly heard and even magnified. Many extraordinary results have been achieved in conveying and reproducing sounds, and self-caught sounds from 'induction' in the wires have produced interesting results. While the T. is already very largely used in America for domestic and business communication, it has been less successful in Britain, the busier lines increasing the difficulties arising from induction. Three requirements appear to be demanded to bring the T. into general use—namely, a simple and reliable call or *avertisseur*, an increase of the sound to render it unnecessary to hold the T. to the ear, and the removal of induction currents. Various methods for accomplishing each of these ends have been proposed, but the difficulties are not yet wholly overcome. A controversy exists whether the sounds in the receiving T. are vibratory or molecular, or a combination of both.

TELE'PHORUS, a genus of coleopterous insects, of the suborder *Pentamera*, and section *Serricornes*. The body is long, narrow, depressed, soft, and somwhat flexible. The species are numerous, and some of them abound in Britain in summer, chiefly in meadows and pastures. The larvæ dwell in moist earth, and devour small insects and their larvæ. The perfect insect feeds on similar food.

TELE'RPETON, a remarkable genus of fossil reptiles, the relics of which have been found in fine-grained whitish sandstone quarried at Cummingston, near Elgin. A single species, or rather a single specimen, is all that has as yet been detected. It exhibits the skeleton complete, with the exception of the termination of the tail, but the bones have disappeared, and left only the casts as dark-colored cavities in the pale gray rock. Nearly perfect casts of their form were taken by Dr. G. Mantell from these hollow casts. The impressions are so well defined as clearly to show that there were twenty-six vertebræ between the skull and the sacrum two sacral vertebræ, and the portion of the tail preserved on the slab consists of thirteen others. The ribs, of which there are twenty-one pair, are very slender; they are short near the head, but quickly lengthen as they leave it. The reptilian nature of this fossil is evident. By Dr. Mantell it was considered to be a batrachian, and described as *Telerpeton Elginense;* but Professor Owen has more correctly referred it to the lacertine type, because of the numerous ribs, the structure of the sacrum, and the form of the pelvis. He has named it *Leptopleuron lacertium.* It has been matter of debate whether the rocks in which the T. was found belong to the Old Red Sandstone measures or to the Trias.

TE'LESCOPE (Gr. *tele-skopos*, far-seeing) consists essentially of a lens or mirror, to form, within our reach, an image of a distant object; and a Microscope (q. v.), to examine this image in detail. Its invention is ascribed to various individuals living about the end of the 16th c.; but there is no doubt that Galilei (q. v.) was the first to apply it to any purpose other than the gratification of mere curiosity.

The space at our disposal will not allow of our entering into any minute details, so we propose to give, *first*, a general idea of the mode in which a telescope acts, in the course of which we shall incidentally show how the magnifying power and the brightness of the image depend on the dimensions of the various parts of the instrument; *second*, to point out the various causes of imperfection, which in all telescopes are unavoidable, and how these are reduced to as small an amount as possible; *third*, to mention the most important of the many forms which have been devised, and the processes by which these delicate instruments are practically constructed.

When a lens is employed, as in a camera obscura, to form an image of an object, as AB in fig. 1, the distance of the image from

Fig. 1.

the lens depends on the focal length of the lens, and also on the distance of the object. Practically, with telescopes, the distance of the image from the lens is, on account of the remoteness of the object, the focal length of the lens. Also the image of any point, A, of the object lies in the prolongation of the line joining A with the center, C, of the lens. Join AC, and produce it to *a*, C*a* being made equal to the focal length of the lens, *a* is the point at which the image of A is formed. Similarly at *b* the image of B is formed.

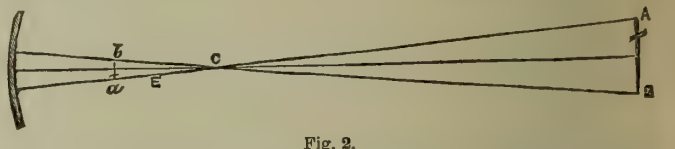

Fig. 2.

Thus the image is *inverted;* and, seen from C, the image and the object subtend equal angles, or look equally large. When a concave mirror forms an image, the effect is as in fig. 2, where C is now the center of the sphere of which the mirror is a portion. When the object, AB, is at a great distance, the image, *ab*, is *inverted*, and is formed half way between C and the mirror. As before, object and image subtend equal angles at C. In order to see these images, the eye must be placed at some such point as E in each of the figures.

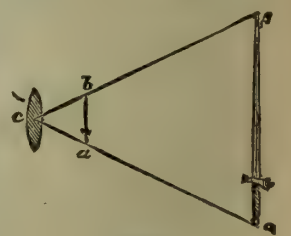

Fig. 3.

So much for the formation *within our reach* of an image of a distant body. We must next show the action of a lens when employed to magnify this image. When an object, as *ab* in fig. 3, is placed rather nearer to a lens than its focal length, rays which pass from the object through the lens appear to have come, not from the object, but from an enlarged image as $a\beta$, at a greater distance from the lens—but subtending, as before, the same angle at the center, *c*, of the lens. In practice, the lens is so adjusted as to form the image, $a\beta$, at a distance of about ten inches from *c*, in which case the eye sees it most distinctly, and the distance of *ab* from the lens is then (practically) the focal length of the lens.

We now combine the first and third diagrams, and we have the *Common Astronomical Telescope.* The magnifying power is obviously to be measured by the increase in the angle which is subtended by the image, $\alpha\beta$ (fig. 4), over that which is subtended by

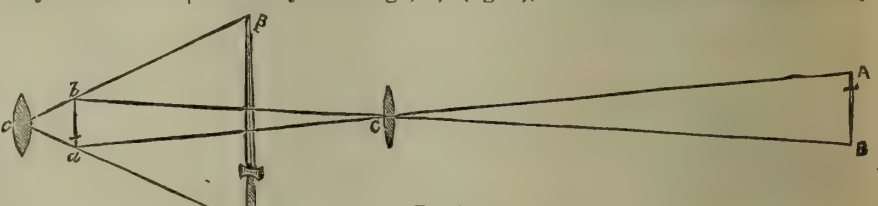

Fig. 4.

the object, AB. The angle at C is the measure of the apparent size of the object; that at *c*, of the apparent size of the image. And it is easy to see from the quadrilateral C*acb* in the figure that these angles are inversely as the sides C*a* and *ac*. (For instance, if C*a* have six times the length of *ac*, the angle at C will be only one-sixth of that at *c*.) Hence the magnifying power is to be

found by dividing the focal length of the object-lens by that of the eye-lens. In practice, the lenses are so mounted in tubes that their distance may be increased or diminished at pleasure. When the object, AB, comes nearer the observer, its image, *ab*, is formed *further* from the lens C. Hence, for near objects, the telescope requires to be pulled out. Again, the distance of most distinct vision differs for different people, so that even when AB is at a fixed distance, short-sighted and long-sighted eyes require the eye-lens to be removed from, or advanced to, *ab*, so that for each eye $\alpha\beta$ may be formed at the distance at which it can be most distinctly seen.

To estimate the relative brightness of the image and object, suppose, for simplicity, all the light which enters the telescope from the object to reach the eye. Then the quantity of light which enters the eye from the image, is greater than that which would enter the unaided eye from the object, in the ratio of the aperture of the object-glass, C, to the apertue of the pupil of the eye. But it is spread over a magnified image. If the image be as much larger than the object as the object-glass is larger than the pupil of the eye, the object and image will appear equally bright. Taking the aperture of the pupil as $\frac{1}{10}$th inch, the object-lens would require an aperture of 10 inches, with a magnifying power of 100 times, in order that brightness should not be lost. Practically, the most formidable difficulty in attaining very high magnifying powers, is that due to the enormous sizes of lenses and mirrors which are required to give the necessary brightness to the enlarged image. It is easy to see that it is impossible to render the final image brighter than the object, by any increase of dimensions in the object-lens.

After what we have said about the common astronomical telescope, the reader will have no difficulty, from a combination of figures 2 and 3, in understanding the construction of the Newtonian or Herschelian reflecting telescope.

We proceed to the second part of our proposed scheme of treatment of the subject, viz., the unavoidable imperfections of the telescope, and their reduction to a minimum.

In the first place, then, even with a mirror—where we are not annoyed by the breaking up of white light into its component colors, since the Law of Reflection (q. v.) is the same for all rays—it is impossible to form a perfectly sharp image of more than *one* definite point at a time. In order to do even this, the mirror must be formed as part of the prolate spheroid produced by the rotation, about its longer axis, of an Ellipse (q. v.), one of whose foci is the object-point, the other the image. If the object-point be, like a star, practically at an infinite distance, the requisite form of the mirror is that formed by the rotation of a Parabola (q. v.) about its axis. The axis of the mirror must then be directed to the object-point, and all rays from it will, after reflection, pass accurately through the focus. But this is not strictly true for any other object-point in the field of view, although so nearly true that no inconvenience is practically found to result from it. But, if the mirror used be part of a sphere, no point can be found such that rays diverging from it shall all be brought after reflection accurately to one point of the image; and this defect, called *Spherical Aberration*, increases proportionally to the surface of the mirror; so that by increasing that surface, for the attainment of brightness, we increase proportionally the indistinctness of the image. To give an idea of the delicate manipulation required in the construction of a reflecting telescope, we take the case of a speculum of 4 feet aperture and 40 feet focus, as calculated by Sir J. Herschel. If this be first ground to a truly spherical form, it must have a radius of 80 feet, as we have seen above. Now, such a mirror will give a very indistinct image, even under the most favorable circumstances; yet to grind it to the parabolic form, which is practically perfect, leaving the middle untouched, and grinding more and more away from its surface as we proceed outwards to the edges, even at the edges we have to remove a film of metal of only the $\frac{1}{81,818}$d part of an inch, somewhere about the $\frac{1}{100}$th part of the thickness of the paper on which this is printed!

Lenses, whether the object-lens or the eye-lens, have this defect also; but, as a rule, the spherical aberration in lenses is almost negligible compared with *Chromatic Aberration*, which arises from the different refrangibilities (see REFRACTION) of the various colored rays; and leads to the formation, by a lens, of a separate image of a bright object for each colored ray. The remedy consists in *achromatizing* (see ACHROMATIC, REFRACTION) the lens,—i. e., forming it of two or more lenses of different kinds of glass—so that the colors, separated by one, shall be reunited by the others. With a double achromatic lens, in which a convex lens of crown-glass is united to a concave of flint-glass, the focal lengths of the separate lenses can be easily adjusted so as to bring, when in combination, any two assigned rays of the Spectrum (q. v.) simultaneously to a focus; and, by a judicious selection of these two rays, we may reduce the consequences of irrationality of dispersion (see REFRACTION) to a minimum. But this is not all. To construct a lens of a given material which shall have a given focal length, is an *indeterminate* problem; we may assign the curvature of either surface at pleasure, and then that of the other is definite, and can be calculated. Thus, the achromatism of a double-lens can be secured in an infinite variety of ways, and we may impose further conditions; i. e., that the curvatures of the convex and concave surfaces shall be adjusted so as to destroy as far as possible the spherical aberration. Other imperfections, such as those due to DIFFRACTION (q. v.), &c., cannot be here more than alluded to, as they do not admit, within any reasonable limits, of being popularly explained. Nor can we enter upon questions connected with the correction of chromatic and spherical aberrations in eye-pieces, which is effected by the combination of two or more lenses (generally of the *same* material) placed at a certain distance from each other. We may only mention that the defect (for terrestrial purposes) of the common astronomical telescope, the inversion of the image, is overcome by combining two such telescopes, the smaller to examine the image formed by the larger, and therefore to reinvert it. This practically comes to constructing the eye-piece of three lenses at a distance from each other; though, for greater distinctness, four are usually employed.

In the earliest, or Galilean, telescope, the eye-lens is concave; a construction only now used in opera-glasses. It has far less chromatic and spherical aberration than the common astronomical telescope, and is shorter, since the distance between the lenses is the *difference*, not the *sum* of their focal lengths; but it has a very serious defect in the smallness of its field of view. This can only be enlarged, as in opera-glasses, by making the diameter of the object-lens disproportionately great.

Before the discovery of the possibility of forming an achromatic lens, Huyghens, Cassini, and others, had endeavored, by enormously increasing the focal length of the object-glass of the common astronomical telescope in propertion to its diameter, to get rid as far as possible of chromatic aberration. This was called the *aërial* telescope, as the object and eye lenses were mounted separately on stands; the tube (which would have been 100, 200, or even 600 feet long) being dispensed with. Valuable work was done with some of these telescopes) of 125 feet focus, but the longer ones proved unmanageable. The principle involved in these constructions is, practically, the throwing the magnifying power more on the object-lens than on the eye-lens; as the image formed by the former was still so imperfect as not to bear much additional magnification; although achromatic eye-pieces could even then be made with one kind of glass. The great step required for shortening the unwieldly instrument was therefore the perfecting of the object-lens. We have already seen how this was effected. Various very ingenious improvements on achromatic combinations, even yet (we should be inclined to think) worthy the consideration of opticians, were devised by Dr. Blair. He obtained in solutions of mercury or antimony in hydrochloric acid, media, in which, while much more refractive and more dispersive than crown-glass, no irrationality of dispersion as compared with crown-glass could be detected. With these fluid lenses he was enabled to give the telescope an aperture of $\frac{1}{8}$d of its focal length without a trace of residual color.

The *dialytic* telescope, invented in 1828 by Mr. Rodger, and since made by Plössl, seems to promise very well. Its object is to obtain a large aperture for the telescope with a flint-lens (the obtaining of which, in large and perfect discs, is the great difficulty) of moderate size. In this telescope the object-lens is single, and of crown-glass; having, of course, all the defects of the single lens. These are corrected, at some distance in the cone of converging rays, by the interposition of a combination of a pair of much smaller lenses, whose focal lengths are equal for red rays; the first being a convex lens of crown, the second a concave of flint, glass. The adjustments of this instrument for exact correction are, a motion of the pair of lenses to or from the object-lens, to correct chromatic aberration; and a change of the distance between the two smaller lenses, to correct spherical aberration.

Chromatic being so much more serious than spherical aberration, it is not to be wondered at that the idea of substituting an object-mirror, in which the former is absent, for an object-lens, was early suggested. The first practicable scheme for the purpose seems to have been that of Gregory; in which, however, two mirrors are employed. In the skilful hands of Short, this instrument completely superseded the ordinary astronomical telescope. Its chief defects are, the great loss of light by two direct reflections, and the increase of the spherical aberration by the fact that both mirrors are concave. The first defect is incurable, the second was partially overcome by Cassegrain's plan of using a small *convex* mirror for the second reflection. To Newton is due the simple idea of using the combination of a single curved mirror with a plain mirror and an eye-piece; a construction differing only in slight particulars from that now universally adopted for reflecting instruments. Newton constructed several such telescopes with his own hands, some of which are still preserved, as in the apartments of the Royal Society at Burlington House.

The elder Herschel constructed for himself all the instruments, gradually increasing in magnitude and optical power, by means of which he made his grand discoveries; and his son worthily succeeded him, both as constructor and observer.

The gigantic telescopes of Lord Rosse and Mr. Lassell are wonderful examples of delicate art, and have had their full share, with the large achromatics of the present day, in the startling discoveries of modern astronomy.

The process of Liebig for depositing on glass an exceedingly thin film of silver, which, by careful polishing, can be rendered more highly reflective than any other material, has been taken advantage of by Steinheil in the construction of large specula. This is an immense step, since any disc of glass will do, its optical properties not being employed; while, if it be once brought to a true parabolic figure, the silvering may be renewed as often as may be required. One of the great difficulties in the construction and working of large reflectors has hitherto been the casting and annealing of metallic masses of a few tons' weight. This, in the silvered specula, is entirely avoided. We cannot here enter into a description of the processes, often extremely ingenious, which have been devised for the grinding, figuring, and polishing of lenses and specula. The reader who desires strictly scientific information, conveyed in a thoroughly popular form, on this and all other points connected with the subject, is referred to Sir John Herschel's article 'Telescope,' in the *Encyclopædia Britannica*, to which we have been largely indebted, and which has been reprinted in a separate form.

TELFORD, THOMAS, an eminent engineer, was born in the parish of Westerkirk, in Eskdale, Dumfriesshire, 9th August 1757. His father was a shepherd; and during the intervals of his attendance at school, young T. followed the same occupation, diligently employing his leisure moments in the perusal of whatever books were within his reach. At the age of 14, he adopted the trade of a stone-mason; and long years afterwards, when he had attained the summit of his profession, he confessed the advantages which he derived during this period from 'the necessity of making himself acquainted with every detail in the procuring, preparing, and employing of every kind of material, whether it be the produce of the forest, the quarry, or the forge.' In 1780, he removed to Edinburgh; and in 1783, he repaired to London, obtaining employment under Sir William Chambers, who was then engaged on his chief work, the erection of Somerset House. T.'s merits attracted the notice of his employer, and he was appointed in 1784 to superintend the erection of the resident commissioner's house at Portsmouth dockyard, a work which lasted over three years, and afforded T. the opportunity, of which he fully availed himself, of mastering the details of construction of docks, wharf-walls, &c. In 1787 he was appointed surveyor of public works for Shropshire; and his two bridges over the Severn at Montford (3½ miles west-north-west of Shrewsbury) and Buildwas (1½ miles west of Coalbrook Dale), a large number of minor bridges, and other county works, testified to the genius and industry of the rising engineer, and gained for him the planning and superintendence of the projected Ellesmere Canal, 103 miles in length, to connect the navigation of the Severn, Dee, and Mersey—a work which occupied ten years (1795—1805), and greatly added to the already eminent reputation of Telford. In 1790, he was appointed by the British Fishery Society to inspect the harbors at their various stations; and in 1801 he received a commission from government to report on the state of Scotland, and on the desirable public works for that country. As a consequence, the plan of a canal from Inverness to Fort-William was revived, and its planning and construction intrusted to T. (see CALEDONIAN CANAL).

In the same capacity of engineer to the parliamentary commission of roads and bridges for Scotland, he executed more than 1000 miles of road in the Highlands, Lanarkshire, and Dumfriesshire (see ROAD-MAKING), and erected about 1200 bridges, besides churches, manses, harbors, &c. In 1808, and again in 1813, he was invited to Sweden, to report on the projected scheme for connecting Lake Wener with the Baltic, and superintended the construction of the Gotha Canal, by which this was effected, receiving on his departure numerous and valuable marks of the royal approbation. His next great work was the construction of the road from London to Holyhead, including the erection of numerous bridges —among others, of the Menai *Suspension Bridge* (q. v.)—and the last was the execution of the St. Katharine's Docks in London, a work of remarkable merit. His other works are far too many to enumerate. We can only afford to state that, of bridges, the Conway (q. v.), the Broomielaw at Glasgow, the Dean in Edinburgh, the Over at Gloucester (an innovation on the ordinary form); of canals, the Glasgow and Paisley, the Macclesfield, the Birmingham and Liverpool Junction, the Gloucester and Berkeley, the Weaver system, the great tunnel (1¾ miles long) on the Trent and Mersey; of harbors, Peterhead, Banff, Fraserburgh, Fortrose, Cullen, and Kirkwall—were planned by this indefatigable genius, and wholly or partially erected under his superintendence. He was much employed by parliament to report on all public engineering schemes or works of importance, and was also occasionally consulted by the Russian government. For the last few years of his life, he retired from the active duties of his profession, employed himself in collecting and arranging materials for a complete history of his various works, and had the greater portion of the MS. ready when he was seized with a severe bilious attack, and died at Abingdon Street, Westminster, 2d September 1834. His life, entitled *The Life of Thomas Telford, Civil Engineer, written by himself*, was published in 1838, in 1 vol. 4to, accompanied with a companion volume of plates. While a mason in Dumfriesshire, he was known favorably as a writer of short poems, in the homely dialect of his district, which are to be found in the appendix to his autobiography. He completed his imperfect school education during the intervals of business, becoming an excellent linguist, and contributed to the *Edinburgh Encyclopædia*. He was elected a member of the Royal Society of Edinburgh in 1803, and of its more eminent southern sister in 1827.

TELL, a district in the extreme north-west of Africa, stretches along the shores of the Mediterranean, and comprehends the corn-growing tracts extending south from the Mediterranean to the Atlas Mountains, and from west to east through Morocco, Algeria, and Tunis. The T. is noticed under the articles AFRICA and SAHARA (q. v.).

TELL, WILLIAM, was, according to Swiss tradition, a patriot who, in the 14th c., rescued his native district from the tyranny of the House of Austria. His story has been variously told, but that version which has found the widest currency is the following. In the beginning of the 14th c., Albert I. of Austria was striving to annex the three Waldstädte, Uri, Schwyz, and Unterwalden, to his family estates. Hermann Gessler, his bailiff (or *Landvogt*), lived at the castle of Küssnacht, and perpetrated on the people of the district the most atrocious cruelties. A league was formed of the principal men of the Waldstädte to resist the Austrian pretensions, and to it belonged Walter Fürst and William Tell, his son-in-law. Among other acts of tyranny, Gessler placed the ducal hat of Austria on the top of a long pole, erected in the market-place of Altorf, and gave orders that no one should pass without uncovering his head. T. and his little boy one day took no notice of the hat, and were at once dragged before Gessler. He, hearing that T. enjoyed great reputation as a cross-bowman, resolved to make his skill a means of punishing him. He was ordered to shoot an apple from his son's head, and told that if he missed it, he should die. To the amazement of all present, he hit the apple without injuring the child. But this did not satisfy Gessler. Turning to T., he asked him what he meant to have done with a second arrow he had in his girdle. 'To have shot you, if it had slain my son,' was the reply. T. was then seized, bound, and thrown into a boat on the Lake of Lucerne, to be taken with Gessler and his men to the castle of Küssnacht. A sudden Alpine storm sprung up. T. was the only man on board who knew the shore, and could manage a boat in such weather. He was allowed to take the helm, and he soon ran her towards a rocky ledge; he there seized his bow and arrows, sprang on shore, and pushed the vessel back into the water. The storm, however, abated, and Gessler and his party landed. T. lay in wait for them in a rocky defile, and as they passed, he shot Gessler through the heart. This befel in 1307 and was followed by the great Swiss war with Austria—the first of a series which lasted till 1499—in which however, T. took no prominent part. T. was drowned, it is added, in 1350, in attempting to save a friend during a great flood of the river Schächen.

There is evidence that, in 1387, a religious service was instituted to commemorate the act of T. at the place where he lived; and that, in the following year, Tell's Chapel was built on the spot where the boat was said to have landed. Russ and Etterlin, chroniclers who lived towards the end of the 15th c., told his story as true history. Tschudi, who wrote in the first part of the 16th c., repeated it in the form in which it is now familiar to us, and in which it was adopted by Schiller, in his well-known drama. So early as the end of the 16th c., however, doubts were expressed of its authenticity. Guilmann, who wrote a book, *De Rebus Helveticis*, called in question the very existence of Tell. What, he asks, has become of his family and relatives? Why was he not spoken of by his contemporaries? Grasser, the author of a Swiss *Heldenbuch*, pointed out a striking resemblance between T. and Toke, the hero of an old Scandinavian fable, recorded by Saxo Grammaticus. From that period, incredulity became general, and several books were published to show that the story was legendary. One of these, *Guillaume Tell; fable danoise*, was burned by the public hangman at Uri, and then a patriotic feeling was manifested on the subject, which, it is believed, made Swiss writers, including J. von Müller the historian, cautious in expressing farther doubt. Voltaire, in speaking of T., makes the remark, that '*l'histoire de la pomme est bien suspecte*,' and asserts that no

part of the tale had a foundation in fact. His opinion became known all over Europe; and since then, a whole library has been published on the story of T., in Switzerland, Germany, Denmark, and France. The most important works, however, bearing on the question, are (1) Ideler's work, *Die Sage vom Schusse des Tell*, published at Berlin in 1826, in which it is shown that the incident of the apple is purely legendary; (2) an edition of Russ's Chronicle, edited in 1834, by M. Schneller of Lucerne, in which it is proved that serious disparities exist between the different versions of the story as told by the Swiss chroniclers; and (3) a work containing a series of documents relating to eary Swiss history, published in 1835 by M. Kopp, also of Lucerne, in which it is as satisfactorily shown that, although a continuous series of charters exist relative to the bailiffs of Küssnacht in the 14th c., there is no Gessler among them.

T. is nowhere mentioned in contemporary records; but it need not, therefore, be inferred that an obscure peasant did not exist of the name, who shot an Austrian bailiff on the banks of the Lake of Lucerne, who by this act caused a revolt, and who lost his life in attempting to save that of a friend. If such incidents really occurred—and from the early foundation of Tell's Chapel, and other facts connected with it, we must presume they did—it would be easy to explain how they became connected with the old fable of the tyrant, the bowman, and the apple.—Ample information on the Tell controversy will be found in Hisely's *Recherches* (1843); and Vischer's *Die Sage von der Befreiung der Waldstädte* (1867).

TELLEZ, GABRIEL, better known by his literary pseudonym of *Tirso de Molina*, a Spanish dramatist of great reputation, was born at Madrid in 1585, became a monk in 1620, and died in 1648, prior of the order to which he belonged. T. was a friend and pupil of Lope de Vega, whom he almost rivaled in facility of execution. In the preface to his *Cigarrales de Toledo* (1621), a collection of novels and comedies, he reckons the number of the latter composed by him at 300; of which, however, only 68 have come down to us. Besides these, he wrote several Interludes, a great number of *Autos Sacramentales*, an *Acto de Contricion en Verso*, and a *Genealogia de los Condes de Sástago* (Mad. 1640). T. ranks next to Calderon and Lope de Vega as a dramatist. Although he generously affected to consider himself only a follower of the latter, he is really one of the most decisively original geniuses of his country, and imitated Lope in nothing except in cultivating the same national spirit in literature. His plays, deficient in artistic conception, are full of dramatic vitality. The 'situations' are numerous and captivating; the delineation of character fresh, piquant, and vigorous; the wit abundant, and the language richly poetical.—The best edition of T.'s works is that of Don Juan Eugenio Hartzenbusch, in the *Teatro Escogido* (12 vols., Madrid, 1839—1842).

TELLICHE'RRY, a seaport town and military station of British India, in the district of Malabar, 90 miles south-west of Seringapatam. The site of the town is very beautiful, and the neighboring country highly productive, the low lands producing two, and in some cases three, crops of rice in the year. The cocoa-nut tree also grows in great abundance, and is put to many uses by the inhabitants. On account of its salubrity, T. has been called the Montpellier of India. There is a natural breakwater, abreast of the fort, formed by a reef of rocks running parallel to the shore, having a depth within suitable for ships of 500 or 600 tons. Pop. (1871) 20,504.

TELLING FORTUNES is a criminal offence when accompanied with begging of money or with fraudulent objects. Every person going about pretending or professing to tell fortunes, or using any subtle craft, means, or device, by palmistry, or otherwise, to deceive and impose on Her Majesty's subjects, is deemed in law a rogue and vagabond, and may be committed to the house of correction for three months, with hard labor, by a justice of the peace.

TELLI'NIDÆ, a family of lamellibranchiate molluscs; having the mantle widely open in front; the foot tongue-shaped; the siphons separate, long, and slender; the shell usually equivalve and shutting close, the hinge toothed. The species are very numerous, and are found in almost all seas, mostly living in sand or sandy mud, some of them at a considerable depth. The fossil species are also numerous, and are found in the more recent formations. The genus *Donax* belongs to this family.

TELLU'RIUM (symb. *Te*, equiv. 64—new system, 128—spec. grav. 6·183) is a chemical element, which some authorities place among the metals, and others among the non-metallic bodies or metalloids. Although in its outward characters it closely resembles the metals, its close analogies with sulphur and selenium indicate that its true place is amongst the metalloids. It possesses a high metallic lustre, and resembles bismuth in color; it fuses at about 850°, and at a higher temperature is converted into a yellow vapor; it is a bad conductor of heat and electricity. When strongly heated in the air, it burns with a blue flame, and gives off white fumes of tellurous acid. Like sulphur and selenium, it is soluble in cold oil of vitriol, to which it gives a fine purple-red color, and on dilution it is precipitated unchanged; and in these respects differs from all metals. In nitric acid it dissolves with oxidation.

Tellurium forms two compounds with oxygen, viz., *Tellurius acid*, TeO_2, and *Telluric acid*, TeO_3. *Tellurous acid* exhibits very slight acid properties, and in the anhydrous state it combines with acids, and acts the part of a weak base. These salts have a metallic taste, and are said to act powerfully as emetics. The *telluric acid* has only a feeble affinity for bases, but it forms salts, which contain 1, 2, and 4 atoms of the acid to each atom of base. Tellurium unites with hydrogen to form telluretted hydrogen, TeH, which is a gaseous body, analogous to sulphuretted hydrogen, and precipitates most of the metals from their solutions in the form of tellurides, which have a close analogy with the corresponding sulphides.

In experimenting upon the action of the salts of tellurium, it has been found that they possess the power of forming, in the body of a healthy person, compounds which impart to the breath, to the perspiration, and to the gases generated in the intestinal canal, a disgusting fœtor, which makes him a nuisance to every one he approaches; and this smell may last for weeks, although the quantity of tellurium that was administered did not exceed a quarter of a grain.

Tellurium is a rare substance, found chiefly in Transylvania, but recently discovered in Hungary, in North America, and in the Altaï silver mines. It sometimes occurs native, but more commonly as a telluride of gold, lead, or silver. For the method of extracting it, we must refer to any of the larger works on chemistry, and especially to the *Lehrbuch* of Berzelius. It was discovered in 1782 by Müller von Reichenstein, but it was not till 1798 that its properties were accurately studied by Klaproth. The word tellurium is derived from the Latin *tellus*, the earth.

TEMBU (Abatembu, or Tambookie) is the name of an important tribe of Kaffirs, occupying the region east of the present boundary of the Cape Colony, where it forms the eastern limit of the district of Queenstown, formed by Sir Harry Smith in 1849—1850, a rather elevated plateau, from which flow the headwaters of the Kei, Bashee, Tsomo, and other important rivers. They number about 90,000 souls, and are of a less warlike and predatory nature than the adjoining tribes of the Amaxosa and Amagaleka Kaffirs. In the earlier Kaffir wars, and even in the great one of 1835—1836, the Tambookie Kaffirs remained neutral, and even friendly to the colonists; but in the war of 1848—1849, they were induced to join the other tribes, and were defeated with great loss by a small colonial force. In the war of 1851, they were much broken and scattered; but eventually submitting to the British authority, they have quietly located themselves in the unoccupied country east of the White Kei and Tsomo rivers, a good pastoral region, but rather bare of wood. Wesleyan missionaries have several stations amongst the Tambookie tribe, and many of them exhibit very pleasing features. A British resident, paid by the Cape Colony, also resides amongst them.

TEMESVA'R, a Hungarian city, seat of the commander of the Banatish-Servian military frontier, is a strongly fortified place on the Bega Canal, and is about 300 miles south-east of Vienna, with which it is connected by railway. The town is fortified with a triple wall and moat, and has four suburbs. Of the population about a half are German, only a seventh being Magyar, and the rest Rumanians, Jews, and Servians. In T. are a fine cathedral, an ancient castle, a magnificent episcopal residence, an armory, barracks, and a theater. There are manufactures of cloth, silk, paper, and oil, and a brisk transit trade in grain, wax, honey, and brandy, with Transylvania, Servia, and Rumania. T. has endured a vast number of sieges—the latest being that of 1849, when it was bombarded for 107 days by the Hungarian insurgents, but was relieved at the end of that time by Marshal Haynau. Pop. (1869) 32,223; (1880) 33,694.

TE'MPÉ, a narrow valley or gorge, about 4½ miles long, in the north-east of Thessaly, between Olympus (q. v.) and Ossa (q. v.), through which flows the river Peneus. The classic poets (none of whom, curious to say, appear to have ever seen the glen) praise it for its matchless beauty, and hence the name became with them a synonym for any lovely vale. In point of fact, however, the scenery of T. is characterized by wild grandeur rather than by soft sylvan charms.

TE'MPERA, in Painting, the same as *Distemper* (q. v.).

TE'MPERAMENT is a term which has been employed in Physiology ever since the time of Galen, to designate certain physical and mental characteristics presented by different individuals. Dr. Todd, in his article on this subject in the *Cyclopædia of Anatomy and Physiology*, observes that 'the temperaments the existence of which seems most consistent with observation, are those admitted by Cullen, namely, the *sanguineous* and the *melan-*

cholic, the *phlegmatic* being a degree or modification of the sanguineous, and the *choleric* of the melancholic.'

Individuals of the *sanguineous* or *sanguine* temperament are such, according to Cullen, as have the quantity of fluids in the body large in proportion to the solids; the habit of body soft and plump; the skin smooth, white, and readily sweating on exercise; the hair soft, and generally pale, passing from thence to a red tint; the complexion ruddy; the eyes blue; the bodily strength moderate; and the mind sensible, irritable, cheerful, and unsteady. In persons of the *melancholic* temperament, the habit of the body is somewhat hard and meagre; the skin and complexion coarse, and of a dun color; the hair hard, curly, and black; the strength considerable; the mind slow, disposed to gravity, caution, and timidity, but tenacious and steady.

Some writers recognize a *nervous* temperament, in which the predominating characteristic is a great excitability of the nervous system, and an undue predominance of the emotional impulses. This temperament is always associated with the sanguineous or the melancholic. In both sexes, the characteristics of the temperaments are far less manifest in old age than in earlier life. If it be admitted, as Dr. Todd believes, that a constant connection exists between color and temperament, it obviously follows that the nature of the temperament is determined by certain peculiarities in the physical condition of the organism. The different temperaments often merge so gradually into one another that it is in many cases difficult to decide positively to which variety any special case belongs.

TEMPERAMENT, in Music, a system of compromise in keyed instruments for the avoidance of the necessity presupposed by the strict relation of musical intervals of having a separate row of keys corresponding to each tonic. Taking C as keynote, the ratios of the notes of the diatonic scale, as derived from the number of vibrations in a given time of a string sounding that note (see MUSIC) are :

C	D	E	F	G	A	B	C
24	27	30	32	36	40	45	48

The intervals between these notes are by no means equal, and may be thus expressed in numbers by logarithms :

C	D	E	F	G	A	B	C
	51	46	28	51	46	51	28

We have here three species of intervals, of which those represented by 51 are called major tones; those by 46, minor tones; and the smaller intervals represented by 28, semitones. These intervals will evidently only serve with C as keynote. If, for example, we start from D instead of C, we find E a tolerable, though not quite correct, second to D; but the third and seventh of the scale are entirely wrong.

Were the major and minor tones equal, and each semitone exactly half a tone, the insertion of a note in the middle of each tone dividing the seven intervals would make it immaterial where the scale began; any one of the twelve notes becoming alike available as a keynote; and though such equality is contrary to the immutable principles of harmony, an arrangement based on it is found practically to give but little offence to the ear. In what is called the *equal temperament*, the twelve intervals are all of the same length, and no advantage is given to one key over the rest. This is, in theory at least, the temperament adopted in the pianoforte. Another system, known in this country as *Smith's* or the *vulgar temperament*, in which some keys were favored at the expense of others, has been much used in organs. While the keys of B♭, F, C, G, D, and A are more perfect than on equally tempered instruments, E♭, A♭, D♭, and F♯ contain some very harsh intervals. The bad fifths and thirds which exist in these keys are designated by musicians by the name of *Wolf* intervals. This mode of tuning the organ is being more and more abandoned for the equal temperament, or an approximation to it. The different characters of the various keys often observed on the pianoforte, as well as the organ, could have no existence were the temperament absolutely equal, and arise out of the circumstance that this strict equality is not altogether adhered to in practice.

TE'MPERANCE. *History of the Movement.*—The origin of the temperance movement dates from the beginning of the present century; and the merit of having taken the first steps in the matter belongs to America, where the vice of drunkenness appears to have reached an alarming height about that time. In the month of April 1808, a society was established at Moreau, county of Saratoga, in the state of New York, consisting of 43 members; one of whose rules was as follows : 'Art. 4. No member shall drink rum, gin, whisky, wine, or any distilled spirits, or compositions of the same, or any of them, except by the advice of a physician, or in case of actual disease (*also excepting at public dinners*), under the penalty of 25 cents, provided that this article shall not infringe on any religious rite.'

This society had other rules prohibiting members (under penalties) from offering any of the above liquors, or from being intoxicated; but though it continued to exist for 14 years, it does not seem to have accomplished much good. Gradually, however, the attention of the clergy and of philanthropical laymen was called to the subject; and after a series of sermons had been preached and published against a vice whose rapid progress was threatening (according to Dr. B. J. Clarke) to make the Americans 'a community of drunkards,' a society was started at Boston (February 1826), called *The American Temperance Society*, 'to restrain and prevent the intemperate use of intoxicating liquors.' In 1829, *The New York State Temperance Society* was formed; and before the close of the year, 1000 local societies, with 100,000 members, were in existence, and a periodical, entitled *The Journal of Humanity*, established to promote the new movement. Rumors of the progress of temperance societies soon reached the Old World, and in August 1829, a society was started at New Ross, in the county of Wexford, Ireland, under the auspices of the Rev. George Whitmore Carr, the members of which pledged themselves 'to abstain from the use of distilled spirits, except as a medicine in the case of bodily ailment;' and further, 'neither to allow the use of them in their families, nor to provide them for the entertainment of friends.' Simultaneously, a movement in favor of temperance was begun in Belfast and the north of Ireland, by the Rev. Dr. Edgar, Rev. Dr. Cooke, and Rev. Mr. Morgan, and before 12 months were over, 60 societies had been constituted, numbering about 3500 members, both Catholics and Protestants. Meanwhile, Scotland had not been uninfluenced. As early as October 1829, Mr. John Dunlop of Greenock, a justice of peace for Renfrewshire, after lecturing on the subject of temperance in Glasgow, Stirling, and elsewhere, succeeded in forming a society at Greenock, the first in Scotland, and the precursor of *The Glasgow and West of Scotland Temperance Society*, formed in the ensuing November. Mr. Dunlop is thus entitled to be considered 'the Father of temperance societies in Great Britain.' In his early labors, he was greatly assisted by Mr. William Collins of Glasgow, who became the editor and publisher of the *Temperance Record* (1830—1835).

The rules of *The Glasgow and West of Scotland Temperance Society* were substantially the same as those of the American and Irish societies—the members voluntarily agreeing 'to relinquish entirely the use of ardent spirits, except for medicinal purposes,' although 'the moderate use of other liquors is not excluded.' The zeal and activity of this society were remarkable. According to the Report read at the first annual meeting (December 30, 1830), it had circulated in the course of the year 425,300 tracts and 20,200 pamphlets, and numbered in Glasglow alone 5072 adherents; while it was stated that throughout Scotland at large there were 130 societies, and 25,478 members. It is not necessary to follow further in detail the course of the temperance movement, *strictly so called*, in Scotland, except to remark, that members of the clergy now began to interest themselves in it, and at the close of 1831 there were 187 ministers of various denominations in Scotland connected with the cause; but we must now notice the introduction of a new and more stringent application of the temperance principle. On the 21st September 1830, Mr. John Davie, and several other members of the Temperance Society of Dunfermline, pledged themselves to 'total abstinence from all intoxicating liquors—small-beer excepted, and wine on sacramental occasions;' and in the course of the next two years, 'Total Abstinence Societies' were started in Glasgow, Paisley, and other places. In 1830, the temperance movement extended to England. Mr. Henry Forbes, a merchant of Bradford in Yorkshire, happening to be in Glasgow on business, had attended one of the meetings of the Glasgow Society, became deeply interested, and on his return home took steps to organize a Bradford Society (February 2, 1830). Another society was formed at Warrington (April 4, 1830); a third at Manchester (May 12, 1830); and by the close of the year, about 30 temperance societies were in existence, numbering in all 10,000 members.

In June 1831, *The British and Foreign Temperance Society* was organized in London, mainly through the persevering efforts of Mr. William Collins of Glasgow. This was for many years the leading society of the party, its patron being the Bishop of London, and its vice-presidents including several other prelates, distinguished officials both civil and military, and a few members of parliament. The pledge taken by its members was simple : 'We agree to abstain from distilled spirits, except for medicinal purposes, and to discountenance the causes and practice of intemperance.' We have not space to narrate its history and progress in detail, but we may notice that it was instrumental in awakening an interest in the temperance movement both in the army and navy, and that, in the course of a single year (1831—1832), it could boast of having induced 400 old Greenwich pensioners to give up their grog!

Gradually, however, the more fervid friends of temperance in England arrived at the same conclusion as the Dunfermline 'reformers' viz., that a crusade against gin and other 'alcoholic'

liquors was not enough; that 'beer' was the great cause of drunkenness in their country, and that nothing but total abstinence from all intoxicating drinks would cure the evil. The movement in this direction first took shape at Preston in Lancashire, in September 1832, when Mr. Joseph Livesey, and some other members of the Temperance Society there, pledged themselves 'to abstain from all liquors of an intoxicating quality, whether ale, porter, wine, or ardent spirits, except as medicines.' An active propagandism in all the principal towns of Lancashire followed, and a considerable number of adherents were gained to the new cause. In September 1833, according to the commonly received story (see Burne's *Teetotaller's Companion*, p. 333), the notable word *Teetotal* was first used. A certain Richard Turner, or, as he was more generally called, 'Dicky Turner,' a plasterer's laborer or *lime-larry*, who was much given to holding forth in the Lancashire dialect at the meetings of the new sect, happened in the course of a philippic against temperance to say: 'I'll hev nowt to do wi' this moderation—*botheration*—pledge; I'll be reet down tee-tee-total for ever and ever.' 'Well done, Dicky!' said Mr. Livesey: 'that shall be the name of our new pledge.'

This origin of the word, which appears to make it but a stuttering pronunciation of *total*, has, however, been disputed; and it is affirmed that the term is simply a Lancashire phrase for final, thorough, or complete; thus, when a man is discharged merely for want of work, he is said to be *sacked*, but when discharged from inability to work, *teetotally sacked*. Whatever may have been the origin of the term, the new sect was resolved to be 'thorough.' In April 1834, a *Youths' Temperance Society*, on strictly teetotal principles, was formed at Preston, and before a year had passed, it reckoned nearly 1000 members. By dint of zeal, respectable teetotal societies were also established at Manchester (August 1834), Lancaster (November 1834), Colne (December 1834), Isle of Man (December 1835), and numerous other places. Meanwhile (September 1835), a conference of Lancashire and Yorkshire delegates was held at Manchester, and a new general society formed under the title of *The British Association for the Promotion of Temperance on the Principle of Total Abstinence from all Intoxicating Liquors*. This title clearly indicated the ambitious views of the new sect. It wished, and it hoped ere long, to speak in the name of the whole temperance party; and as early as 1836, one of the Yorkshire district societies, that of Wilsden, ventured to memorialize *The British and Foreign Temperance Society* of London on the subject of the total abstinence pledge. The answer that it received showed that a disruption was not far off. In Scotland and Ireland, the progress of teetotalism, as distinct from temperance, was not at first very marked; but its votaries were resolute, and held vehement discussions, public and private, with the advocates of the rival system, in which they were generally considered victorious by the crowds before whom they disputed. During 1834—1835, teetotalism was struggling hard for recognition in London—the influential leaders of the old Temperance Society being dead against it. At length, however, owing to the persevering efforts of Mr. Livesey of Preston and other enthusiasts, the teetotallers got a footing, and, in September 1835, established *The British Teetotal Temperance Society*, which, in August 1836, was merged into *The New British and Foreign Society for the Suppression of Intemperance*. Teetotalism now in turn began to get the upper hand, and in the course of the next two or three years, the 'moderate' party almost disappeared; the majority of its members doubtless passing over to the ranks of the total abstainers. But these now fell out among themselves.

Up to 1839, *The New British and Foreign Society* had two pledges, the long and the short; the former including the 'neither give nor offer' clause; and the latter omiting it. The more rigorous teetotallers made strenuous efforts to get the 'short' pledge abolished, which were as strenuously opposed, and in a very brief period the whole teetotal world was up in wild commotion on the subject. Various meetings of 'delegates' from the different societies in England, Scotland, and Ireland were held in London in May 1839, under the presidency of Earl Stanhope, and scenes of the utmost disorder ensued. The result was a temporary disruption, and the formation of two societies. Still the cause prospered in spite of fierce distractions. Strong provincial associations were formed in Yorkshire, Leicestershire, Lancashire, Norfolk, and Cornwall and Wales, almost always on the 'long pledge' principle. In Scotland, the 'long pledge' took deep root; indeed, after 1837—1838, the 'short pledge' was scarcely ever thought of. But it was in Ireland that the most brilliant successes attended the movement. In 1838, Father Mathew (q. v.) commenced his extraordinary career, and in less than two years, 1,800,000 men and women were enrolled in *Ireland's Great National Total Abstinence Society*.

The subsequent history of the movement must be briefly sketched. In November 1842, the disruption, above mentioned, of *The British and Foreign Temperance Society* was healed, and the two societies which that disruption had called into existence were amalgamated in *The National Temperance Society*. The work of proselytizing then went on vigorously. Innumerable tracts were circulated, and all Britain echoed with the noise of infinite speech. Excursions, processions, Exeter Hall demonstrations, incessant tea-parties, &c. were got up with enthusiasm, which speaks volumes for the energy and sincerity of the teetotal agents. But in a less showy though more noble way, the missionaries of the new faith pursued their benevolent work in the lanes and alleys of large cities, the haunts of profligacy and dissipation, where they sought out the homes of drunkards, and tried (not without success) to rescue them from the power of the horrible vice that was dragging them to destruction. Action of this sort—whatever one may think of the movement as a whole—is to be spoken of only with reverence. In August 1846, *The World's Temperance Convention* met in London, on which occasion 302 delegates were present, representing different societies in the United Kingdom and the United States. Since then, the temperance cause has steadily, if not rapidly, progressed. It has recently been estimated that there are not fewer than 4,000,000 total abstainers (inclusive of juveniles) in Great Britain and Ireland, and a much greater number in the United States of America. Of late years, total abstainers have devoted themselves mainly or largely to advocating the necessity or propriety of imperial legislation on the subject of intoxicating liquor.

A very extensive development of the temperance movement is that known as *Good Templarism*. It originated in New York in 1851, and rapidly spread through the United States. In 1868, the order established itself in England, in 1869 in Scotland, and in 1870 in Ireland. Its progress has been singularly rapid. In England alone, exclusive of Scotland, Ireland, and Wales, there were in 1875 no fewer than 3570 'lodges,' having 168,425 members, estimated in 1880 to have increased to more than 200,000 persons. These of course do not represent absolutely new adherents to the temperance cause. They are in many cases members drawn from the older temperance societies, though it is also an undoubted fact that the order has been very successful in making fresh converts to the cause of total abstinence. The name is derived from the famous *Knights Templars*, and originated in a fanciful analogy between the functions of the ancient order of military monks, and the modern disciples of temperance. As the former were enrolled to defend the Holy Sepulchre and the interests of religion, so the latter are banded together to protect Christianity against a worse foe than the Saracens, viz., 'the drinking institutions of the land.' It is professedly a *religious* movement, and its ritual is evangelical. Its platform is absolute prohibition of the manufacture, importation, sale, or use of all intoxicating liquors as beverages; but it owes its great popularity to certain peculiarities in its constitution, its picturesque or showy ceremonial, and its aim to combine social and festive amusements with missionary zeal. —See *Good Templarism*, by the Rev. George Gladstone (Glasgow, 1872); as also the several magazines of the order. A more recent abstinence movement is the *Blue Ribbon Army*, which counts its supporters by thousands. The *Salvation Army* is also a temperance organization, in so far as those joining it must be abstainers.

Pleas and Counter-pleas.—The question of abstinence from intoxicating liquors is capable of being argued on three distinct grounds, *scriptural*, *physiological*, and *social*.

The Scriptural argument in favor of abstinence from intoxicating liquor may be briefly stated. The only 'strong drink' mentioned in the Bible is wine. It is both praised and blamed. The question raised by teetotallers is: Are the sacred writers referring in both cases to the same kind of wine? This they deny, and endeavor to make good their denial, by an appeal to the original Hebrew. On examination, it is found that ten or twelve different designations for wine are used, but the two by far the most frequent are *yayin* and *tîrôsh*. The first of these is the generic term for wine, and therefore (say the advocates of total abstinence), as it *must* embrace fermented liquor, it is the word used when wine is denounced. Thus, it is *yayin* that is 'a mocker' (Prov. xx. 1), that is not to be looked upon (Prov. xxiii. 31, 32), &c. On the other hand, when wine is praised, *tîrôsh* is the word used, and *tîrôsh* (it is asserted) means the wine in clusters, that is, the actual grape itself, or the unfermented juice thereof, then, as now, liberally drunk as a beverage by the inhabitants of Syria and elsewhere. The application of this view to the New Testament is obvious. If there was a wine that might be used, as well as a wine that was condemned—which, ask the teetotallers, would Christ and his apostles be most likely to sanction? The wine that 'maketh red the eyes,' that 'biteth like a serpent, and stingeth like an adder,' that 'deceiveth,' that 'maketh drunken' and 'mad;' or the wine that 'maketh glad the heart,' that is 'good,' a 'blessing,' &c.;—in a word, *yayin* in any of its dangerous forms (*sôbe*, from the root to 'soak;' *chemer*, the 'foaming or bubbling:' and *mesec*, *mezeg*, *mimsac*, the mixed wines), or the innocent *tîrôsh*, that cheers, but not inebriates? It is conceived that there can be but one answer to this question, and that every candid and reverent Christian must be forced to the conclusion, that the wine which Jesus made at the marriage-feast at Cana of

Galilee, and used in his last supper with his disciples, and which Paul advised Timothy to drink for his stomach's sake, was the unfermented, innocuous, and popular *tîrôsh*.

To this it is replied that the distinction made between *yayin* and *tîrôsh* does not exist. Both parties are agreed that the former term is the generic one (corresponding with the Greek *oinos*, the Latin *vinum*, and the English *wine*, with all of which it is believed to be etymologically connected); but it is denied by the scriptural opponents of total abstinence that *yayin* means fermented, and *tîrôsh*, unfermented wines, exclusively. Not to trench upon the chemistry of the question, which, it is affirmed, wholly disproves the possibility of the 'juice of the grape' being kept for any length of time without undergoing a process of fermentation, and thereby acquiring to a certain degree intoxicating properties, it is alleged that the etymology of *tîrôsh* does not favor the teetotal view. According to Gesenius, it is derived from the root *yârash*, 'to get possession of;' that is, of the brain. Dr. Lees, indeed, quotes Bythner as suggesting that it may have been so named because the vine was a 'possession' in the eyes of the Hebrews; but this is extremely improbable, and in the absence of other explanations, that of Gesenius is certainly to be preferred. Again, *tîrôsh* is not exclusively used to denote the 'fruit' (strictly so called) of the vine; the dreaded *yayin* performs the same harmless function—e. g., in Jer. xl. 10, 12, where it is connected with a verb significant of 'gathering,' and in Ps. civ. 14, 15, with another expressive of growth. It is even denied that *tîrôsh* is ordinarily to be so understood, for although, being mostly found in connection with 'corn,' the verb applied to the consumption of that article of food is by *zeugma* made to apply to the 'wine' also, yet in the only passage where the act of consuming *tîrôsh* alone is mentioned (Is. lxii. 8, 9), the verb is *shâthâh*, which invariably signifies the act of drinking. Lastly, it cannot be shown that *tîrôsh*, when it does mean wine, means innocuous wine. No doubt, *yayin* is the one generally employed when wine is denounced, and *tîrôsh* when it is praised, but this is not uniformly the case, for in Hos. iv. 11, 'whoredom and wine (*yayin*) and new wine (*tîrôsh*) take away the heart,' *tîrôsh* actually forms (as has been remarked) 'the climax' of intoxicating influences. The conclusion, therefore, to be drawn from a consideration of Scripture is, that the distinction insisted on by total abstainers between the two terms —viz., that the one (*yayin*) means fermented, and the other (*tîrôsh*) unfermented wines, is one that cannot be maintained. Both must be held as referring to fermented intoxicating wine; and the praise of *tîrôsh* is simply to be considered a recommendation of the moderate use of ordinary wine, as the condemnation of *yayin* is to be regarded as a solemn prohibition of excess in the same.

The physiological argument in favor of total abstinence necessarily takes various shapes; for it is concerned with physiological questions which are yet, to a great extent, matter of opinion—of speculation and conjecture, not of science. A question arises upon three distinct points: 1st, the effects of alcoholic liquors in quantities sufficient to produce intoxication; 2d, their effects when habitually used in moderate quantities; 3d, the effect of abstaining from them altogether.

Upon the first point, teetotalers usually maintain that insanity, idiocy, almost every form of organic disease, many chronic, not a few acute disorders, are frequent results of habitual intoxication; that the children of drunkards are often idiotic, and have transmitted to them various diseases, which are produced by excessive drinking—which, therefore, tends to the deterioration of the race; that drunkards are always the first victims of epidemics; and that it can be shown from tables of mortality that drinking has a marked effect in shortening life. It is not disputed that many of these effects can be connected with the habitual use of liquors in excess; but as to some of the most striking of them, it is denied that they are physiological effects of such excess—being not direct results of hard drinking, but due to the bad conditions under which poor people who drink hard usually live. The question between teetotalers and those who differ from them, at this point, however, is only a matter of degree. The latter admit that alcohol, in narcotic or intoxicating quantities, produces only injurious results. In such quantities, it has a deteriorating, a devitalizing influence upon the brain and nervous tissue, and habitual excess in its use is attended by a progressive impairment of nervous structure, indicated at length by such results as epilepsy or delirium. See INTOXICATION. But the results of excess differ greatly, it is said, in the case of different persons, so that, not unfrequently, many years of hard drinking do not affect the system of the drinker in a marked degree.

It is upon the second point—the habitual use of alcoholic drinks in moderation—that the opinion of teetotallers serious conflicts with that of many physiologists. The teetotal argument—leaving out minor points such as an alleged effect of alcohol in impairing the digestion—may be stated thus: 1. Alcohol can never have been intended by nature for the food of men. It is never produced spontaneously in nature. The vegetable world yields in abundance the principles which form the flesh, and those which keep up the heat of the body, but the healthy plant never produces alcohol. In the body, too, in health, food is never converted into alcohol. And the body does not merely not produce alcohol; it treats it as a foreign element, and gets rid of it as fast as possible. 2. Alcohol in the body, by taking up the oxygen supplied through the lungs, checks the burning of tissue, upon which life and the production of energy, muscular or mental, depend; and similarly it impedes the efforts of the body to get rid of the waste matters which are the products of the burning. It thus lowers vitality, vitiates the blood, and prevents the production of healthy fibre. Toddy or beer taken at bedtime, instead of being favorable to health, has just the same effect, according to Dr. Carpenter, with sleeping in a four post bed with the curtains carefully tucked under the bed-clothes. In either case, that is, there is a diminution of the supply of oxygen required for vital processes, especially for burning the waste of the body. 3. The stimulation produced by alcohol is succeeded by a recoil or reaction; and to produce a certain effect of stimulation, the quantity taken must constantly be increased. From this cause—to say nothing of social influences connected with drinking calculated to produce the same result—moderate drinking tends to pass into excessive drinking, about the evil consequences of which there is no dispute.

The physiological opinion opposed to those arguments is, that while alcohol, like other similar substances, has, in large quantities, a narcotic, a devitalizing effect, it has in small quantities a stimulating effect, between which and narcotism there is a difference, not of degree, but of kind. The stimulating effect is precisely the same with that of highly-nutritious and easily digested food; as regards the vital functions, it differs from the effect of ordinary food only in rapidity of production. It does not substitute an abnormal for the normal action of the bodily organs; it restores their natural functions; and it is capable of rectifying either deficient or redundant functional action. The only positive difference of effect between ordinary food and alcoholic stimulation is, that the latter does not, to any great extent, add to the bulk of the body. Their is no recoil or reaction after it, except that, as in the case of ordinary food, the effect is exhausted after a time. There is nothing to support the belief in a reaction, except the depression involved in the gradual recovery from the narcotic effect of a large quantity of alcohol; but between the narcotic effect of a large, and the stimulating effect of a small, quantity, there is, as already said, a difference of kind—their connection is merely accidental. And the experience of mankind—the fact that moderate drinking does not usually pass into excessive drinking—sufficiently shows that it is not found necessary to increase the quantity used for stimulation. Since stimulation restores the natural functions, it, of course, is capable of removing the consequences of functions being perverted. Thus, it is maintained that, among other things, it gives relief from pain and muscular spasms, reduces the circulation when too rapid, produces healthy sleep, and removes general debility, as well as the fatigue of special organs. Whether it, to an important extent, affects the waste of tissue, or keeps waste matters in the blood, is at present undetermined; however this may be, there is no justification for holding that life is to be measured by the aggregation of tissue, or the rapidity of bodily changes. The notion that alcohol checks the burning of tissue by taking up the oxygen received by the lungs originated when it was believed, upon the authority of Liebig (it was so believed until a few years ago, but the contrary is generally held now), that alcohol was altogether decomposed in the body. If these views are correct, it follows that alcohol taken cautiously and in small quantities—the quantities varying with the circumstances and with the constitution of the individual—may be used not only with safety but with advantage.

Under the third head, teetotallers, of course, maintain that total abstinence is highly favorable to health. They adduce their personal experience; the mortality statistics of one or two regiments and of ships' crews mainly, or entirely, made up of abstainers; the evidence of arctic voyagers on the one hand, and of travelers in tropical regions on the other, to prove that in every climate health can be maintained, and is most likely to be maintained, when no use is made of alcoholic drinks. On the other side, the fact that men of all races use alcoholic beverages, is held to show that men, living as men must usually do, find those beverages useful, if not necessary. It is not disputed that many persons live in health without them—that persons having an abundance of wholesome food, not overworked, living in well-constructed houses, and in wholesome air, can usually dispense with them. But when some, or all, of those conditions are wanting—which in towns, at any rate, happens in all but exceptional cases—it is alleged that a nearer approach to health is made when a moderate use is made of alcohol.

The social arguments in favor of total abstinence, though very weighty and earnestly insisted upon, can be indicated in a few sentences. It is affirmed that the use of alcoholic drinks is at the

root of all the misfortunes of the poorest and most numerous class; that it is the chief cause of pauperism, the chief cause of crime, a frequent occasion of immorality; that it lowers the health and shortens the life of the great mass of artisans and laborers, makes their homes wretched, and exposes them and their families to the evils and temptations of chronic destitution. Then, such are the seductive influences of drink and good-fellowship, that moderate drinkers are in danger of becoming drunkards; thus the use of liquors effects the ruin of a considerable percentage of the middle and upper classes.

Total abstinence is demanded as a measure of personal precaution, because no one who drinks at all is safe against falling into drunkenness; as a patriotic duty, incumbent upon those who desire the improvement of the poorer classes; as a duty of example which every man owes to his neighbor, and which, involving self-denial, must have a favorable reflex influence upon character. On the other side, it is not denied that drinking is closely connected with, or that it exasperates, the misery undergone by the poor; but it is denied that it is the cause of the misery. It is maintained that drinking must be regarded as an effect of the bad conditions inherited by the poor, and under which they live. Persons born in close alleys, and brought up in foul air, living always from hand to mouth, often upon insufficient or unwholesome food, feel (it is said) a need of stimulants to support vitality. It is affirmed that the fluctuations of crime (properly so called) do not depend upon the amount of drinking, but—so far as they can be traced to one circumstance—upon variations in wages; that it is destitution, not drunkenness, that contributes most largely to the production of crime. The drunkenness, the crime, the pauperism, it is maintained, cannot be permanently reduced except through a material and moral improvement being effected among the poor. Then it is denied that moderate drinkers, in general, are in any danger of becoming drunkards; it is persons wanting in prudence, and of intemperate constitution, who are exposed to that danger.

Of late years, total abstainers—in unison with others who, though not themselves abstainers, are anxious to promote public sobriety—have exerted themselves to obtain, in one shape or another, a legislative prohibition of the trade in drink. This movement was set on foot in Great Britain in 1853, by an organization called 'The United Kingdom Alliance,' on account of the success which had crowned the exertions of teetotalers in Maine and many other of the United States of America. In Maine, the liquor-traffic was suppressed in 1846; the law was made more stringent by a provision for confiscating all alcoholic drinks in 1851; and though, in 1856, the existing laws were repealed, and it became lawful to distil spirits, to sell spirits, and to have spirits in possession, drinking-houses continued to be prohibited. (Kansas had in 1881 the strictest prohibitory liquor-law.) The 'Alliance' finding it impossible to carry a Maine liquor-law here, first asked for a Permissive Bill, enabling the ratepayers of a parish, if a majority of two-thirds of them should think fit, to suppress all public-houses within the parish. Subsequently, they have demanded LOCAL OPTION (q. v.). They support this claim by a variety of arguments. Alcohol, they say, being a poison, its sale ought to be subject to the same restrictions as that of other poisons. The legislature has admitted the exceptional and dangerous nature of the liquor-trade, by putting it under strict regulation; in consistency, it should suppress it as a trade altogether. They allege that the amount of drinking in a place always varies directly with the number of public-houses; and then that the amount of crime and of pauperism varies directly with the amount of drinking.

In 1857, Dr. Lees calculated the expense of the use of liquors to this country at 120 millions a year—the cost of the liquor being put at 60 millions, and the remainder of the amount made up by allowing for the crime and pauperism caused by drinking, the loss of time in drinking, and, through disease induced by drinking, the waste of life consequent upon it and many minor items. This money, it is said, if not spent upon drink, would have a marvelous effect in improving the condition of the poor. On the other side, it is maintained, *in limine*, that the subject matter of this bill is so important, and so full of difficulty, that parliament should not delegate its functions in respect of it to the ratepayers; also, that to do so would be to plant, in every parish in the country, the seeds of perpetual strife. Upon the merits, it is said that a prohibitory law could not be carried out—at any rate in large towns, where the worst evils connected with drinking are found; and that systematic attempts at evasion would be made, which would demoralize the people, and put them in chronic antagonism to the law. Besides the arguments already stated upon this side, it is urged that—excepting the case of poisonous substances—it is no part of the duty of a governing body to say to its people: You shall not spend your money upon this or that; that it is unreasonable, in a fiscal point of view, to speak of the national resources being wasted upon liquors, any more than upon tea or beef, or other substances which perish with the using; and that the power of procuring articles which are desired is what men work for—the great motive of industry. It is also maintained that compulsory abstinence from drink would not produce the same results as voluntary abstinence; that men would seek indemnifications, resorting, it might be, to other and more injurious narcotics than alcohol, and to vices which might be even more injurious than drinking. It is said that abstinence, to be valuable, must be a sign of a moral improvement; and that it is safest we should leave the poor to face the temptations of their situation, trying to fortify them against these temptations by education, by giving them just moral and religious views—at the same time, holding before them the spectacle of temperance and its results in the case of the more comfortable classes.

The following are the leading organizations in Great Britain, that, with various modifications of creed, carry on the temperance agitation. They can claim as directors and advocates men of acknowleged position and ability; and the aggregate sum of money spent annually is very great. The National Temperance League, London (organ, the *Weekly Record*); the United Kingdom Alliance, Manchester, with numerous branches (organ, the *Alliance News*); the Church of England and Ireland Temperance Society, London (organ, the *Church of England Temperance Magazine*); the Scottish Temperance League, Glasgow (organ, the *League Journal*); the National Band of Hope Union, London (organ, *Band of Hope Review*). The Roman Catholic and Methodist branches of the Temperance Society form distinct organizations. The *Good Templars* have been named above.

TEMPERATURE. See TERRESTRIAL TEMPERATURE.

TE'MPERATURE OF THE BODY. It is admitted, as a result of the observations of numerous physiologists, amongst whom our countryman, Dr. John Davy, stands pre-eminent, that although the range of temperature varies in different parts of the human body, the normal temperature at completely sheltered parts of the surface amounts to 98°·4, or a few tenths more or less in temperate climates; and that if there is a persistent elevation above 99°·5, or a depression below 97°·3, some form of disease is certainly indicated. (In warm-blooded animals, generally, the temperature is one degree lower at completely sheltered parts of the surface than in the back of the mouth, or other accessible internal parts.)

Some of the circumstances which cause a deviation from the normal temperature are mentioned in the article on ANIMAL HEAT. It may be further noticed, that exposure to cold without exercise, and sustained mental exertion, reduce the temperature, and that the amount of heat is at first reduced after a full meal, although, as stated in the above-named article, it subsequently rises. Moreover, in the tropics, the average temperature is nearly 1° higher than in temperate regions.

When the temperature rises in cases of disease, the following relation to its augmentation and that of the pulse has been established: *an increase of temperature of* 1° *above* 98° *corresponds with an increase of ten beats of the pulse in the minute.* Thus, if the pulse is 60 at 98°, it is 70 at 99°, 80 at 100°, and so on. It is now established beyond all doubt, by the observations of Wunderlich, Virchow, and many other foreign physicians, and by Parkes, Jenner, Aitken, and Ringer in this country, that the preternatural heat which in certain cases can be detected by the themometer, and may exist to the extent of 4°, 6°, or even 8° above the healthy average, and which varies in amount in different diseases, in different persons, and at different times of the same day, is the essential symptom of fever. Dr. Davy in his *Physiological and Anatomical Researches*, vol. i. p. 206, describes the case of a lunatic soldier, in whom the accidental discovery that his temperature was 6° above the normal standard, led to the detection of tubercular disease of the lungs and intestines. Wunderlich, whose experience embraces at least half-a-million exact thermometric observations, bears unqualified testimony to the value of this mode of investigation in the early detection of disease, and as often furnishing an important guide to treatment. Some of these instances are quoted by Dr. Aitken in his *Science and Practice of Medicine*, 3 ed. vol. i. pp. 44—46.

We give in a condensed form a few of the more important of these observations. In *ague*, the temperature of the body begins to rise several hours before the beginning of the paroxysm; and after the disease *seems* to have disappeared, a periodic increase of the temperature may still be detected, and as long as this continues, the patient is not really cured. In *typhoid fever*, the rise of temperature, or its abnormal fall, will indicate what is about to happen three or even four days before any change in the pulse or other sign of mischief has been observed. A sudden fall of temperature has thus denoted intestinal hæmorrhage several days before it appeared in the stools. A fall as low as 93° was noticed by Parkes in a case of this kind. When a person, who yesterday was healthy, exhibits this morning a temperature above 104°, it is almost certain that an attack of ephemeral fever or ague is coming

on, and should the temperature rise up to or beyond 106°·3, the case will certainly turn out one of ague or of some other form of malarious fever. If during the first day of illness, the temperature rises to 106°, it is certain that the patient does not suffer from typhus or typhoid fever; and if the temperature of a patient, who exhibits the general signs of pneumonia, never reaches 101°·7, it is certain that there is no soft infiltration in the lungs. 'In typhoid fever, a temperature which does not exceed on any evening 103°·5, indicates a probably mild course of fever. A temperature of 105° in the evening, or 104° in the morning, shows that the attack is a severe one, and forebodes danger during the third week. On the other hand, a temperature of 101°·7, and below, in the morning, indicates a very mild attack, or the commencement of convalescence. In pneumonia, a temperature of 104° and upwards indicates a severe attack.

'In acute rheumatism, a temperature of 104° is always an alarming symptom. In a case of jaundice otherwise mild, an increase of temperature indicates a pernicious turn. In tuberculosis, an increase of temperature shows that the disease is advancing and that untoward complications are setting in. In short, a fever temperature of 104° to 105° in any disease indicates that its progress is not checked, and that complications may still occur.' —*Op. cit.*, p. 21. We may further observe that, from the observations of Dr. Sidney Ringer, a persistent elevation of temperature exists as an invariable precursor of the growth of tubercle in any organ. As a general rule, when the temperature rises continuously to 106°·2, the prognosis is unfavorable; and when it rises to 110°, a fatal issue is almost certain. The diseases in which the highest temperatures have been observed are scarlatina, in which it has been noted at 112°, and tetanus, in which, at the period of death, it was 112°·5, and an hour afterwards was 113°·8. In Dr. Aitken's work, the reader will find a series of diagrams illustrating the range of temperature in ague, erysipelas, measles, pneumonia, simple continued fever, scarlatina, small-pox, typhoid and typhus fevers, &c.; together with a full description of the instruments to be used, the method of using them, and practical rules for recording observations.

TEMPERING METALS. A peculiar effect is produced upon some metals by heating them to redness, and then suddenly cooling them. By this means extreme hardness is obtained, especially in steel, which is so susceptible to this process, called tempering, that almost any degree of hardness and brittleness can be obtained. If, for instance, we make a piece of steel red hot, and then plunge it into cold water, it becomes hard and brittle when cold, and is actually, though slightly, increased in bulk. But if we reheat the metal, and allow it to cool slowly, it again becomes soft and malleable as before. Moreover, if we again reheat it, but not to redness, and cool it suddenly, it is still further softened. If, before reheating, the surface has been polished, a beautiful shade of color is produced by the heat, which is varied according to the temperature employed; and so exactly is this the case, that the experienced manipulator is entirely guided by the color produced, instead of by nice regulations of the heat applied. For ordinary operations, the metal is cooled by plunging it in cold water; but oil, mercury, and saline solutions are used for special purposes. An exact series of experiments has proved that the following colors are produced at the temperatures given: Very pale yellowish, by 430° Fahr.; pale straw, 450°; yellow, 470°; brown, 490°; mottled brown. 510°; purple, 530°; bright blue, 550°; blue, 560°; dark blue, 600°.

TE'MPLARS, KNIGHTS, a celebrated religious and military order, founded at Jerusalem in the beginning of the 12th c., by Hugues de Paganes, Geoffroy de St. Omer, and seven other French knights, for the protection of the Holy Sepulchre, and of pilgrims resorting thither. Baldwin II., king of Jerusalem, bestowed on this order their first place of residence; and an additional building was acquired from the abbot and canons of the church and convent of the Temple, whence the order obtained the name of the 'Poor Soldiers of the Temple of Solomon,' afterwards abbreviated into Templars. The knights were bound by their rule to hear the holy office every day, or if prevented by their military duties, to say a certain number of paternosters instead; they were to abstain from flesh four days in the week, and from eggs and milk on Fridays. They might have three horses and an esquire each, but were forbidden to hunt or fowl. In the earlier period of their history, the Templars made a great show of poverty, contrasting much with their later condition. After the conquest of Jerusalem by the Saracens, they spread over Europe; their valor became everywhere celebrated; immense donations in money and land were showered on them; and members of the most distinguished families thought themselves honored by enrolment in the order. In every country where they existed, they had their governor, called the Master of the Temple or of the Militia of the Temple. The Templars had settlements in England from an early period. The first was in London, on the site of Southampton Buildings, Holborn; but from 1185, their principal seat was in Fleet Street, still known as the Temple. The round church which bears their name was dedicated by Heraclius, Patriarch of the Church of the Resurrection in Jerusalem, in 1185, and the chancel was consecrated in 1240.

The Templars were at first all laymen and of noble birth. Pope Alexander III., however, in 1162, authorized the admission of spiritual persons not bound by previous vows, as chaplains to the order, who were not required to adopt the military vows. A third class was afterwards introduced, consisting of laymen not of noble birth, who entered as serving brothers, some of them being attendants on the knights, and others exercising trades in the houses or lands of the order. Eventually, many persons became affiliated members without taking the vows, for the sake of the protection afforded them. As the power and prosperity of the Templars increased, so did their luxury, arrogance, and other vices, which gave the French kings a pretext for endeavoring to suppress them, and lay hold of their possessions. Accusations, many of which were absurd and incredible, were brought against them by two members of their own body. Their principal enemy was Philippe IV. of France, who induced Pope Clement V. to accede to a scheme by which the whole members of the order were seized and imprisoned, their lands confiscated, and many of them tried, convicted, and executed for capital crimes. The English Templars were arrested by command of Edward II.; and a council held in London in 1309 having convicted them of various crimes, most of which were probably imaginary, the king seized their possessions. In 1312, the whole order throughout Europe was suppressed by the Council of Vienne, and its property bestowed on the Knights of St. John, to which latter order their English possessions were formally transferred by a statute of Edward II. in 1323.

The habit of the Templars was white, with a red cross of eight points of the Maltese form worn on the left shoulder. Their war-cry was 'Beau séant;' and their banner, which bore the same name, was parted per fess sable and argent. They also displayed above their lances a white banner charged with the cross of the order. Their badges were the *Agnus Dei*, and a representation of two knights mounted on one horse—indicative of the original poverty of the order.—See Addison's *History of the Knights Templars, the Temple Church, and the Temple* (Lond. 1842); A. O. Haye's *Persecution of the Knights Templars* (Edin. 1865).

TE'MPLATE, a mould in wood or metal, showing the outline or profile of mouldings, and from which the workmen execute the moulding.

TEMPLE (so called because the Knights Templars had one of their branches in that part of London), in its connection with the law of England, is a part of the city occupied exclusively by barristers or attorneys, with few exceptions. It is the joint-property of the two Inns of Court (q. v.), called the Societies of the Inner Temple and Middle Temple, each of which has the right of calling persons to the degree of barrister—a privilege shared by the two other Inns of Court, Gray's Inn (q. v.) and Lincoln's Inn (q. v.). The Temple consists of buildings occupied by barristers, who rent the same from the above two societies, who are the private proprietors, and issue their own regulations as to the management of the property.

TEMPLE, SIR WILLIAM, an eminent diplomatist and popular writer, was the eldest son of Sir John Temple, Master of the Rolls in Ireland. He was born in London in 1628, studied for two years at Emmanuel College, Cambridge (where he had the celebrated Dr. Ralph Cudworth for tutor), and at the age of 19, went abroad on his travels. He acquired the French and Spanish languages, and also cultivated his taste for English composition. He entered on public life in 1661, as member for the county of Carlow, in the Irish parliament. In 1665, he was selected to proceed to Westphalia, on a secret mission to the Bishop of Münster; and on his return, he was created a baronet, and appointed resident at the court of Brussels. He was, as Sir James Mackintosh has remarked, the model of a negotiator, 'uniting politeness and address to honesty;' while as a domestic politician, 'in an age of extremes, he was attached to liberty, and yet averse from endangering the public peace.' In fact, the chief aim and desire of this accomplished statesman was to enjoy lettered ease and leisure, apart from all exciting public care and responsibility. His most important diplomatic success was the famous treaty of 1668, known as the Triple Alliance, by which England, Holland, and Sweden bound themselves to unite in curbing the ambition of France. This negotiation was accomplished in five days, in conjunction with the great Dutch statesman, De Witt. At the congress of Aix-la-Chapelle, and at the subsequent treaty of Nimeguen, T. was also a negotiator. He was long ambassador at the Hague, and assisted in bringing about the marriage of the Prince of Orange with the Princess Mary. Charles II. in vain endeavored to prevail upon him to accept the appointment of Secretary of State; but though shunning such arduous duty, he attempted to reform the government, by establishing, with consent of the king, a privy council of thirty persons, by whose deliberations his

majesty promised to be guided in all public affairs. As might have been foreseen, so numerous a council, under such a sovereign as Charles, and in times of such fierce rivalry and faction, proved an utter failure. T. then finally abandoned politics, and retired to the country.

When the Revolution placed William III. on the throne, T. was again solicited to become Secretary of State; but he again refused. The remaining ten years of his life were mostly spent at his favorite seat of Moor Park, in Surrey, where he carried out his schemes of planting and landscape gardening, and realized his early wish for studious retirement. During this period, he had, as secretary and humble companion, the immortal Jonathan Swift, who regarded his stately self-complacent patron with more fear and distrust than affection, but who ultimately became his literary executor. T. died at Moor Park, in January 1699. His collected works form four volumes (Lond. 1814).

As an author, T. is now known chiefly by his historical *Memoirs* and his *Miscellanea*, the latter being a collection of essays on various subjects—as government, trade, ancient and modern learning, gardening, heroic virtue, and poetry. He has been considered one of the reformers of our style; 'the first writer,' says Johnson, 'who gave cadence to English prose.' His style has quite a modern air, and is smooth, copious, and agreeable. He is too pretentious as respects scholarship and learning, and has no weight as a political writer; but he expatiates very pleasantly on foreign travel and country life, on flowers and fruits, on parterres, terrace-walks, and fountains. His epicurean temperament is happily and characteristically displayed in the last words of his last essay. 'When all is done,' he says, 'human life is at the greatest and best but like a froward child, that must be played with and humored a little to keep it quiet till it falls asleep, and then the care is over.' This is taking the battle of life very easily, but it is not in such manner that great men or true patriots are formed.

TEMPLEMO'RE, a market-town of the county of Tipperary, province of Munster, Ireland, is supposed to take its name from a commandery of the Knight's Templars, and is situated on the right bank of the river Suir, 9 miles north of Thurles. Although without manufactures of any note, T. has some considerable share of inland traffic. It is a station on the Great Southern and Western Railway, 79 miles distant from Dublin. The public buildings, one of which is an extensive barrack, are substantial, but without any noteworthy architectural character. The pop. in 1881 was 2800, of whom upwards of 2000 were Roman Catholics.

TE'MPO (Ital. time), the degree of rapidity with which a piece of music is to be executed. The rythmical proportions of notes, as indicated by their form, give them only a relative value, and have no reference to the absolute speed with which the composition should be played. Some compositions require, from their character, a quick lively movement; for others, a slower movement is more suitable; and different terms are used to indicate different gradations of movement. Of these, the principal, beginning with the slowest, are: *Largo*, broad; *larghetto*, somewhat broad; *lento*, dragging; *grave*, heavy, solemn; *adagio*, slow; *andantino*, moving a little; *andante*, moving; *allegretto*, somewhat lively; *moderato*, moderately quick; *allegro*, lively; *vivace*, with vivacity; *presto*, rapidly; *prestissimo*, with great rapidity. These terms are not always used with the precision that might be wished, and sometimes apply more to the character than to the absolute speed of performance. They are often modified by other qualifying words, as *allegro con brio*, lively and with briskness; *allegro appassionnato*, passionately excited. The *tempo* is indicated with more exactness by a reference to the beat of the Metronome (q. v.).

Thus, M.M. ♩ = 120, signifies that 120 beats of the metronome, each representing a crotchet, are to fill up the space of a minute; M.M. ♪ = 60, that 60 quavers are to be performed in a minute.

While the general rule is, that the time of a movement is to be steady and unvarying, cases often occur where a certain part of a composition has to be taken quicker or slower than the rest; this is indicated by such terms as *più vivo*, more lively; or *ritenuto*, kept back; while a return to the original time is expressed by the words *a tempo*. The performer may be required to proceed from one degree of movement to another, not abruptly, but gradually; the terms used to express this are: *rilasciando*, slackening; *ritardando*, retarding; *calando*, calming down; *stringendo*, pressing on; *accelerando*, gradually increasing speed; with some others.

TEMPO RUBATO (stolen time) is the name given to a mode of performance in which a restless character is imparted by protracting one note beyond its proper duration, and curtailing another, so that the aggregate duration of each measure remains unchanged.

TE'MPORAL POWER (OF THE POPE) is a phrase susceptible of two meanings, which are very distinct from each other, and the confusion of which has led to frequent and serious misunderstanding.

I. In one of these senses, it means the sovereign power which the pope possessed as ruler of the so-called PAPAL STATES (q. v.), and which, especially of late years, has been the subject of much controversy. The power which the pope exercised within his own states, although modified in its exercise by his spiritual character, was in substance the same as that of any arbitrary sovereign. The history of its origin and progress, and of the variation of the limits within which it has been acknowledged, is briefly detailed under the head PAPAL STATES. The question as to the necessity or utility of such a power vested in the hands of a spiritual ruler, and even of its lawfulness and its compatibility with his spiritual duties, has been very warmly debated; nor is this controversy of entirely recent origin. Many of the medieval sectaries put forward the principle of the incompatibility of the spiritual with the temporal power in the same person, not only in relation to the pope, but also as to the baron-bishops or other ecclesiastical seigneurs of that age. Such were the doctrines of the Vaudois, of Pierre de Bruis, and above all, of Arnold of Brescia. The last-named of these rendered himself specially obnoxious by the activity and even turbulence with which he propagated this view, and the sentence of death under which he suffered was the penalty of rebellion quite as much as of heresy.

Through the centuries which followed, the anti-papal controversies turned so entirely upon doctrine, that there was little room for the discussion of this question, and it is a mistake to suppose, as has not unfrequently been done, that it entered in any way into the conflict of Gallican and Ultramontane principles. Even the great Gallican champion, Bossuet, not only admitted the lawfulness of the pope's temporal sovereignty, but contended that it was in some sense necessary to the free exercise of his spiritual power, and to the independence of his ecclesiastical government. It was not until the aggression of the French Republic upon Rome, and the annexation of the Papal provinces called the Legations, to the Cisalpine Republic, and afterwards to the kingdom of Italy, by Bonaparte, that the controversy assumed any practical interest. During the later conflict between Pius VII. and Napoleon I., the design which the latter entertained of a still further annexation of Papal territory was one of the main causes of dispute, and still more recently, after the re-annexation of nearly the same portions of the Papal States to the kingdom of Italy, the question once more agitated the entire Catholic world. No formal and authoritative judgment of the Roman Church was pronounced regarding it; but a strong and almost unanimous expression of opinion was tendered to the present pope, Pius IX., in the form of letters and addresses from bishops and others in every part of Catholic Christendom. The tenor of all these is nearly the same. They profess that the possession of temporal sovereignty is no essential part of the privileges of the successor of St. Peter; but they also regard the possession of a sovereignty independent of any particular sovereign, as the means providentially established for the protection of the spiritual independence of the pope, and of the free exercise of his functions as spiritual ruler of the church. The contrary opinion held by some distinguished members of the Roman Church, although regarded with great disfavor, was not formally condemned by a doctrinal decision, nor was any action taken on it in the Vatican Council. The recent annexation of the city of Rome itself to the kingdom of Italy elicited a still stronger expression. The event is noticed in the article PAPAL STATES (q. v.).

II. By the second signification of the phrase 'Temporal Power of the Pope' is understood what would more properly be called the claim of the pope, in virtue of his office, to a power over the temporalities of other kings and states.

This power may be of two kinds, *directive* and *coercive*. In the first sense, it is a claim which no Catholic, consistently with his belief of the spiritual supremacy of the pontiff, can be supposed to deny, as it imports nothing more than that the pope, as supreme moral teacher, has power to instruct all members of his church, whether subjects or sovereigns, in the moral duties of their several states.

If the power be regarded as coercive, it is necessary to distinguish the nature of the coercion which may be employed. That coercion may either consist in the threat or infliction of *purely spiritual censures;* or it may involve temporal consequences, such as suspension or deprivation of office, forfeiture of the allegiance of subjects, and even liability to the punishment of death. Considered in the former sense, the claim must be regarded as a natural consequence of the spiritual headship of the church, which is acknowledged by all Catholics; nor can it be denied that the power to compel sovereigns, by purely spiritual censures, to the fulfilment of the moral duties which their state imposes, is a natural concomitant of the spiritual primacy.

But the papal claim to authority over the temporalities of kings has gone far beyond these limits. From the 10th c. downwards, popes have claimed and have repeatedly exercised a power of coercing kings, and punishing them when refractory by suspension, by deprivation, and by the transfer of the allegiance of their

subjects to another sovereign. This well-known claim has been a subject of controversy in the Roman Catholic Church between the Gallican (q. v.) and Ultramontane (q. v.) schools; and in the Ultramontane school, two different theories have been devised for its explanation. The first and most extreme (which holds the power to be a direct one) supposes that this power was given directly by God to St. Peter and his successors, that the two powers are foreshown by the 'two swords' mentioned in Luke xxii. 38, and that the temporal power is a privilege of the primacy by divine law, equally with the spiritual sovereignty itself. According to the second, or *indirect* theory, the temporal power is not directly of divine institution, but is an indirect though necessary consequence of the spiritual supremacy; and is only given as a means of completing, and, in a corrupt and disorganized state, rendering more efficacious, the work which the spiritual supremacy is directly instituted to accomplish. It was in this latter form that the theory of the temporal power was defended by the great champion of Ultramontanism, Cardinal Bellarmine, and the celebrated Declaration of the Gallican Clergy (*Declaratio Cleri Gallicani*) in 1682 (see GALLICAN CHURCH) was directed against it.

A third view of the temporal power, and one which has found many modern defenders, was propounded by the celebrated Fenelon (q. v.). According to Fenelon's theory, which is generally described as the Historical Theory of the temporal power, the pope does not possess, whether by direct divine appointment, or in virtue of the necessities of his spiritual office, any temporal power whatsoever. But he possesses the plenitude of that spiritual power which is required for the government of the church, and he is empowered to enforce it by spiritual penalties, and especially by excommunication or deprivation of membership of the church. Now, although excommunication and such other penalties, of their own nature, are purely spiritual, yet the religious sentiment of the medieval period, and the awe with which it regarded the authority of the church, invested these penalties with certain temporal effects. See EXCOMMUNICATION.

The penalty of forfeiture of certain civil rights was attached by the law of England, in the case of private persons, to the spiritual censure of excommunication (q. v.). The same penalty was applied by the laws of other countries to the sovereigns themselves; by the law of Spain in the sixth council of Toledo in 638; that of France, as confessed by Charles the Bald in 859; the law of England, under Edward the Confessor, and the so-called Saxon and Swabian codes of Germany. The last-named codes recognize in the pope, in certain specified cases, the right to excommunicate the Emperor himself; and ordain that in case the Emperor should remain for twelve months without being absolved from the excommunication, he shall be deposed. In the appeal of the Saxon nobles to the pope against Henry IV., this law is expressly referred to. The contemporary historians, Paul of Bernried, Lambert of Aschaffenburg, Nicholas Roselli, and others, describe it as the ground of the Emperor's deposition; and even Henry himself, without denying the force of the law, sought his defence solely in a denial of the charge of heresy which was imputed to him. The same spirit of the age is exhibited in the form of oath taken at the coronation of the sovereign in many countries, especially (although not exclusively) in those whose kings—as Roger of Sicily, Peter III. of Aragon, Guiscard of Naples, Godfrey of Jerusalem, and John of England—had made their kingdoms feudatory to the see of Rome; by which the monarch swore to be the protector and defender of the sovereign pontiff and the Holy Roman Church in all their necessities and utilities, and to guard and maintain their possessions, honors, and rights.

From these and similar indications of the public feeling of the medieval time, the advocates of this theory of the Temporal Power infer that orthodoxy and obedience to the pope, in all essential matters of faith and discipline, were by the consent, express or tacit, of sovereigns and of peoples accepted as a condition of the tenure of supreme civil authority—a condition similar in its character and objects to that which forms the basis of the limitation settlement of the succession to the English crown, to the heirs of the Princess Sophia of Hanover, 'being Protestant.' Hence they conclude that the function really exercised by the popes in relation to heterodox or scandalously immoral sovereigns, or oppressors of the church and church liberties, was in itself a spiritual one, and that the civil consequences which it entailed of deprivation or deposition arose, not from the church law, but from the expressed or understood international civil law of the age. This notion of the origin and nature of the pope's power over sovereigns and states may be regarded as the view now commonly received, and it may help to a better understanding of some points of the controversy regarding the celebrated Syllabus. It may be added, that this view is not confined to Catholic writers, but is held by Leibnitz, Pfeffel, Eichhorn, Voigt, Frederick Hurter (while still a Protestant), and others.

On the other hand, it is difficult, if not impossible, to reconcile this theory with the language used by the popes themselves in enforcing their claim to temporal authority, and with the arguments upon which they rest that claim. Nor can it be denied that whatever is said of the cases of the exercise of such a power which occurred in the 12th and 13th centuries, the power continued to be claimed and to be exercised down to and even after the reformation, when it would be idle to suppose that any such such public understanding, if it had existed in the middle ages, had not been revoked, if not by all, at least by those nations which had revolted from the Roman Church.

The history of most of the principal instances of the exercise of this power by the popes, will be found detailed under the separate articles which refer to the particular popes or sovereigns who engaged in the contest of church and state.—See Gosselin's *Pouvoir du Pape au Moyen Age.*

TENA'CITY (Lat. *tenacitas*, power of holding) is that property of material bodies by which their parts resist a force employed to attempt to separate them. It is the result of the attractive forces exerted by the particles of matter upon one another through the infinitesimally small spaces which are supposed to exist between them; hence it differs in different materials, and even in the same material at different degrees of temperature. The practical bearings of the tenacity of solids (especially of wood and iron) are discussed in the article STRENGTH OF MATERIALS; and we shall therefore here only state a few of the conclusions at which Muschenbroek and other experimentalists have arrived regarding the modifications which the tenacity of metals undergoes in consequence of various processes. Forging and wire-drawing increase the tenacity of metals in the longitudinal direction. Copper and iron have this property more than doubled, while gold and silver have it more than trebled by these metals being drawn into wire. Mixed metals have usually a greater tenacity than simple ones. See ALLOY.

TENAILLE, in Fortification (q. v.), a work in low relief, constructed immediately in front of the curtain. It may either have two faces, in a line with the faces of the adjoining bastions, and meeting at the center in a re-entering angle; or three faces, of which two are prolongations of the bastion faces, and one parallel to the curtain. The tenaille must be low enough for the defenders to be safe from the musketry-fire on one bastion defending a breach in the other bastion. This work is of great use in protecting the ditch, covering the postern from the enemy's view, &c.

TE'NANCY AT WILL, in point of Law, means an occupation by a person in the character of a tenant, but for no fixed term other than the will or caprice of the landlord or proprietor. In general, courts are averse to assume a tenant to be a tenant at will, if there are materials to satisfy the description of a yearly tenant. Rent is payable, under a tenancy at will, according to the time of occupation, and the tenancy can be determined by either party at any time. But the tenant is not to be prejudiced by the sudden determination of the tenancy, so that if he has sown the lands, he is entitled afterwards to re-enter the lands, to reap the crops; and, in like manner, he has a reasonable time to remove his furniture.

TENANCY IN COMMON, in point of Law, means a right to hold or occupy lands, or possess chattels, along with another or other persons. In such a case, each has an equal interest; but in the event of the death of either, his share does not go to the survivors, as is the case in Joint Tenancy (q. v.), but to his heirs or executors. Tenancy in common applies to ownership as well as leasehold interests. Though each tenant has as much right to the whole property as the others, yet neither has a definite share set apart to himself exclusively. If one wastes or deals with the property to a greater extent than his share, the others can bring an action against him. Each can at any time compel a severance of the property so that thereafter he may have his own share severally.

TENANCY ON SUFFERANCE differs from a tenancy at will in this, that a tenant at will enters on a good title, whereas a tenant on sufferance has no title, and wrongfully continues. Thus, when the term has ended, and the tenant has got notice to quit, but does not, he continues a tenant on sufferance, and may be ejected at any time, unless the landlord elect to treat him as a tenant in continuation of the former lease.

TENANT FOR LIFE, in English Law, means one who has not the absolute property, but an interest in the property, which ceases with his own life, or the life of another. An estate for life in lands is classed with freehold estates. Where the estate for life depends on the life of a third person, as it is the interest of the tenant that such third person should live as long as possible, frauds are often committed on the reversioner by misrepresenting the fact of such person being alive; hence, to prevent fraud, the reversioner may insist on the third person being produced, failing which he will be taken to be dead. An estate for life is usually created by deed, but there are two legal estates for life—namely, the widow's estate in dower, and the husband's estate by courtesy on his wife's death. As a general rule, a tenant for life of real

estate is entitled to take wood to repair and burn in the mansion of the estate; but he cannot for other purposes fell the trees, nor open mines or pits, though, if these have been already opened, he may carry them on. Sometimes a tenant for life is declared by the deed or will to be tenant without impeachment of waste, in which case he can exercise most of the rights of an absolute owner, except cutting down ornamental timber, or defacing the family mansion. Tenants for life may now apply to the Court of Chancery for leave to raise money to drain the lands and make improvements. When a tenant for life dies between the usual terms for drawing rent, the rent is apportioned between his executors and the party next entitled. A tenant for life is called, in the law of Scotland, a Liferenter (q. v.).

TENANT IN FEE SIMPLE, in English Law, is the old feudal description of one who is absolute owner, the fiction being that all were originally tenants of the crown. A tenant in fee simple has a freehold estate of inheritance, which is the highest degree of property known to the law. There is practically no feudal connection with the crown, and he can alienate or devise the property without the leave or sanction of the crown. A tenant in fee simple has an absolute right to the soil and the mines down to the the center of the earth, and has a right to build as high as he pleases. If he dies, the estate goes to his heirs—i. e., his heirs general; but he has power to devise it to whom he pleases, subject to certain restrictions, in cases where the donee is a charitable corporation or trustee for charitable purposes. See MORTMAIN. A tenant in fee simple is called in the law of Scotland, a Fiar (q. v.).

TENANT IN TAIL. See TAIL, ESTATE.

TENANT-RIGHT. This term is used by tenants to denote the various claims of right which they may maintain against their landlords, such as the right of occupancy not subject to removal; and the right to occupy at a rent not subject to increase on the ground of improvements; it being said to be inequitable to make them pay rent for what they have themselves produced. It is in Ireland that the claims have always had most importance. In Ulster, and in the north of Ireland generally, the equity of them has long been recognized and acted upon. In the south of Ireland, on the other hand, tenant-right was never conceded by the proprietors; while the right of occupancy not subject to removal, has, *de facto*, been enjoyed by the tenants. The non-settlement of the question was long the cause of bitter controversy, and undoubtedly its evil condition was the root of much of the national misery. Owing to the old tenure of land as tribal or clan property, the people of the south of Ireland never received into their minds the notion of 'contracting' with any one as the 'owner' of land. They had the traditional feeling of being themselves the owners; and so much was this feeling a source of agrarian disturbances, that few Irish 'landed proprietors' have ever ventured fully to exercise their rights of property. And in the south, the land was often occupied by the same families from time immemorial, without lease or contract of any kind.

By the Land Act of 1870, the Ulster tenant-right and all corresponding customs received the force of law, and when there was no definite custom, the outgoing tenant became entitled to compensation from the landlord to an amount varying from one to seven years' rent. The act also gave compensation for improvements. The Land Act (Ireland) of 1881 makes most beneficial changes in the position of Irish tenant-farmers. A Land Commission or Court (with sub-courts throughout the country) was established, to which every tenant may have recourse in order to have a 'judicial' rent fixed for a period of fifteen years, at the end of which time the tenant may again apply to the court. During the fifteen years, the tenant cannot be evicted save for the breach of certain conditions, or non-payment of rent, and the rent cannot of course be raised. The tenant's right to sell his tenancy to one person at the best price he can get was recognized; and provision was made for advancing money to tenants willing to purchase their holdings absolutely.

The Irish claim of tenant-right very much resembles that made by the Indian ryots against their zemindars. In India, as in Ireland, until what may be called recent times, land belonged to families or communities, which held themselves to be composed of kindred; but by acts passed by our government, a class of mere tax-collectors have been converted into land-owners, in order to facilitate the collection of the revenue. Hence, there has been in India an agitation very much resembling that which prevailed in the south of Ireland. The ryot claim of tenant-right was made the subject of a suit before the supreme courts of India, when a majority of the judges favored the equitable claim of the ryots. In countries where the people have been trained in notions derived from the Roman or feudal laws, there has been little heard of this species of claim of right, and land has been recognized by the people as being, like other things, a fair subject for contract.

In Scotland and in the north of England, farms are almost always let on long leases, and at such rents as are supposed to repay the tenant the capital which he may lay out in improvements; and the common case is, that the landlord binds himself to pay the tenant a stipulated sum as the value of his improvements, provided that these are found at the end of the lease to be of a certain stipulated value. Over England generally, on the other hand, tenancy can be ended by six months' notice on either side, and the evils incidental to this precarious tenure have been obviated or mitigated solely by the honorable conduct of the English proprietors. It is quite common in England to find that the son has succeeded the father as tenant at will for many generations, often for centuries.

Since the admission of the claim to tenant-right in Ireland, it has been more frequently heard of in the other parts of the United Kingdom, especially in the form of a claim to compensation for permanent or unexhausted improvements made by the tenant. Of the equity of this claim there can be no doubt, and the law might easily be altered so as to admit of effect being given to it. As matters at present stand, there is little inducement for a tenant to improve the land. The law by which the ownership of improvement follows the ownership of land, is in the present condition of things in the highest degree unjust and inexpedient. The tenant's interest in all his improvements ending with his tenancy, he is very unlikely, at least towards the end of his term, to spend anything on the land which will be of benefit to it; and where he is a tenant at will, he is entirely without interest to improve it.

TENA'SSERIM, acquired by Britain after the war in 1825, is the third or southernmost division of British Burmah* (q. v.)—the other two divisions comprising the ancient kingdoms of Pegu and Arracan. On the 31st January 1862, these three maritime provinces were united under one local administration, bearing the name of British Burmah.

T. is a narrow line of coast about 500 miles in length, with a varying breadth of from 40 miles at its southern extremity to 80 miles; the latter distance being measured from the sea-shore at the mouth of the Salwen to the range of mountains on the east that separates T. from Siam. It extends lengthwise from the southern border of Pegu in 17° 50′ N. lat. to near the tenth parallel of N. lat., and from 97° 30′ to 99° 36′ E. long., and has a total area of 46,730 sq. m. T. is divided into six administrative districts besides the town of Moulmein: Toungu, area 6354 sq. m.; Schwe-gyen, 5567 sq. m.; Salwen, 4646 sq. m.; Amherst, 15,193 sq. m.; the town of Moulmein, 10 sq. m.; Tavoy, 7200 sq. m.; and Mergui, 7760. The principal town is Moulmein; the next in importance being Toungu and Mergui.

Physical Features.—The general aspect of the country is bold and picturesque. The numerous wooded ranges of hills take generally a course from north to south. The northern part of the country is the most level; the southern portion is little else than a wilderness of thickly-wooded hills, enclosing long and narrow leys. The soil of the plains is very fertile, and suited to the growth of rice, indigo, cotton, sugar, and vegetables. Tobacco grows chiefly on the banks of rivers in the hills. Only about $\frac{1}{18}$th of the country is under cultivation, and the forests occupy two-thirds of the entire area. The chief rivers are the Salween, Gyne, Attaran, Yé, Tavoy, and Tenasserim. The Tenasserim, from which the country derives its name, is the most considerable river of the province. The principal ports of T. are Maulmain (q. v.), Amherst, Tavoy, and Mergui, of which Maulmain is the best. Amherst harbor, at the mouth of the Salween, affords good anchorage for ships of any draught of water, but is difficult of approach. The Mergui Archipelago, lying off the southern coast of T., consists of almost innumerable islets, some of which are said to be rich in iron ore; and they are famous for their edible birds' nests. Numerous anchorages are found amongst the islands. The country possesses vast stores of mineral wealth, which now lie absolutely neglected. Gold-washing has been pursued with success at the head of the Tavoy River. At Kahan, on Mergui Island, are rich and accessible tin-mines; and thousands of tons of good clean ore, yielding 75 per cent. of the pure metal, could be raised not far from the surface of the ground. A very productive iron ore is obtained from Iron Island, between Tavoy and Tiger Island. Mergui province furnishes a valuable lead ore, and has extensive fields of coal. Manganese has been found on the Tenasserim River, where it is believed to be very plentiful.

Botany.—The botanical productions of T. may vie with those of any part of the world. There are more than one hundred different kinds of timber-trees, of which the teak is the most important. The celebrated *Amherstia nobilis* is the most splendid of the many flowering and ornamental trees for which T. is famous. The palm tribe are in great variety, and Dr. Griffith collected 1700 different species of plants in about 14 months.

The *climate* of T. is regulated by the monsoons; and the wet

* The provinces of British Burmah extend along the eastern shore of the Bay of Bengal from the Naf Estuary, in about 20° 50′ N. lat. to the Pak-chan River in about 10° 15′, with a coast line of 900 English miles. Their area and population, according to the latest returns (1872), are as follows: Arracan, area 14,526 sq. m., pop. 481,363; Pegu, area 27,300 sq. m., pop. 1,662,058; Tennasserim, area 46,730, pop. 600,727.

and dry seasons divide the year into two nearly equal parts. The average yearly fall of rain is about 194·28 inches, and this descends during the six rainy months from May to October. The greatest amount of rain ever recorded as having fallen in one day (27th May 1857) is 12·75 inches; and the gauge for the week registered 40·27 inches (Dr. Walter). While the rains last, the temperature is very uniform, the thermometer ranging between 76° and 82°. The cool season lasts from the cessation of the rains in October, when the north-east monsoon begins, to the middle of February. During that time, the thermometer seldom reaches 90° in the shade, and occasionally falls as low as 56°, and now occurs the greatest thermometric range, which is sometimes as much as 30° in one day. The sun then gradually regains its power, and the heat increases daily till the south-west monsoon again brings clouds and rain. In the hot period, the thermometer at mid-day is not often below 92° in the shade, and not unfrequently stands at 95°.

Commerce.—The principal exports from T. are teak, timber, and rice. The trade of the province is, however, not on the increase. The first two articles of export mentioned are not continuous from year to year; and we accordingly find that the decrease in the value of trade is owing to the diminished demand for teak timber. Indeed the defective continuity of supply is to some extent a fact also as regards timber. Rice is the most reliable article of commerce.

Inhabitants.—In 1872 the pop. of the T. districts was as follows: Toungu, 86,166; Schwe-gyen, 129,485; Salween, 26,117; Amherst, 193,468; Moulmein (town), 46,472; Tavoy, 71,827; Mergui, 47,192; total pop. of T., 600,727. Most are Burmans proper, but there are other races, as Talaings, or descendants of the ancient Peguans; Karens, a dispersed people, inhabiting secluded mountain districts —among whom Christianity has made some progress, through the labors of American missionaries; Toungthoos, Khyengs, Shans, Europeans and their descendants, Chinese, and Indians. Throughout T. and British Burmah generally, inheritance and marriage are regulated by Buddhist law, while at the seaports the English mercantile law and law of contracts are in force, and regulate the decisions of the courts.—*The Natural Productions of Burmah and the Tenasserim Provinces*, by the Rev. F. Mason, A.M. (Maulmein, 1850); *Six Months in British Burmah*, by Christ. T. Winter (Lond. 1858); *The Tenasserim and Martaban Directory* (Maulmain, 1857); *Reports of the Administration of the Province of British Burmah, for* 1861, 1862, *and* 1863, by Lieut.-colonel A. P. Phayre, C.B., Chief Commissioner and agent to the Governor-general (Rangoon, 1862, 1863).

TE'NBY, a small parliamentary and municipal borough, and thriving watering-place, of South Wales, in the county of Pembroke, and 10 miles east of the town of that name. Its charming situation on a peninsula, overlooking the Bay of Caermarthen, its salubrity of climate, and the facilities for bathing which the extensive sands in the vicinity afford, have made it one of the best and most fashionable watering-places in Wales. A considerable part of the ancient embattled walls of the town still remains. There are also a handsome church and picturesque ruins of a castle. The season lasts from June till October, and the number of permanent winter residents is annually increasing. Fishing is extensively carried on. Pop. (1881) 4783; but during the season the number is greatly increased.

TENCH (*Tinca*), a genus of fishes of the family *Cyprinidæ*, of a thick form, with small scales, and a barbel at each side of the mouth, the teeth on the pharynx compressed and club-shaped. The COMMON T. (*T. vulgaris*) is an inhabitant of ponds and other

Tench (*Tinca vulgaris*).

stagnant waters in Europe and the north of Asia. It passes the winter in a torpid state, concealed in the mud. It is of a deep yellowish-brown color, more rarely golden or greenish. Instances have occurred of its attaining a length of three feet, but a T. of half that length is unusually large. It is very tenacious of life, and, like the carp, can be conveyed to a distance alive in wet moss. It spawns in May and June, depositing its spawn among aquatic plants. The ova are very small and very numerous. The flesh of the T. is soft and insipid, except when it is very well fed, when it becomes delicate and pleasant. It is commonly placed in ponds along with carp; a much smaller number of T. than of carp, however, being deemed sufficient to stock a pond. In Britain, the T. is found only in England, and there sparingly in some of the slow and muddy rivers. It is not improbable that it may have been originally introduced as a pond-fish, although it has long been naturalized. Angling for T. resembles angling for carp. The same kinds of bait are used.

TE'NDA, COL. DE, a pass over the Maritime Alps. See ALPS.

TENDER, as a Legal term, means the formal offer to perform some obligation incumbent on the person tendering. It is more frequently used in reference to the payment of money which is due. Whenever a tender of the debt is properly made, the legal consequence is this, that if the money is refused, the creditor will have to pay the costs of any action he may bring to recover it, and cannot claim interest afterwards. In case such an action is brought, the debtor has nothing to do but to plead that he duly tendered the money, and if he then pay into court the sum which he had formerly tendered, the other party must stop the action, or continue it at his own risk. In order, however, that a tender should have the above effect, it must have been duly made—that is to say, it must have been made without imposing any conditions on the creditor, and at the proper time and place. The tender must be in money, and not by bill of exchange; but Bank of England notes are a good tender for all sums above £5. If the debt is beyond 40*s*., it ought to be in gold, so far as it goes. Though other bank-notes than Bank of England notes are often tendered, the creditor is not bound to accept them; but if he take them without any specific objection, then it will be a sufficient discharge. A tender of a larger sum than is due is good, but must not require change to be given, which the creditor is not obliged to find. Nor must any consideration be annexed to the tender, not even the condition of giving a stamped receipt, though on other grounds, by statute, a person receiving payment is bound to fill up a stamped receipt on its being tendered to him, and to pay the stamp; and his refusal to fill up the receipt subjects him to a penalty of £10. A tender of payment must, in general, be made to the creditor at the place he has indicated, and it is the duty of the debtor to find out and pay the creditor. With regard to payment of rent, however, it is enough that the tenant be ready to pay the rent on the premises at the time it is due, it being the landlord's duty to send or call for it, for the land is the proper debtor, and that is the place to apply to in the first instance.

TENDER, in Naval language, a small vessel appointed for the service of a larger one. Steam gunboats are most commonly employed as tenders.

TEN'DON is the term employed in Anatomy to designate the white fibrous tissue reaching from the end of a muscle to bone or some other structure which is to serve as a fixed attachment for it, or which it is intended to move. In accordance with their form, tendons have been divided into the three following varieties: (1) *Funicular*, or rope-like, as the long tendon of the biceps muscle of the arm; (2) *Fascicular*, as the short tendon of that muscle, and as the great majority of tendons generally; and (3) *Aponeurotic* or tendinous expansions, sometimes of considerable extent, and serviceable in strengthening the walls of cavities, as, for example, the tendons of the abdominal muscles.

The tendons commence by separate fascicles from the end of each muscular fibre, and they similarly terminate by separate fascicles in distinct depressions in the bones, besides being closely incorporated with the periosteum. In some birds, whose tendons are black, the periosteum is black also, from this incorporation. If a tendon is ruptured by an accident, or divided by the surgeon, the two ends, if not too far separated, unite with extreme readiness, by the formation of intervening plastic material, which soon acquires great firmness. So rapidly is this process of repair carried on, that, according to Mr. Paget, a specimen, six days after division, could bear the weight of 25 lbs.; while in another specimen, the new material, at the end of 21 days, bore a weight of 56 lbs. When the interval between the two ends of a tendon exceeds a certain limit, there will be only an imperfect bond of union, and either a partial or total loss of the use of the muscle will result. For details regarding this process of repair, which has an intimate bearing on the treatment of ruptured tendons, the reader is referred to Mr. Paget's admirable *Lectures on Surgical Pathology*.

Amongst the diseases of tendons, *inflammation* requires especial notice. 'Tendons,' says Mr. Tatum, in his article upon *Affections of the Muscular System*, 'together with their sheaths, are not unfrequently inflamed. Independently of gout and rheumatism, the most frequent cause is a sprain or wrench in the neighborhood of a joint. These injuries are occasionally productive of long-continued wearing pains, assuming much of a rheumatic character, and yield often slowly and unwillingly to the remedies, both local and general, employed in rheumatism.'—Holmes's *System of Surgery*, vol. iii. p. 544. In one of the forms of Whitlow (q. v.), known as *Paronychia gravis* or *tendinous whitlow*, 'the tendons and

their sheaths in the finger and hand are the seat of a severe and often most destructive inflammation, which, though often confined to one finger, not unfrequently extends to the hand and arm, attacking not only the tendons and softer parts, but exposing the bones, and disorganizing the joints.'—*Op. cit.*, p. 544. It arises from slight punctures or wounds, with or without the inoculation of irritant or poisonous matter, and often without any apparent cause, except a derangement of the general health. It begins with severe and throbbing pain in the palmar surface of a finger, which extends upwards along the arm. There is extreme tenderness, and a certain amount of redness and swelling, with great tenseness of the parts. If the inflammation is not checked, suppuration soon ensues, accompanied by much constitutional disturbance. The matter frequently extends amongst the muscles, and in bad cases, occurring in unhealthy persons, the bones and joints become affected in the way already mentioned. In the early stage, free leeching, followed by hot fomentations, may be useful. The hand should be kept elevated, and an active purgative, with low diet, prescribed. If, as is often the case, these measures are unsuccessful, a free incision must be made along the center of the palmar aspect of the finger—an operation which gives extreme relief, by removing the tension, and allowing the escape of blood, even if little or no pus is discharged. A generous diet, stimulants, and tonics, are now advisable; and under this treatment the disease generally yields; although cases occasionally present themselves in which the suppuration produces such results as to render amputation of the arm necessary, or even to cause death. A permanently bent finger, from adhesion of the tendon to its sheath, is a common result in severe cases of whitlow of this kind.

Tendons are not very unfrequently the seat of syphilitic enlargements or tumors. Malignant tumors scarcely ever spring from tendons, but fibrous tumors and small cartilaginous enlargements are often found in tendons.

Rupture of the tendons is an accident which is frequently caused by violent muscular action, especially if, from illness or other causes, the muscles have been for some time in a state of inactivity. The long tendon of the biceps cubiti is very obnoxious to this injury, which, in this case, is more often due to the disorganization caused by chronic rheumatic gout than to mere mechanical violence. The other tendons most frequently ruptured are the tendo Achillis, and the tendons of the rectus femoris and the triceps humeri. When a tendon is ruptured or divided by a surgical operation (tenotomy), 'the part which is attached to the muscle is drawn away from the opposite end for about an inch. Blood is poured out between the ends, but much less than in rupture of muscles. The pain is said not to be very great; a considerable shock, however, is felt, as from a blow received on the part, accompanied by cramp of the muscle, and a perfect inability to use the limb; and in rupture of the tendo Achillis, a feeling is described as if the heel were sinking into a hole in the floor.'—Holmes's *System of Surgery*, vol. iii. p. 541. The essential point in the treatment of ruptured tendon is to keep the injured part in a state of constant rest and muscular relaxation, so that the separated ends may be approximated as much as possible, and to prevent any violent extension till firm union, by the process of reparation, has been established. The special methods of treating individual cases (as rupture of the tendons of the rectus femoris and the triceps, and of the tendo Achillis) are discussed in Holmes's *System of Surgery*, and other standard works on surgery.

TENE'BRIO. See MEAL-WORM.

TE'NEDOS (Turk. *Bogdsha-Adassi*), an island belonging to Turkey in the north-east of the Ægean Sea, off the coast of the Troad, and about 17 miles south of the western entrance to the Strait of the Dardanelles. It is about five miles long by two broad, rocky, but not unproductive, with a pop. of more than 6000, who are partly Greeks and partly Turks. The chief town, also called Tenedos, or *Bogdsha*, has a trade in wine. Opposite T., on the coast of Asia Minor, is the bay of Besika, whither the English fleet was sent in 1877.

TENERI'FE, the largest of the Canaries (q. v.).

TENERIFE, PEAK OF, or PICO DE TEYDE, a famous dormant volcano, the highest summit in the Canary Islands, stands in the south-west of the island of its own name, and is 12,182 feet above sea-level. The lower slopes of the mountain are covered with forests, or laid out in extensive meadows, yielding rich grass; but the upper ridges, and the Peak, properly so called, are wild, barren, and rugged in appearance. The Peak and its two inferior neighbors, the *Montana Blanco* and *Chajorra*, rise from a rugged circular plain of lava debris and pumice, 7000 feet above sea-level, about 8 miles in diameter, and fenced in on all sides by an almost perpendicular wall of rock. From the crevices of these mountains sulphurous vapors are constantly exhaling. The Peak can be seen from a distance of upwards of 100 miles; but the view from it is generally destroyed by the dense masses of cloud which hang over the surrounding sea at an average elevation of 4000—5000 feet, the sky above being almost uniformly clear and bright. Mr. Piazzi Smyth, in the summer and autumn of 1856, made here a series of experiments for the purpose of ascertaining how far astronomical observation could be improved by eliminating the lower third part of the atmosphere, and with this object observed for two months, first on Guajara (an elevated peak of the rocky wall, 8903 feet high), and afterwards on Alta-Vista (on the side of the Peak, 10,702 feet high). See *Tenerife*, by C. Piazzi Smyth (London, 1858).

TENÈS, a rising seaport of Algeria, 100 miles west of the city of Algiers. It is happily situated for commerce, is the entrepôt for Orleansville, and the depot for the supply of the army with provisions. It is at once fortunate in the agricultural resources of its territory, in its mineral wealth, and its position in respect to transit-trade. Pop. (of commune in 1871) 8000.

TENE'SMUS (from the Gr. *teinein*, to strain) is the term employed in Medicine to designate a straining and painful effort to relieve the bowels when no fæcal matter is present in the rectum; the effort being excited by some adjacent source of irritation. All that is got rid of by the straining, which usually occasions more or less descent of the gut, is mucus, frequently stained with blood. Tenesmus is a common symptom in dysentery, irritation of the bladder, stricture of the urethra, &c.

TENIERS, DAVID, the Elder, a Flemish artist of note, was born at Antwerp in 1582. For some years, he was a pupil of Rubens; afterwards he visited Italy, where he studied under Adam Elzheimer, and on his return, settled in his native city, where he died in 1649. The subjects of T.'s pencil are in general very homely, and often low—the interiors and exteriors of public-houses, smoking-rooms, rustic games, weddings, &c.; but they are executed in the most vividly realistic manner, with such charm of color, and happy ease of composition, that they never fail to excite in the beholder a lively sense of pleasure. T. was almost constantly employed during his career as an artist.

TENIERS, DAVID, the Younger, son of the preceding, was born at Antwerp in 1610. He received his first lessons in art from his father, who, it is said, subsequently placed him in the studio of Adrian Brauwer; but this statement can scarcely be true, for Brauwer (q. v.) was only two years older than himself. It is probable that he derived most, if not all his professional instruction from his father, to whose genius his own bore a peculiarly filial resemblance. In fact, the elder T. may be considered the founder of a school of which the younger is the most brilliant and prolific member. The latter, like his parent, rapidly rose into distinguished consideration, enjoying in the course of his life the favor and friendship of the Archduke Leopold, Queen Christina of Sweden, Don John of Austria, the Prince of Orange, the Bishop of Ghent, and other dignitaries. T. lived for the most part in a villa on the outskirts of Malines, where he had abundant opportunities of studying closely that humble rustic life which he has so charmingly depicted in all its aspects; but he died at Brussels, 11th February 1685. He was twice married: first to a daughter of the painter Breughel (q. v.), *Velvet* Breughel as he was called; and again to the daughter of a councillor at the court of Brabant. The number of his pictures is something marvelous. Smith, in his *Catalogue Raisonné* has carefully described 685. England is peculiarly rich in specimens, but they are also liberally scattered over the galleries and private collections of the continent, and, in spite of their number, bring great prices. They possess, but in a superlative degree, the beauties of the elder T.'s pieces. In the coloring of his skies, the sketching of his trees, the animation and grouping of his figures, we see everywhere the presence of a richer, finer, more observant and more imaginative genius.

TENNANT, WILLIAM, still to be remembered as the author of *Anster Fair*, was born at Anstruther, in Fife, in the year 1785. A cripple almost from his birth, and doomed to propel himself through life on crutches, he betook himself naturally to study, as requiring no exertion of the limbs. In 1799, he went to the neighboring university of St. Andrews, where, however, he only remained two years, leaving it to join his brother, a corn-agent in business. In this, his success was indifferent; and in 1813, he was fain to accept the situation of parish schoolmaster at Dennino, a small hamlet about four miles from St. Andrews, with a salary of £40 a year. The year before, he had published his *Anster Fair*, a poem of much sprightliness and humor, notable as the first attempt to naturalize in our language the gay *ottava rima* of the Italians; by Byron, soon after adopted with such splendid success in his *Beppo* and *Don Juan*. The piece gradually made its way, and in 1814, a highly laudatory notice of it appeared in the *Edinburgh Review*, from the pen of the then omnipotent Jeffrey. In 1816, Mr. T. became teacher of a school at Lasswade, near Edinburgh, whence, three years afterwards, he transferred his services to the Academy of Dollar, in Clackmannanshire. His attainments as a linguist were extraordinary; and in 1835 he was ap-

pointed Professor of Oriental Languages in the university of St. Andrews—a post for which, perhaps, not many men then living had similar qualifications. In connection with his new duties, he published, in 1840, grammars of the Syriac and Chaldee languages. He died, on 15th February 1848, at his residence near Dollar, where his summers were usually spent. He was one of the most genial and amiable of men. Besides other miscellanies in verse, he gave to the world, in 1822, *The Thane of Fife, a Poem;* in 1823, *Cardinal Beaton, a Tragedy;* and in 1825, *John Baliol, a Drama.* None of these later productions had much success, or did anything to increase the literary reputation which his first work had won for him.

TENNESSEE′, a southern state of the American Union, the third admitted under the federal constitution, extends in lat. 35° —36° 30′ N., and long. 81° 37′—90° 28′ W., and is bounded on the N. by Kentucky and Virginia; and on the S. by Georgia, Alabama, and Mississippi. Area, 45,600 square miles. The chief towns are Nashville, (the capital), Memphis, Knoxville, Chattanooga, Murfreesborough, and Jackson. The principal rivers are—the Mississippi, forming the boundary on the west; the Cumberland (q. v.); the Tennessee River, which twice crosses the state; the Obion, Hatchee, and numerous branches of the larger rivers, which give navigation and water-power to the entire state. Eastern T. is crossed by several ridges of the Alleghany Mountains, some of which have elevations of 2000 feet; the middle region between the Cumberland and Tennessee rivers is hilly, and the west level. The western portion of the state, between the Mississippi and the Tennessee, is of the alluvial and cretaceous formation of the shores of the Atlantic and Gulf of Mexico. Extensive iron mines lie between the Tennessee and Cumberland rivers. In the limestone regions are numerous caves, mostly unexplored. Several in the Cumberland Mountains are 100 feet deep, and miles in extent. A considerable river has been discovered in one at a depth of 400 feet; another opening perpendicularly in a mountain has never been fathomed. In some of these caves are large deposits of fossil bones of extinct animals. In the Enchanted Mountain are seen impressions of the feet of men and animals in limestone. Tracts of several acres have sunk into caverns a hundred feet deep. In many places are interesting remains of ancient mounds and fortifications.

The climate of T. is temperate, and, except in some of the river-bottoms, salubrious. The soil of the whole state, except the eastern mountainous regions, is extremely fertile, producing cotton, tobacco, Indian corn, wheat, figs, peaches, grapes, and all the fruits and productions of the southern temperate regions. The state is richly wooded with pine, oak, hickory, sugar-maple, cedar, black walnut; and the woods abound in game, as bears, deer, opossums, raccoons, foxes, &c.; and the country is rich in horses, cattle, sheep, and swine—the last running in large herds in the woods, and fattening on nuts. The state debt at the end of 1880 was near $27,000,000; the state receipts are about $650,000 yearly. In 1879, the crops of T. included 50,897,500 bushels Indian corn, 11,852,000 bushels wheat, 44,160,000 lbs. tobacco, and 204,457,000 lbs. of cotton. In 1870 there were 21,465,452 lbs. tobacco, and 181.842 bales cotton. The commerce of the state, by its rivers and 23 lines of railway, is chiefly with New Orleans, St. Louis, and Cincinnatti. There are state asylums for deaf and dumb at Knoxville, and for the insane and blind at Nashville. There are 51 colleges; a common school-fund of $2,500,000; 2842 churches, chiefly Methodist, Baptist, and Presbyterian; 9 daily, 110 weekly papers. The value of property in 1879 was above $222.000.000.

In 1756, a settlement was formed near Knoxville, then a part of North Carolina. Nashville was settled near the close of the Revolution; in 1790, T. was organized as a territory with Kentucky; and admitted, in 1796, into the Union as a separate state. In January 1861, a proposal to secede from the Union was defeated; but in June, carried by a majority of 57,667. In ten months, the state raised 50 regiments for the Confederacy; while 5 or 6 were also recruited for the Union. The state was the scene, at Knoxville and Chattanooga, of some of the most important operations of the war. T. sends 8 representatives to congress, in addition to the 2 senators allowed to each state. For some years after the civil war, portions of T. continued in a very disturbed condition, numerous outrages being committed by bands of disguised marauders. Population (1800) 105.602; (1820) 422,813; (1840) 829,210; (1860) 1.109,847; (1870) 1,258,373; (1880) 1,542,461; (1,139,-129 whites. 403,343 colored).

TENNESSEE, a river of the United States, the largest tributary of the Ohio, has its origin in the union of the Clinch and Holston, which rise in the Alleghany Mountains of South-western Virginia, and flowing south-west in two parallel valleys, unite at Kingston in the west of Tennessee state. The river flows still south-west, in the Alleghany valley, entering Alabama close by the north-west corner of Georgia, whence it flows 60 miles further in the same course, then turning to the west-north-west, re-enters Tennessee at the north-east corner of Mississippi, flows northwardly across the state, then north-west across Kentucky to its confluence with the Ohio at Paduca; length 800 miles, or from the source of the Holston, 1100. Its chief branches are the Sesquatchie, Paint Rock, Flint, Duck, North Branch, Hiawassee, Big Sandy, and Clark's. It is navigable 259 miles to Mussel Shoals—a series of broad shallow rapids—and 500 miles above. Chief towns, Florence and Decatur, in Alabama; and Chattanooga, Tennessee.

TE′NNEY, in Heraldry, orange color, one of the tinctures enumerated by heralds, but not of frequent occurrence in coat-armor. It is indicated in engravings by lines in bend sinister, crossed by others barways.

TE′NNIS, a game of great antiquity, belongs to the class of ball-games, and finds its analogies in the *sphairisis* of the Greeks, and the *pila* of the Romans. Under the name of *paume*, a name given to it from the ball being at that time struck with the palm of the hand, it is noticed in the Arthurian romances, and in the earlier records of the dark ages. In the 15th c. it was in great vogue in France among all classes, from the monarch to the meanest of his subjects; and about this time the use of a heavy glove to protect the hand in striking the ball was introduced, and a further improvement was subsequently effected by the adoption of the *racket*. The game in England kept pace with its progress in France, and during the 16th, 17th, and 18th centuries, was generally practised under the name of *tennis*. Many modifications have been introduced, but the legitimate descendant of the paume and tennis of former days is the present game of rackets. (See LAWN TENNIS.) 'Rackets' is played in a court 96 or 97 feet long, by 33 or 34 feet wide, and surrounded by walls sufficiently high to prevent the ball from being lost. The players are either two in number, or four divided into two parties. The player or party 'in' *serves* the ball against the head-wall of the court, so as to rebound over a line drawn at a certain distance; it is returned by means of the racket by the player or party 'out,' who must make it rebound from the wall to the other side of the line; and the game is thus carried on till one player fails to strike the ball or cause it to rebound properly. If the player 'in' fails, he changes places with the player 'out;' if the latter fails, the former scores a point. The part of the court on which the player or party in is placed is called the 'service' side; the other, the 'hazard' side.' A similar game played without the racket is called *fives*, *hand-tennis*, or *hand-ball*.

TENNYSON, ALFRED, was born in the year 1809 at Somersby, in Lincolnshire, of which parish his father was rector. He was the third of a large family, several other members of which shared with him in some measure the genius which has won for him undisputed rank as the first English poet of his time. Very early, the bent of nature became obvious; and in 1827, T., along with his brother Charles, issued a small volume, entitled *Poems by Two Brothers*, of which almost nothing has been preserved. Having gone to complete his education at Trinity College Cambridge, he gained in 1829 the Chancellor's Medal by a poem in blank verse, entitled *Timbuctoo*, in which there is plainly to be traced some impress of his peculiar genius. His literary career, however, may properly be said to date from 1830, in which year a volume appeared of *Poems, chiefly Lyrical*, by Alfred Tennyson. It was not received with great favor by the public; but amid much that was weak and immature, it contained pieces which in no indistinct manner announced the advent of a true poet. In a notice of the book by Professor Wilson, in *Blackwood's Magazine*, the promise of the young writer was recognized in sufficiently express terms. The praise was, however, not unmixed with censure, which, though it seemed on the whole judicious, did not commend itself as such to the poet, who retaliated on 'crusty Christopher' in his next volume, published in 1833. This consisted of a selection of poems from the previous one, carefully retouched by the writer, with the addition of pieces produced in the interval, many of which have scarcely been surpassed in beauty by anything he has since produced. Onward from this time, the reputation of the writer slowly but surely extended itself; and the publication, in 1842, of *Poems, by Alfred Tennyson*, in two volumes, raised him to the position of absolute supremacy which he has ever since continued to occupy by almost universal consent. In 1847 appeared *The Princess, a Medley;* and in 1850, the series of elegies entitled *In Memoriam, A. H.*, a tribute of affection to the memory of Arthur Hallam, a son of the eminent historian, and the chosen friend of the poet in his earlier years at Cambridge.

On the death of Wordsworth, in 1850, T. succeeded him as poet-laureate, in which capacity he issued, in 1852, his *Ode on the Death of the Duke of Wellington*. In 1855 appeared *Maud, and other poems*. The immediate reception of this little volume was not enthusiastic. While many of its lyrics instantly caught the public ear, *Maud*, as a whole, at first rather puzzled the critics, and was little better than 'caviare to the general;' and though it has since risen in estimation, the subtle and recondite art exhibited in the structure of the poem is probably even now appreciated by only a few of

its admirers. But for any little falling off in T.'s popularity on this occasion, a noble *amende* was made him on his next appearance. *The Idylls of the King*, published in 1859, were everywhere received with enthusiasm. With scarce a whisper of dissent, this work at once took rank as one of the noblest poems in our language. It was followed in 1864 by a volume, containing *Enoch Arden*, one of his most finished and successful works; *Aylmer's Field;* a short piece, *Tithonus*, consummate in its beauty and finish; and a few other poems of a somewhat less elaborate character; one of which, however, *The Northern Farmer*, written in the Lincolnshire dialect, is singularly striking. Since then, T. has given us several new *Idylls*, which may be considered to complete his handling of the Arthurian romance: *The Holy Grail* and *Pelleas* and *Ettarre* (1869); and *Gareth and Lynette*, and *The Tournament* (1872). *The Window* appeared in 1870; the *Lover's Tale*, in 1879; and *Ballads*, &c. in 1880. In 1875 he published his first drama, *Queen Mary*, followed by *Harold* in 1876; *The Falcon* was acted in 1879; *The Cup*, in 1881; and *The Promise of May*, in 1882. Recent collected editions arrange the various *Idylls of the King* in the order, not of their publication, but of their proper sequence in the legend of Arthur, and enable the reader to appreciate the full beauty and significance of the ideal story. T.'s biography, even more than that of most authors, is given, so far as the public is concerned with it, in the simple enumeration of his works. He has lived for the most part a retired life in the Isle of Wight, or at Haslemere in Surrey.

It is not an easy matter to criticise the poetry of T. dispassionately, so deeply is one apt to become enamored of its beauties. His verse is the most faultless in our language, both as regards the music of its flow and the art displayed in the choice of words. Nowhere in literature is the *callida junctura verborum* so wondrously seen. As a painter, no modern poet has equalled him. But it is neither to his color nor to his music alone that he owes his great popularity. His *virtue* as a poet doubtless lies in these things; but the pleasure which his poetry gives springs largely from the cordial interest he displays in the life and pursuits of men, in his capacity for apprehending their higher and more beautiful aspirations, and in a certain pervasive purity and strength of spiritual feeling.

TE'NON, in Carpentry, the square end of a timber, reduced about ⅓d its thickness, to fit the mortise or socket in another timber, so as to join the two.

TENOR, in Music, one of the four classes into which voices are divided in respect of their compass. It is the higher description of adult male voice, and generally extends from

 Music for tenor voices is most properly written on the tenor or C clef, in which its principal tones come within the staff; but the treble clef is occasionally used, with the notes written an octave above their true pitch.

TENO'TOMY, or the Division of Tendons, is a comparatively recent surgical operation, whose object is to relieve some variety of deformity by severing a permanently contracted muscle at its tendinous portion. The invention of subcutaneous tenotomy is due to Stromeyer (1831), and a lucid account of the history of this operation is given by Dr. Little in his *Treatise on Club-foot and Analogous Deformities* (Lond. 1839). The various kinds of knives that have been devised for severing tendons are termed *tenotomes*. The affections in which tenotomy is advantageously employed are club-foot, contractions of the upper extremity from spasm and paralysis, deformity from diseases of the palmar fascia, torticollis or wry-neck, anchylosis of the knee and other articulations, and squinting.—For further details, the reader is referred to the above-mentioned work by Dr. Little, and to the same author's treatise *On the Deformities of the Human Frame* (Lond. 1853).

TE'NREC or TANREC (*Centetes*), a genus of Mammalia, nearly

Tenrec (*Centetes ecaudatus*).

allied to moles and hedgehogs, usually ranked in the family *Erinaceidæ*. The tenrecs are incapable of rolling themselves up like hedgehogs. They are nocturnal animals, natives of Madagascar and the Mascarene Isles. Three species are known. They are remarkable for spending the hottest part of the year in a dormant state, as some animals in arctic regions spend the winter. Their flesh has a very peculiar flavor, but is acceptable to the natives of Madagascar.

TENSE (Fr. *temps*, from Lat. *tempus*, time), in Grammar, designates a set of changes which verbs undergo in order to mark the time of the action. See CONJUGATION.

TENT (Lat. *tentorium*, from *tentus*, stretched). Without speculating on the relative priority of tents and other forms of human dwellings, it is safe to assume, that among nomadic tribes, some shelter easily framed and portable, must have been felt to be a

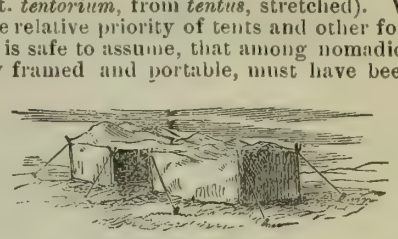

Fig. 1.—Arab Tent.

primary necessity. The skins of animals, or the larger kinds of foliage, would form the earliest coverings, for which textile fabrics would be substituted as civilization advanced. In the book of Genesis, the patriarchs, Noah, Abraham, Lot, Isaac, Jacob, are represented as dwelling in tents, probably much the same as the modern Arab tents, which are large structures, very rude in form, covering a considerable space of ground, but of small height. Among the Nineveh sculptures is a representation of the tent of King Sennacherib, which, like modern tents, was supported by ropes: numerous tents of the officers and common people are likewise shown.

The early Greek, and afterwards the Macedonian tents were small coverings of skins, under each of which two soldiers slept. Alexander the Great is said to have had a pavilion of extraordinary magnificence. Its roof, one mass of gilded embroidery, was sustained by eight pillars covered with gold. In the center, was the royal throne; and 100 beds could be made up within the temporary edifice.

The Roman soldiers seem to have used two sorts of tents—one, a tent proper, of canvas or some analogous material, and con-

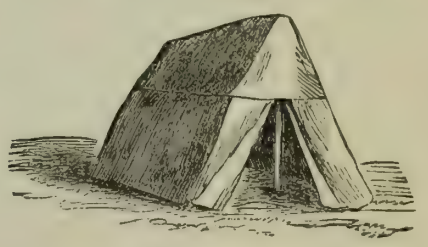

Fig. 2.—Roman Tent.

structed with two solid upright poles, and a roof-piece between them; the other, more resembling a light hut, of a wooden skeleton, covered by bark, hides, mud, straw, or any material which afforded warmth. Of these tents, the poles of the first would have been too cumbrous for carriage, and were probably cut afresh at each halting place; the latter was evidently unsuited to removal, and was most likely only erected for winter-quarters or a long sojourn. The Roman tent held 10 soldiers, with their *decanus*, or corporal.

In Persia, there are many tribes who pass their whole time in tents, which, naturally, they have brought to considerable perfection. They make them nearly hemispherical, with a wooden frame-work, and covered with felt, while worked hangings close the aperture. This felt admits of the exhibition of much taste in its decoration.

The Chinese lower orders live much in tents. They are ordi-

Fig. 3.—Chinese Tent.

narily of matting. These people are clever in their construction, and make them of great size, and with considerable comfort.

Modern military tents are all made of linen or cotton canvas, supported by one or more poles according to shape, and held extended by pegs driven into the ground. British tents comprise

Fig. 4.—Bell-tent.

the hospital-marquee, a large oblong tent with high side-walls; and the round-tent, or bell-tent, for troops. The latter is 12 feet 6 inches in diameter, 10 feet 4 inches high, weighing, with all its appurtenances, 68 lbs., and giving sleeping accommodation to 16 men; the appurtenances comprise 2 mallets, 50 pins, 20 ropes, 20 loops, and 2 long ropes, for use in storms in giving additional firmness round the central pole. In modern tents, there is a low side-wall of canvass, to give greater room inside. These tents are said to be comfortable and moderately healthy, if floored with tarpaulin, vulcanized india-rubber, or other waterproof material. The great drawback is the tendency to blow over. To obviate this, and the inconvenience arising from the conical shape, Major Rhodes, a British officer, invented some years ago a new tent,

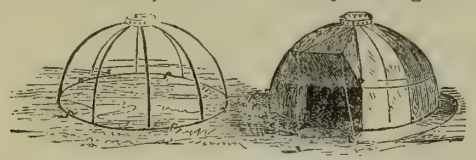

Fig. 5.—Major Rhodes's Tent.

which has found much favor both in this and in other countries. He does away with the central pole, and has a circular frame, hingeing in the center like the ribs of an umbrella, over which the canvas is stretched. It is claimed for this tent, that it is more roomy than the regulation tent, in proportion to its weight, is better ventilated, and possesses far greater stability.

TENTA'CULITES, a genus of obscure annulated tapering shells, found abundantly in some strata of Silurian age. They are generally referred to annelids, but the structure of the shell seems to exhibit greater affinities to recent pteropodous molluscs.

TE'NTERDEN, a municipal borough and market-town in the Weald of Kent, 18 miles south-south-east of Maidstone. The church, which contains portions of Early English, is surmounted by a massive and lofty perpendicular tower. Tradition asserts, that a quantity of stones, which had been got together for the purpose of strengthening the sea-wall of the Goodwin Sands, were employed in the building of this tower, and that when the next storm came, the district of Goodwin Sands, which had formerly belonged to the mainland, was submerged. Thus arose the popular saying, that 'Tenterden steeple was the cause of the Goodwin Sands. Pop. (1871) 3669; (1881) 3620.

TENTERDEN, CHARLES ABBOTT, LORD, a distinguished English lawyer, was born at Canterbury, on the 7th October 1762. He was the son of a hairdresser. Being admitted on the foundation of the King's School connected with the cathedral, he distinguished himself by perseverance and extreme accuracy. A small exhibition in the gift of the chapter enabled him to proceed to Oxford, where, in 1781, he was elected scholar of Corpus Christi College; and a few years later, he obtained what were then the chief distinctions at the university, the Chancellor's two gold medals, one being for English, the other for Latin composition. In due time, he became a Fellow of his college. After being a student of the Inner Temple, in 1795, he was called to the bar. He joined the Oxford circuit; and in spite of a husky voice, a leaden and unmeaning countenance, and painfully timid manners, his great activity of mind, good taste, scholarship, scientific and legal knowledge, were soon appreciated, so that he rapidly acquired a large business. He published, in 1802, his treatise *On Merchant Ships and Seamen*, in all respects the best written book which had till then appeared on one department of English law. It had the effect of increasing his employment in the more lucrative mercantile causes; and in 1807, it appears from his income-tax return that his fees amounted to upwards of £8000. In 1816, he accepted a puisne judgeship in the Court of Common Pleas; and in 1818 he was knighted, and chosen to succeed Lord Ellenborough as Chief-justice of the King's Bench. As a judge, his most marked characteristic was his evident impartiality and freedom from bias. The comparative leisure he enjoyed on the bench he spent in reading the classics and in the study of botany. He was, in 1827, raised to the peerage. In the House of Lords he was the most influential speaker against the Catholic Relief Bill; and in his last speech, he made a vow that if the Reform Bill, that 'appalling bill,' passed, he would never again take his seat as a peer. The success of the measure, it is believed, affected his health. He was seized with a violent attack of inflammation in November 1832, when presiding at the trial of the mayor of Bristol for misconduct during the riots, and he died there on the 4th of that month.

TENUIRO'STRÉS, a tribe or sub-order of birds, of the order *Insessores*, characterized by a lengthened slender bill, which is sometimes straight, sometimes curved. Some of them feed on insects, some chiefly on the honey of flowers. To this tribe belong the Creepers (*Certhiadæ*), Sun-birds (*Cinnyridæ*), Humming-birds (*Trochilidæ*), and Hoopoes (*Upupidæ*).

TENURE OF LAND, in England, was an accompaniment or immediate consequence of the Feudal System (q. v.) established during the middle ages throughout the greater part of Europe. Feuds were introduced by the barbarous tribes who poured themselves into the Roman Empire during the 4th, 5th, and 6th centuries. The chief feature of feuds was, that the lands of the conquered country were parceled out to the leaders, on the condition of bearing arms whenever the sovereign required them. The relation thus created between sovereign and vassal was called a feud. The grantee held his lands at first for life only, but gradually it was developed into a hereditary character, and also into one which admitted of subinfeudation, i. e., the parcelling out of the feudal land among vassals of the head vassal, who was the lord of his own vassals. This kind of relation between lord and vassal gradually was extended to all kinds of land, for the owners of allodial land voluntarily surrendered their land to some lord, so as to have the same advantages. The vassal did homage to the lord, and took the oath of fealty. Besides these characteristics, the holding came to be attended with the following incidents. 1. An aid, which was a payment granted to help the lord in his necessities. 2. A relief was a tribute paid by a new tenant on succeeding to his predecessor. 3. A fine was paid by a tenant to the lord on alienating the lands to a purchaser. 4. An escheat or forfeiture was the reverting of the estate to the lord when there was a failure of heirs or some violation of duty on the part of the vassal.

The feudal system was extended to England by the Norman barons soon after the Conquest, with the concurrence of William I., much to the dislike of the Saxons, whose grievances grew until they found vent in Magna Charta, which was in fact an attempt to restore their earlier constitution. The chief fiction, however, of a relation between the crown and the holders of land was not got rid of. The crown was nominally the lord paramount, and there were intermediate lords called mesne lords, of whom the tenants held. Gradually, the kinds of tenure were classed under free and base services—the former being those which a freeman might perform, as serving in war, or paying a sum of money; the latter, such as a peasant might perform, such as ploughing the lord's land, &c. These were afterwards further distinguished according to the certainty or uncertainty of the extended services to be performed. Ultimately, the tenures were classed as three. 1. *Knight-service*, or chivalry, i. e., holding on condition of serving in the war, and taking the oath of fealty. This was accompanied by the incidents of descent, wardship (or guardianship of the knight's heir by the lord), marriage (i. e., the lord's right to give the knight's infant in marriage), aids, reliefs, primer seisin (i. e., one year's profits from an heir on his succession), fine, escheat, and forfeiture. These incidents gradually grew irksome. JAMES I. proposed to commute knight-service into an annual fee-farm rent; but this not being done, the statute of 12 Ch. II. c. 24 swept the whole away, and converted it into free socage. 2. *Free socage* was a tenure by some certain and determinate service, as by paying a small fixed rent, or ploughing the lord's lands for a fixed number of days. The incidents were rather less burdensome than those of knight-service, being descent, wardship, marriage, and reliefs, primer seisin, fines, escheat, and forfeiture. These incidents were all abolished by the above statute of 12 Ch. II. c. 24, and the tenure of free socage is now generally known as freehold. 3. *Villenage service*, or Copyhold Tenure (q. v.), which still exists nearly in its original state. The result is, that in England at the present day the two tenures are freehold and copyhold.

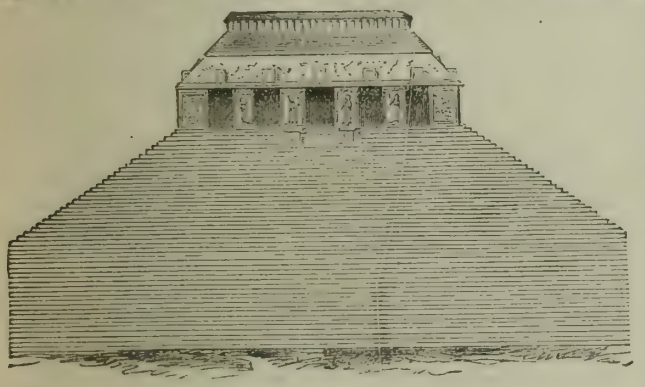
The leading characteristic of freehold is, that practically the feudal relation between the crown and the holder is cut off, and the holder is entirely his own lord and master, can sell the estate, devise it by will, give it away, and do what he likes with it free from any interference or payment to the crown. As to copyhold, the feudal relation is kept up to a certain extent between the lord and the copyhold tenants, who must in form pay rents more or less nominal, and fines and Heriots (q. v.) to the lord on alienating the lands or succeeding thereto. Yet, practically, the copyholder

does not materially differ from a freeholder except that he is liable to these petty and harassing acknowledgments towards a stranger; and by recent statutes, he can compel the lord of the manor to commute these fines and incidents, and convert the tenure into freehold.

In Ireland, the tenure of land is almost identical with that in England; but see TENANT RIGHT.

As to Scotland, there is a marked difference between the tenure of lands there and the tenure in England. At the present day, the feudal system prevails to a great extent, resembling in many respects the English copyhold tenure. Every piece of land there has generally its lord or superior and its vassal, that is to say, the vassal has the *dominium utile*, or actual enjoyment, while the superior has a kind of superior interest, or *dominium directum*, which consists in his drawing a rent called a feu-duty, which the vassal is bound to pay, or to forfeit the land. On each alienation or death of the vassal, there must be certain forms superadded, implying a consent or recognition by the superior, and certain casualties or additional payments must be made on such occasions. Recent statutes have tended to extinguish several of these superfluous forms, and make the vassal more independent. But a great many remain unaltered. And not only is there this feudal relation between the crown and its vassals, but these may subdivide the property and create intermediate estates without limit, each vassal being in turn the superior to his subvassal; and this endless chain of relationships complicates the conveyancing still more. See CONVEYANCING; FEU.

TEOCA'LLI (House of God), the name given to the temples of the aboriginees of Mexico, of which many still remain in a more or less perfect state. They were built in the form of four-sided pyramids, and consisted for the most part of two, three, or more stories or terraces, with the temple, properly so-called, placed on a platform on the summit. The largest and most celebrated is the pyramid of Cholula, measuring 1440 feet each way, and 177 in height; it is much defaced, and the temple on its summit has



Teocalli at Palenque.

been removed. The teocallis in Yucatan are in far better preservation; they are not generally built in terraces, but rise at an angle of 45° to the level of the platform, with an unbroken series of steps from base to summit. The temples on their summit are sometimes ornamented with bas-reliefs in stucco and hieroglyphic tablets, and the roof is formed by courses of stone approaching each other, and furnished with projections like dormer windows. The preceding woodcut gives the elevation of a large teocalli of this kind at Palenque, on a scale of 50 feet to the inch. Not unlike the tocallis are the palaces of the Aztec kings or chiefs, which differ from them in having the pyramids smaller, less prominent, and oblong in plan, while the building, larger and more elaborate, consists for the most part of a stone basement, with square doorways, but without windows, surmounted by a structure which appears to be directly copied from wood-work. On some of these façades, we have also rude pillars and grotesque carvings, and there are often a number of chambers in the interior. A palace and temple are sometimes found attached together; and in a few cases, the most remarkable of which is the Casa de las Monjas, at Uxmal, the buildings are arranged round a courtyard. See MEXICO.

TEPI'C, a town of Mexico, in the state of Jalisco, on a height 400 miles north-west of the city of Mexico. T. is the residence, during the rainy season, of many of the inhabitants of the port of San Blas, about 25 miles distant. Pop. 10,000.

TERA'MO (anc. *Interamna*), a town of southern Italy, in the province of the same name, at the junction of the Tordina and Vezzola, 28 miles north-east of Aquila. It is well built, with long and rather wide streets, has a cathedral, a public library, a foundling-hospital, and a botanic garden, carries on an active trade in corn, wine, and olives, and has a pop. of (1881) 8634.

Ancient *Interamna* (of which the name T. is an Italianized form) was a city of Picenum, in the territory of the Prætutii. In the middle ages, it also bore the name of Abrutium or Aprutium (supposed to be a corruption of Prætutii), whence the modern name of the district, Abruzzo. Vestiges of the ancient city—the amphitheater, temples, baths, aqueducts, &c.—are traceable, and many statues, altars, and inscriptions have also been discovered. In the plain below T. took place, July 27, 1460, between the army of John, Duke of Anjou, and the Milanese allies of Ferdinand I. of Aragon, one of the most sanguinary battles ever fought in Italy. After the contest at Castelfidardo (1860), T. was the first Neapolitan city that opened its gates and gave joyful welcome to King Victor Emmanuel.—Pop. of province, (1881) 254,986.

TE'RAPHIM (Heb. plur.) a word of uncertain derivation (connected by some with Serapis), denoting certain images, idols, or household gods occurring in the Old Testament, which were consulted as oracles, and probably even worshiped to a certain extent. The gods which Rachel stole are called Teraphim, and Saul was reproached by Samuel for stubbornness which is like Teraphim; his daughter placed a Teraph into David's bed to conceal his flight, &c. There is no proof that this veneration for Teraphim was not held perfectly compatible with the worship of Jehovah, spite of some reformatory attempts to sweep them away. Many and curious have been the explanations given of the nature of the Teraphim by different scholars in and out of the synagogue. A vague but generally prevailing notion is that of their having been a kind of astrological automata, which somehow or other could be made to move, and to utter certain sounds. All that is certain, however, is only the fact, that the real meaning and character of this strange idol had been forgotten already at a very early period.

TERATO'LOGY (Gr. *terata*, wonders, or monsters) is a term used in Physiology as synonymous with 'The History of Monstrosities or Anomalous Formations.' See MONSTROSITY.

TE'RBIUM, a very rare metal, whose oxide, *Terbia*, is found in association with the rare earth Yttria, the oxide of Yttrium (q. v.).

TERBURGH, GERHARD, a Dutch painter, belonging to an old and respectable family of Zwoll, was born in 1608, studied first under his father, who was also an artist of note, and afterwards visited Germany, Italy, Spain, England, and France. On his return to his native country, he settled at Deventer, of which town he became burgomaster, and died in 1681. The elegant ostentatious life of his time, with its superfine courtly manners, and splendid costume, found in T. an admirable painter. The central figure in many of his pictures is a young lady with fair hair, and dressed in white satin. His most famous piece, however, is a picture containing portraits of the 69 plenipotentiaries who drew up the Treary of Westphalia. In Dr. Waagen's opinion, T. is the real founder of the art of painting conversation-pieces, and at the same time the most eminent master in this style. 'In delicacy of execution, he is inferior to none; and in a certain tender fusing of the colors, he excels all others; but none can be compared with him in the enchanting harmony and silvery tone, and the observance of the aërial perspective. His figures, which are well drawn, have an uncommon ease of refinement, and are frequently very graceful.' T.'s works are to be found in various English collections, particularly those of Sir Robert Peel, the Duke of Sutherland, Lord Ashburton, Mr. Hope, the Marquis of Bute, and Her Majesty; as also in the galleries of Dresden, Munich, Vienna, the Louvre, Amsterdam, and Berlin.

TERCE (Lat. *tertia*—i. e., *hora*, the third hour), one of the 'Lesser Hours' of the Roman Breviary, so called from the time of the day for which it is fixed. See CANONICAL HOURS.

TERCE, in the Law of Scotland, is the interest or estate which a widow has in the land of her deceased husband at common law. This amounts to a liferent of one-third of such estates. In estimating the estate of the husband, all real burdens must be first deducted, and certain other things—as the mansion-house, if there is only one, superiorities, and patronage, leases, and feu-duties. The mode by which a widow completes her title to the terce is by a process called *Kenning to the Terce* (q. v.), the object of which is to separate her portion from the rest, which goes to the heir, so that each may possess independently his and her portion respectively. She is then in the position of an ordinary proprietor for life. Though terce is a legal right, yet this right of the widow may be modified by an antenuptial contract, under which she is otherwise provided for.—In England and Ireland, a widow has a similar right, called Dower (q. v.).

TERCEI'RA, one of the Azores Islands (q. v.), and the second in size of that group, forms one of the central cluster, and lies eastward from San Jorge. Area, 220 sq. m.; pop. between 40,000 and 50,000. Steep rocks of lava almost everywhere line the coast; the island is accessible only at few places, and these are defended against invasion by fortifications. The soil is fertile; the plateaux of the mountains afford excellent pastures, and cattle-breeding is

an important branch of industry; the principal articles of export are wine, timber, and orchil. Chief town of the island, Angra, the capital (pop. 18,000), in the fort of which reside the governor and the bishop of the Azores.

TEREBINTA'CEÆ. See ANACARDIACEÆ.

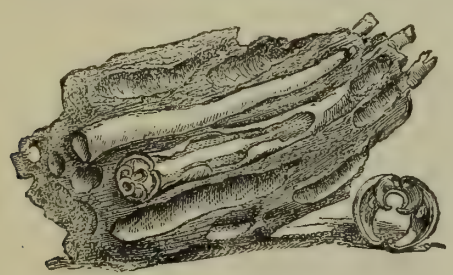
TEREBRA'NTIA, a section of the insect order *Hymenoptera*, distinguished by the females having an ovipositor. To this section belong Saw-flies (*Tenthredinidæ*), Ichneumons, Gall-insects, &c.

TEREBRA'TULA, a genus of deep-sea brachiopodous molluscs. The animal is attached to the shell by a pedicle, and the brachial disc is three-lobed, the center lobe being elongated and

Terebratula:
a, valve with the spiral arms; *b*, valve with arms removed.

spirally convoluted. The shell is smooth, with a truncated perforated beak, the foramen being circular. The shelly loop is very short and simple. The shell of this genus, and some of its allies, is covered with minute quincuncial perforations, sometimes visible to the naked eye, but usually requiring a lens of a low power to distinguish them. The generic title is now restricted to shells with a short internal loop. The species with long loops are grouped together under the name *Waldheimia*. Of the restricted genus, there is only a single living species (*T. vitrea*); but the fossil species are more than a hundred in number, and are found in all periods of the earth's history, from the Devonian age upwards.

TERE'DO, a genus of lamellibranchiate molluscs of the family *Pholadidæ;* very much elongated, and worm-shaped; the mouth very delicate, open in front and at its lower part, for the passage of the short foot; the shell rather thick, equivalve, destitute of hinge, gaping at both ends. The species are rather numerous,



Common Shipworm (*Teredo navalis*).

and are generally known by the name of SHIPWORM or PILEWORM, because they perforate and live in timber. Their perforations are made in the direction of the grain of the timber, except when a knot is met with, or the shell of another *Teredo*, when they accommodate themselves to circumstances by bending. The cavity is lined with a calcareous incrustation.

The aperture by which the T. enters is small, and it grows within the cavity which it makes. Two small valves form the true bivalve shell; the calcareous tube encloses the worm-shaped body of the animal. Its growth is very rapid, and its ravages are often terrible. A piece of deal has been found riddled by shipworms after forty days' immersion. Ships, piles, and all submarine woodwork are destroyed by it. Copper-sheathing is employed to protect ships from the ship-worm, or the timber is driven full of short, broad-headed nails, the rusting of which forms a coating which it does not penetrate. The dykes of Holland have been threatened with destruction by its ravages. The COMMON SHIPWORM (*T. navalis*) is said to have been introduced into Europe from warmer climates. It is now, however, extremely abundant in European seas. In the East Indies, a very large species (*T. gigantea*) is found, generally in shallow water among mangrove trees; it is sometimes more than five feet in length, and at the thickest part three inches in diameter.

TERE'K, one of the most considerable streams of the Caucasus, rises near the lofty Mount Kasbec (about 17,000 feet high), flows north-west through the defiles of the mountains, crossing the district of the Kabarda, and reaches the border of the government of Stavropol, where it curves eastward, forming the south boundary of that government, until, reaching Kisliar, it divides into numerous branches, which form a delta 70 miles broad, and 50 miles long from apex to base, and falls into the Caspian Sea. It is not navigable. Total length estimated at from 300 to 390 miles.

TERE'NTIUS A'FER, PUBLIUS, the comic poet, was born at Carthage, 195 B.C. By birth or purchase, he became the slave of the Roman senator P. Terentius Lucanus, who, out of regard to his handsome person and unusual talents, educated him highly, and finally manumitted him. On his manumission, he assumed, of course, his patron's *nomen*, Terentius. His first play was the *Andria*, written in his 27th year, but not acted till 166 B.C. Its success was immediate, and introduced its author to the most refined society of Rome, where his engaging address and accomplishments made him a particular favorite. His chief patrons were Lælius and the younger Scipio, after living with whom in great intimacy for some years in Rome, he went to Greece, where he translated 108 of Menander's comedies. He never returned; and the accounts of how he came by his death are conflicting. He is supposed to have died in his 36th or 37th year, leaving one daughter. Six comedies are extant under the name of T., which are perhaps all he produced—viz., *Andria*, *Hecyra*, *Heauton-timoroumenos*, *Eunuchus*, *Phormio*, and *Adelphi*. In conjunction with Plautus, T., on the revival of letters, was studied as the model by the most accomplished play-writers. His language is pure almost to being immaculate, and though inferior to Plautus in comic power, he is more than his match in consistency of plot and character, in tenderness, in wit, and in metrical skill. His plays have an educational value, as dividing, with the works of Cicero and Cæsar, the honor of being written in the purest Latin. They have been translated into most of the European languages. The best editions of his works are those of Bentley (Cambridge, 1726), and of Parry (1857).

TERESA, ST., one of the most remarkable of the female saints of the modern Roman calendar, and the most admired of the modern mystic writers of that communion, born at Avila, in Old Castile, March 28, 1515, was the daughter of Alfonso, of the noble House of Sanchez de Ceyeda. Even as a child, T. was remarkable for piety of a most enthusiastic kind; and when she was but seven years old, she and her little brother, Rodrigo, fled from her father's house, with the design of offering themselves for the crown of martyrdom among the Moors, but were overtaken, and restored to their parents. Her mother died while she was still young, and she was educated in a convent at Avila, from which, however, she was compelled by illness to return home when she was in her 16th year. During her illness, she resolved, notwithstanding the very earnest opposition of her father, to become a nun, and having in her 18th year entered a convent of the Carmelite order in her native city, she made her solemn vow on the 3d November 1534. In this convent she continued to reside for nearly thirty years, but it was not till about the year 1539, that her constitution became strong enough to permit her to follow, even in an imperfect way, the observances of conventual life. Her own account of her mental and spiritual condition during this period, which extended to the year 1555, is extremely interesting, and, like the confession of St. Augustine and other saints, has furnished endless materials to the spiritualists of more recent times. The change of heart and of purpose came in 1555—1556, and was as complete and decisive as her former condition had been purposeless or fluctuating. After a time, her religious exercises reached a most extraordinary degree of asceticism. Her prayers were almost continual, and she was reported to be favored with visions, ecstasies, and other supernatural visitations, of which many curious details are related by her biographers, and in her own letters and papers. The fame of her sanctity spread not only throughout Spain, but into almost every part of the church. By some, the reality of the reported supernatural favors which were ascribed to her was called into question; and there were even some who threatened to invoke the rigorous investigation of the Holy Office; but the popular voice was freely accorded to her, and the authority of St. Francis Borgia, St. Peter of Alcantara, and other high names, eventually disarmed the opposition.

The most notable and permanent fruit of the enthusiastic spirituality of T. is the reform of the Carmelite order, of which she became the instrument. She commenced this work in concert with a few zealous members of her own sisterhood in the convent at Avila, where she had resided from the date of her profession; but after a time, she obtained permission from the Holy See, under the direction of Peter of Alcantara, to remove with her little community to St. Joseph's, a small and very humble convent in the same city, where she established in its full rigor the ancient Carmelite rule, as approved by Innocent IV. in 1247, with some additional observances introduced by T. herself. This new convent was established in 1562, and in the end of that year, or the beginning of 1563, T. took up her abode therein; and in 1565, she obtained from the pope, Pius IV., a formal approval for the rule as modified by her. For two years, T. lived in great privacy and

quiet in her convent of St. Joseph; but in 1567, the general of the Carmelite order, F. Rubeo, was so struck during his visitation of the convents at Avila, with the condition of that over which T. presided, that he urged upon her the duty of extending throughout the order the reforms thus successfully initiated. T. entered upon the work with great energy, and although she met with much opposition, nevertheless succeeding in carrying out her reforms. In 1579, the Carmelites of the stricter observance established by T. were released from the jurisdiction of the old superiors, and united into a distinct association, with a separate head and a distinct organization, which was approved in 1580 by Pope Gregory XIII.

Under this new constitution, the association flourished and extended; and within the lifetime of T., no fewer than 17 convents of women and 16 of men accepted the reforms which she had originated. T. died at Alba, October 4, 1582, in her 68th year. She was canonized by Gregory XV. in 1621, her feast being fixed on the 15th October. She left a number of works, which have at all times maintained a high reputation among the spiritualists of her own church, and whose merits, in many respects, are acknowledged by non-Catholic writers. They consist of ascetical and mystical treatises, instructions in the conventual life, meditations, &c., besides a large number of letters, which possess remarkable literary merit, quite independent of their doctrinal character. Her works in the original Spanish fill two folio volumes, and they have been in the whole or in part translated into almost every European language. Her life occupies nearly an entire volume of the new continuation of the *Acta Sanctorum;* and several more popular biographies have been written in Spanish, French, Italian, German—the best known English one being that by the Rev. Canon Dalton. See *Leben der heil. Theresia*, von Dr. Fr. Pösl (Regensburg, 1847).

TERLI'ZZI, a flourishing, well-built town of Italy, in the province of Bari, 20 miles south-east of Barletta, and 8 miles from the Adriatic. It contains a cathedral, a parish church, and three convents. The almond tree is extensively cultivated in the vicinity. Pop. (1881) 20,442.

TERM, in Legal phrase, has several meanings, but that best known is when it denotes certain days of the year for calculating rent between landlord and tenant, and which have been adopted by immemorial usage, owing to the convenience of thus terminating the contract between the parties. In England and Ireland, the year is for this purpose divided into four quarters or terms. These are—Lady-day, March 25; Midsummer-day, June 24; Michaelmas-day, September 25; and Christmas-day, December 25. In Scotland, the terms as between landlord and tenant are divided into legal and conventional terms. There are two terms recognized by common law—viz., Whitsunday, May 15; and Martinmas, November 11; while other two conventional terms subdivide these—viz., Candlemas, February 2; and Lammas, August 1.—There is also a subdivision of the year into Law-terms (q. v.), adopted and sanctioned by statute for the purpose of the sittings of the law-courts. These are Hilary, Easter, Trinity, and Michaelmas terms.—There is a third and technical meaning of the word 'term,' when it means an estate for years in land.

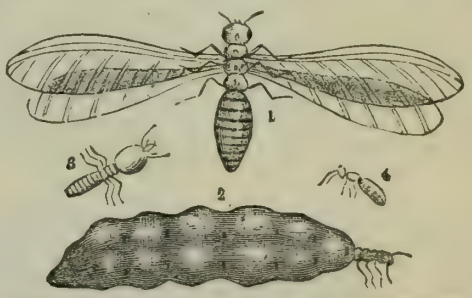
TE'RMINI (anc. *Thermæ Himæræenses*), a seaport town on the north coast of Sicily, 21 miles east-south-east of Palermo, at the mouth of the river Termini. It is built partly on a plateau (the summit of which is crowned by a castle—now a prison—of mediæval construction), and partly on the slope and in the hollow beneath. T., with its noble background of towering hills, and its magnificent view of the Mediterranean, well deserves the title of *La Splendidissima*, bestowed on it by the Emperor Frederick II. Many of the inhabitants are engaged in fishing for tunny and anchovies. Pop. about 20,000.

The ancient *Thermæ* (of which T. is an Italian corruption) was founded 408 B.C., after the destruction of the Greek city of Himæra, and whence its name Himærenses. Whether it owed its origin to the Carthaginians themselves, or to the surviving citizens of Himæra, is doubtful; but it soon passed under the authority of the former, who here defeated the Romans with heavy loss (260 B.C.) during the first Punic war. After Sicily became a Roman province, Thermæ was treated with peculiar consideration by its new masters, and became a flourishing place. Relics of the ancient city, as the baths (which are still used), fragments of a theater, and aqueduct, are still visible; and numerous inscriptions, statues, &c., are preserved in public and private collections.—See B. Romano's *Antichità Termitane* (Palermo, 1838).

TE'RMINUS, a Roman divinity, supposed to preside over public and private boundaries. Originally, he appears to have been the same as Jupiter himself, but gradually he was recognized as a separate and distinct god. Hardly any religious conception is more thoroughly characteristic of the Romans, that land-loving, law-reverencing people, than the conception of T., whose worship was practised down to a late period.

TE'RMITE, or WHITE ANT (*Termites*), a genus of insects of the order *Neuroptera*, and of the family *Termitidæ*, or *Termitinæ*. They live in great communities, chiefly in tropical countries, and are almost omnivorous, in the larva, and pupa, as well as in the perfect state. In their communities, there are five classes —males, females, workers, neuters, and soldiers. The workers, neuters, and soldiers seem all to be imperfectly developed females. The males and perfect females have four wings, which are long and nearly equal, and which are often suddenly cast off before the termination of their life; but the greater part of the community consists of workers, which are wingless. The 'soldiers' are larger than the neuters, and have very large mandibles, which they are always ready to use upon any assault. The antennæ of the genus *Termes* are long and thread-shaped, with about 20 joints; the eyes are small and prominent, and there are three *ocelli;* the abdomen has a pair of minute caudal appendages.

Most of the white ants make their nests on the ground, but some of them among branches of trees, decayed or dry wood forming a principal article of their food. The species which make their nests on the ground make them conical, or turret-shaped, often 12 feet, and sometimes even 30 feet high, in groups, like a little village. The soil where the white ants have labored is particularly good, and the South Africans take advantage of its excellent quality. The nest is divided internally into numerous chambers and galleries; there are generally two or three roofs within the dome-shaped interior, and the thick walls are perforated by passages leading to the nurseries and magazines of food. If a breach is made in the building, the soldiers appear, ready for defence. White ants are very useful in consuming every kind of decaying animal or vegetable matter. They even eat grass, and



1, Perfect male Termite: 2, Female, distended with eggs; 3, Soldier; 4, Worker.

the snapping of multitudinous mandibles has been likened to the sound of a gentle wind among trees. They sometimes attack the wood-work of houses, and soon reduce the thickest timbers to a mere shell. Extraordinary and incredible stories are told of their attacking and devouring large animals, but it seems probable that they do so only when the animals are helpless from age or sickness. They come in vast hosts to any place where food is to be found, and are not easily driven off; multitudes pressing on, although previous multitudes have been destroyed. They gather great stores of corn into their nests, of which the natives of Africa often avail themselves. They are themselves also used as food in Africa, and are said to be delicate and pleasant. The abdomen of the pregnant female T. becomes dilated to an extraordinary degree, so as to exceed the rest of her body 1500 to 2000 times, and she is then about 1000 times heavier than the male insect. Her fecundity is prodigious; she is supposed to lay more than 31,000,000 of eggs in a year.

The Termites which live in trees construct nests of great size, like sugar-casks, of particles of gnawed wood, cemented by a kind of gluten, and so strongly attached to the branches as not to be shaken down even by violent storms. These species sometimes take up their abode in the roofs of houses, where they are very destructive to the wood-work.

Termes mordax and *T. atrox* are among the African ground-building species. *T. lucifugus* is found in the south of Europe, and has proved very destructive in the navy-yard of Rochefort, and elsewhere in the south of France. Sulphurous gases and chlorine are forced into its galleries, without completely effecting its extirpation. *T. flavicollis* is very injurious to olive trees in Spain. *T. frontalis* extends as far north in the United States as Massachusetts, and does mischief in vineries, not only attacking dead wood, but the roots of living vines. No true species of *Termes* is found in Britain, but some of the *Termitidæ* are British insects. One of them is *Psocus pulsatorius*, one of the insects which emit a sound like the ticking of a watch in houses. The species of the genus *Psocus* are very small, active insects, living beneath the bark of trees, in wood, straw, &c. Some of them are often found among books and in collections of natural history.

In books of travels, the termites are often called ants, their habits being similar, although they belong to a different order of insects.

TERN (*Sterna*), a genus of birds of the Gull family (*Laridæ*), by some made the type of a distinct family (*Sternidæ*); having the bill as long as the head, or longer, nearly straight, compressed, slender, tapering; the wings long and pointed; the tail long and forked. The plumage is very full. From their forked tail, manner of flight, and small size, the terns are often called sea-swallows. They are incessantly on the wing, skimming the surface of the water, and catching small fishes and other small animals from it. The species are numerous, and are found in almost all parts of the world. Some of them are of very wide geographic distribution. Many are birds of passage. Thus, all which occur on the British coasts, and in other northern parts of the world, are mere summer visitants. The COMMON T. (*S. hirundo*) is abundant on the more southern shores of Britain, but rarer in the north. It is found also on the coasts of Europe, Asia, and Africa, from the Arctic Circle to the farthest south; but there is some doubt if its range extends to America, where a very similar species, WILSON'S T. (*S. Wilsoni*), was long mistaken for it.

TERNA'TE. See MOLUCCAS.

TE'RNI (anc. *Interamna*), a town of Central Italy, on the right bank of the Nera (anc. *Nar*), a little below its confluence with the Velino, 49 miles north-north-east of Rome. It is encircled by a wall, with towers and five gates, is well-built, gives name to an archbishopric, and possesses a cathedral, several fine palaces and churches, a hospital, theater, and various monuments of antiquity, as the ruins of an amphitheater, temples, and baths—none of which, however, are of much importance. T. manufactures silk and woollen fabrics. Pop. about 14,000. About two miles from the town is the famous cataract of Velino, 500 feet high, celebrated by Byron in his *Childe Harold*.

Ancient *Interamna*, according to classic tradition, was founded only 80 years after Rome, but we have no knowledge of its history until it ceased to be an Umbrian, and became a Roman city. About the time of Marius and Sulla, it was (according to Florus) one of the *florentissima Italiæ municipia*, but at no period did it occupy a very prominent position. Its chief claim to notice arises from its being regarded (by some) as the birthplace of the historian Tacitus, and of his descendant, the emperor of the same name.

TERNSTRŒMIA'CEÆ, a natural order of exogenous plants, allied to *Guttiferæ*, and consisting of trees and shrubs, natives of warm and temperate countries. About 150 species are known. They are most abundant in South America; a few are found in North America; some in India, China, and other parts of the East; only one African species is known; and Europe produces none. The leaves are alternate, leathery, in many species evergreen, generally undivided, sometimes dotted. The flowers are on axillary or terminal stalks, generally white, sometimes pink or red; with 5—7 concave, leathery, deciduous sepals, and 5—9 petals, which are often combined at the base; many hypogynous stamens, which are either free or variously combined; 2—7 filiform styles, more or less combined; the fruit a 2—7-celled capsule, either opening by valves, or leathery and indehiscent, the seeds large, few, and attached to the axis, the cotyledons very large, and often containing much oil. This order is very important as containing the Tea-shrubs. It is also interesting because of the great beauty both of the foliage and flowers of many of the species, of which the genus *Camellia* affords the best-known examples. See TEA, CAMELLIA, and GORDONIA.

TERPSI'CHORÉ (Gr., delighting in the dance), one of the nine Muses (q. v), presided over choral song and dancing.

Statue of Terpsichore.

TERRACI'NA (anc. *Tarracina*), a town of Central Italy, in what was formerly the Papal States, is situated on the coast at the south-east extremity of the Pontine Marshes, near the mouths of the Ufente and Amaseno. It is the seat of a bishop, possesses a cathedral (built on the ruins of a heathen temple), a square with a handsome fountain, a palace of Pius VI., and on the summit of a precipice overlooking the town, the ruins of a palace of Theodoric, king of the Goths. The harbor, a naval station of the Romans, is now filled up. Pop. 7600.

Tarracina was originally a Volscian town, and was called by the Volscians *Anxur*, a name which is often applied to it by the Latin poets. It fell into the hands of the Romans 400 B.C., became the seat of a Roman colony 329 B.C., and as long as the Republic and Empire lasted, was a flourishing and important city. So closely do the mountains here approach the sea, that there was scarcely room for the celebrated 'Appian Way;' hence the importance of T. as a military position. Numerous ruins of the ancient town are extant.

TERRA-CO'TTA, an Italian term signifying *baked-clay*. It is applied chiefly, if not altogether, to manufactures of brick-earth used for ornamental purposes, especially those used architecturally. Formerly, it was not uncommon in Britain, particularly about the beginning of the 18th c.; but after the reign of Queen Anne, it was discontinued, and was scarcely ever used until within the last ten years. A complete revival has now taken place, and this material has been applied with admirable effect in some of the buildings lately erected, especially the South Kensington Museum, and the Charing Cross Railway Station Hotel.

TE'RRA DEL FUE'GO, more correctly, Tierra del Fuego (q. v.).

TE'RRA DI LAVO'RO (*Campania Felix*), now CASERTA, a maritime province of Southern Italy, bounded on the N.-W. by what was formerly the Papal States. Area, 2326 square miles; pop. (1881) 714,487. This is the famous *Campania Felix* of the ancients. Pliny extols its beauty and its fine situation. Florus calls it the finest country in the world. In ancient times, it was inhabited by the Ausonii, the Osci, and later by the Campani. The finest part of Campania has been separated from it, and is that fertile tract of country which surrounds the Gulf of Naples like an amphitheater; another part has been added to the province of Molise. T. di L. is watered by two rivers, the Liris or Garigliano and the Volturno. Towards the east, it is broken up by the Apennines, and its beautiful ranges of hills are clothed with vine and olive yards, and studded with country-seats. It produces corn, strong wines, oil, fruits, and silk. Its seaport towns are populous and busy, although here and there the sea-board is interrupted by marshes. The climate is very mild in winter, and extremely hot in summer.

TE'RRA DI SIE'NNA. See BURNT SIENNA.

TERRA-FI'RMA, a term frequently employed to denote continental land as distinguished from islands. But it was at one time more specially applied—1st, to all the mainland of Italy which acknowledged the supremacy of Venice—viz., to the duchy of Venice, Venetian Lombardy, the March of Treviso, the duchy of Friuli and Istria; 2d, to that extensive tract of South America, bounded by the Pacific Ocean, Peru, the silvas of the Amazon, the Atlantic Ocean, and the Isthmus of Panama, which mostly belonged to the Spaniards during the last century. In a still more restricted sense, the term was applied by the Spaniards to the Isthmus of Panama itself. Colloquially, the phrase *terra-firma* is applied (but erroneously) to land as distinguished from water.

TERRA JAPO'NICA. See CATECHU.

TERRANO'VA, a seaport town on the south coast of Sicily, province of Caltanisetta, on the right bank of the Omonimo, 18 miles E. from Alicata. Pop. (1881) 17,173. There is no regular port, but the town carries on a good trade in fruit, corn, pulse, sulphur, soda, and above all, in cotton, large quantities of which are grown in the vicinity. A kind of coarse cloth is manufactured for home consumption. T. is believed to occupy the site of the ancient Gela (q. v.). The town now standing was built by Frederick II. in the 12th century. In its neighborhood is the village of Mazarino, from which the famous cardinal took his name.

TE'RRAPIN, the popular name of many species of fresh-water tortoises, of the family *Emydæ* (see EMYS), natives of tropical and the warmer temporate countries. The neck can be wholly retracted within the shell; the head is flat, and the jaws prolonged into a beak. They feed partly on vegetable food, but also devour fish, reptiles, and other aquatic animals. They swim very well, and even on land move with much greater swiftness than land-tortoises. Their flesh is generally much esteemed.—Several species are natives of North America.

TERRE HAUTE, a city of Indiana, U. S., on the east bank of the river Wabash, 78 miles west-south-west of Indianapolis; a handsome town, regularly built, on an elevated plateau, in a rich agricultural country, with three railways, the Wabash and Erie Canal, machine-shops and manufactories. It has 3 banks, 4 public-school edifices, Roman Catholic convent and schools, free college, 13 churches, 3 daily and 3 weekly papers, 2 public libraries, and abundant supplies of bituminous coal. Pop. (1870) 16,103; (1880) 26,040.

TERRE-PLEIN, in Fortification, is the flat surface of the rampart, on the front portion of which the parapet and banquette are formed, and of which the rear slopes down to the general level of the enclosure.

TERRE'STRIAL MAGNETISM. In the article MAGNETISM, it is shown that the earth itself is to be considered as a great magnet; and in the present article it is proposed to exhibit the chief results of observation on the earth's magnetism as seen in its action on artificial magnets. That action is simply *directive;* that is, it determines the way in which the magnet shall point, but has no tendency to translate or move it bodily. Terrestrial magnetism

acts differently at different places; what are called the *magnetic elements* of a place, are the direction of the needle in regard to the points of the horizon (*variation* or *declination*), its direction in regard to the verticle (*inclination* or *dip*), and the force that keeps it in these positions (*intensity*). For the first two elements see DECLINATION-NEEDLE and DIPPING-NEEDLE. The element of intensity is more difficult to determine. The relative horizontal intensity is measured by the number of oscillations that a needle, of unit size and strength, when disturbed makes in a given time, the intensities of two places being as the squares of the oscillations. The total intensity is got by dividing the horizontal intensity by the cosine of the angle of dip. Gauss has succeeded in reducing this measurement from a relative to an absolute standard.

Magnetic Charts.—The magnetic elements have been ascertained with great care at different portions of the earth's surface. The knowledge thus obtained has been embodied in magnetic charts, in which the points at which the declination is the same are joined by lines, and similarly those where the dip and intensity are alike. The lines of equal declination are called isogonic lines; those of equal dip, isoclinic; and those of equal intensity, isodynamic lines. As the magnetism of the earth is subject to a slow secular variation, such charts are only true for the time of observation. The chart, fig. 1, was drawn up by Colonel Sabine for the year 1840, and gives an approximate view of the lines of equal declination for that year. The change since 1840 has been small, so that an isogonic chart for the present time would differ but slightly from it. The chart sufficiently explains itself. Attention may, however, be given to one or two points. The declination is marked on each line. Thus, the line passing through England, for instance, is marked 25°, and that passing north-west of the British Islands, 30°. At places under those lines, the needle points to a north 25° and 30° west of the true north.

On the space intervening between these lines, including Scotland and Ireland, a correction, varying from 0° to 5°, must be made according as the station lies more towards the one line than the other. The westerly line of no declination passing northward cuts off the eastern corner of South America, proceeds to North America, which it enters at North Carolina, traverses the continent by Lakes Erie and Huron and the west of Hudson's Bay, and ends in the north of the continent at Boothia. The easterly line of no declination passing southward enters Europe in the north of Russia, crosses the White Sea, the east of Russia, of the Caspian Sea, of Persia, and the Arabian Sea; then turns eastward, and cutting off the west of Australia, passes southward. The space included between those two lines, and which in the chart is left untinted, constitutes, so to speak, the hemisphere of westerly declination. It includes the east of the two Americas, the Atlantic Ocean, the whole of Europe and Africa, and the west of Asia and Australia. The rest of the earth, which in the chart is tinted, has an easterly declination. There is an elliptic space in Eastern Asia, which is left white, having a westerly variation, and forms an exceptional region in the eastern magnetic hemisphere.

It will be seen that the lines converge in the north of North America, and in the south of Australia. So far as experience goes, and so far as the most matter-of-fact theory (Gauss's) teaches, the convergence in both cases is to a point. The point in North America is the *north magnetic pole*, and that south of Australia is the *south magnetic pole*. At these points, then, all isogonic lines converge, and a compass-needle lies indifferently in any position.

The isogonic lines, as seen from the chart, form a somewhat complicated system. This arises from the fact, that we refer the indications of the needle to the geographical poles, which are, so far as we know, arbitrary or extraneous as regards terrestrial magnetism. Duperrey, by drawing what he calls *magnetic meridians and parallels*, draws a system of lines which have much the same conformation with regard to the magnetic poles that the meridians and parallels of latitude have to the geographical poles. A magnetic meridian, according to Duperrey, is the line that would be described by a person setting out, say from the south magnetic pole, and traveling always in the direction of the magnetic north till he reached the north magnetic pole. The magnetic parallels are lines drawn at right angles to the magnetic meridians.

In fig. 2, the isoclinic lines, by the same author and for the same epoch, are given. In the upper part of the chart, which is left white, the north end of the needle dips; and in the lower part, which is tinted, the south end of the needle dips. The amount of dip is marked on each line. Thus, the line passing through the center of England is marked 70°. A dipping-needle, at any place cut by the line, is inclined 70° to the horizon. The line 75° passes to the north of the British Isles. In Ireland and Scotland, therefore, the dipping-needle has an inclination greater than 70°, and less than 75°. The line marked 0° is the line of no dip; at any station on it the dipping-needle is horizontal. This line is called the *magnetic equator*. It will be seen that it is not coincident with the geographical equator; it is not even a great circle of the earth, but is an irregular curve cutting the equator in two points, one near the west coast of Africa, and the other in the middle of the Pacific Ocean. The points on the earth's surface where the dipping-needle stands vertical, and where, in consequence, as before mentioned, the compass-needle lies in any direction, are called the magnetic poles.

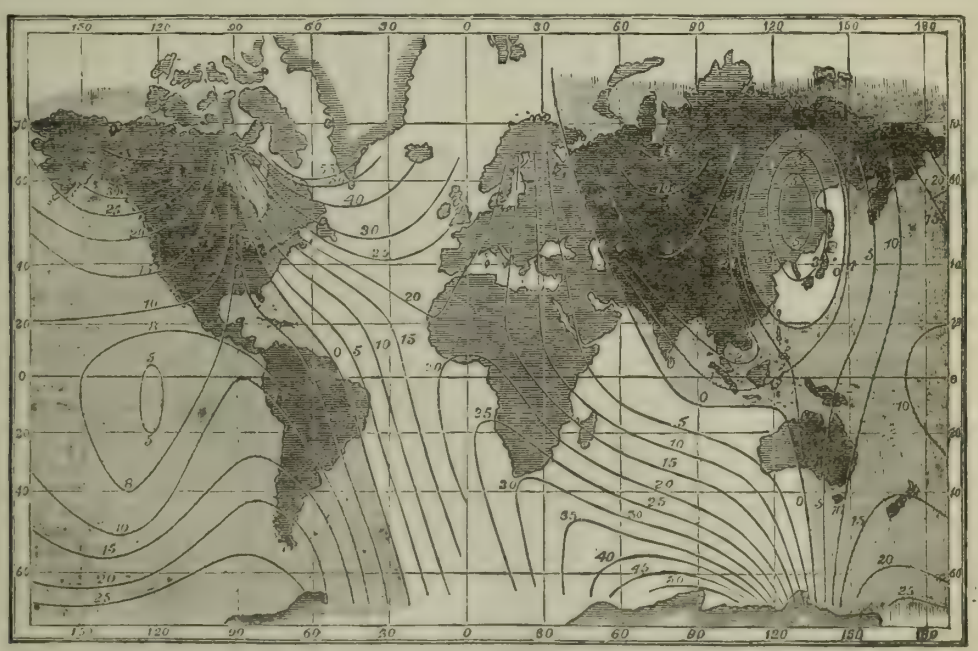


Fig. 1.

The north magnetic pole was found in Boothia Felix by Captain Ross at 70° 5′ N. lat., and 263° 14′ E. long. According to Gauss's calculation, it should have been at the time (1831) some 3° north of this point. From observations made at Hobart Town, the nearest station to it, the south magnetic pole should lie 66° S. lat. and 146° E. long. These points are not diametrically opposite each other, as the geographical poles. If the lines of equal dip were drawn on a globe, they would form round the magnetic poles a system of irregular circles, somewhat resembling that of the parallels of latitude round the poles of the earth.

We do not add an isodynamic chart, as it would take up too much space. Colonel Sabine's Dynamical Chart, along with the isogonic and isoclinic charts, will be found fully engraved and explained in Johnston's *Physical Atlas* (new edition). From this

chart we learn that the magnetic intensity is least in the vicinity of the magnetic equator, and increases as we approach the magnetic poles. The lines of equal intensity, though running much in the same direction as the lines of equal dip, are neither coincident nor parallel with them. The line of least intensity, itself not an isodynamic line, runs nearly parallel to the magnetic equator, but lies, except in the western half of the Pacific, a few degrees to the south of it. We thus learn that the changes in direction and intensity do not march together. We should fancy that at that point or points on the earth's surface where the dipping-needle stood erect, we should be nearest to the center of free magnetic energy, and that there the force would be greatest; but this is not the case. The point in North America where the intensity is greatest, is situated to the west of Hudson's Bay, some 18° south of the north magnetic pole. But this is not the only point of maximum force in the north magnetic hemisphere. There is another, which was found by Hansteen in 1828, in Northern Siberia, about the longitude 120°. This maximum point is weaker than the American, in the proportion of 100 to 107 (Sabine).

According to Gauss, there can only be one maximum point in the southern hemisphere, which is stronger than either of the other two. It lies north-east of the south magnetic pole, and its intensity is 137 (Gauss) compared with 107, that of the principal northern center. At none of those points does the dipping-needle stand erect. This want of coincidence of the points of vertical dip and of maximum intensity has led to some confusion in the use of the term magnetic pole; some writers meaning by it a point of vertical dip, and others a point of maximum intensity. In adopting the former definition, we are only adhering to the popular meaning of the word, and to the opinion of Gauss, perhaps the greatest authority on the subject. Some of the best English authorities, however, attach to it the latter meaning.

Although the total intensity increases as we go northward or southward from the line of least intensity, the horizontal intensity diminishes. This arises from the fact, that the greater the dip the less the horizontal intensity. Hence the compass-needle,

Year.	Declination.
1576	11° 15′ easterly.
1657—1662	0° 0′ no declination.
1760	19° 30′ westerly.
1815	24° 27′ 18″ westerly.
	Maximum.
1850	22° 29′ 30″ westerly.
1865	21° 6′ "
1875	19° 33′ "
1882	18° 20′ "

Year.	Inclination.
1720	74° 42′
1780	72° 8′
1800	70° 35′
1830	69° 38′
1850	68° 48′
1865	68° 9′
1875	67° 47′
1882	67° 32′

At present, the annual decrease of declination at Kew is 8′. At this rate it would take rather more than 84 years for the compass-needle to shift through a whole point. From the observations of the dip, we find that it has been gradually decreasing for the last 150 years. The annual decrease of dip is at present about 2′·6. The time during which observations have been taken of the declination and dip is far from comprehending a cycle of change in either, and it is a mere matter of speculation how long that may take. The magnetic history of London does not apply to other places; each place, so far as has been ascertained, having a magnetic history of its own. Thus, in Paris, the time of no declination was 1669; and of maximum declination, 1814; the latter amounting to 22° 34′ W. Every place, according to Barlow, appears to have its own magnetic pole and equator. Magnetic intensity has been observed for so short a time, that little as yet is known of its secular variation. At present, the horizontal intensity is increasing in Europe, but that may arise partly from decrease of dip.

The magnetic elements are also subject to changes, which have a yearly and a daily period. In describing these shortly, we shall limit ourselves to the changes affecting declination, as these are of most general interest. The following are the chief particulars of the *annual variation* of declination given by Cassini: From April to July, or from the vernal equinox to the summer solstice, the western declination decreases. From the summer solstice to the

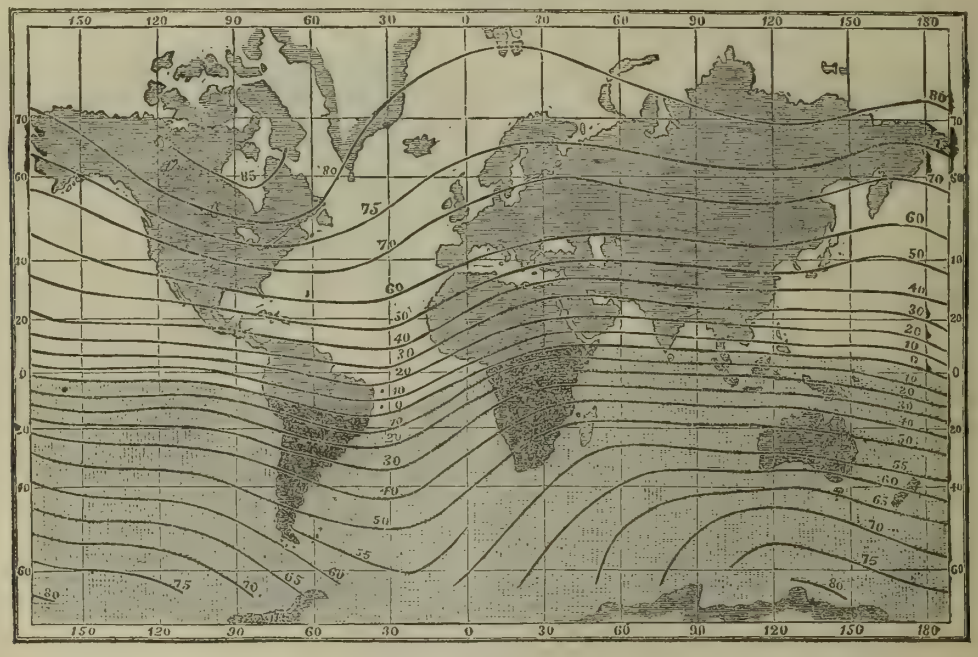

Fig. 2.

which is affected alone by the horizontal intensity, oscillates more sluggishly as we leave the line of least intensity. A dipping-needle, for instance, oscillates faster at London than at Calcutta, because the total intensity which affects it is greater at London than at Calcutta; but with a compass-needle it is the reverse, from the horizontal intensity being greater at the latter than at the former station.

Variations of the Needle.—The magnetic elements do not remain constant in the same place, but are subject to continual though small variations. These are regular and irregular. Under regular variations are included *secular*, *annual*, and *diurnal* variations. The secular variations take centuries for their completion. The following list of the declination and dip at London in different years will give an idea of the secular variations for these elements

vernal equinox, that is, during the other nine months of the year, the declination increases, the needle turning to the west. Its position in May and in October is nearly the same; so that in the winter months, from October to April, the westerly motion is slow The range of the annual variation at Kew is 58′·85.

The mean *diurnal variation* for Kew is shown in fig. 3. The irregular line indicates the course of the north end of the needle. A rise of this line indicates a change of the north end to the east; a fall, a change to the west. The interval between two horizontal lines corresponds to a deflection of the needle 1′ to the east, and a fall 1′ to the west. The line marked *o* is the magnetic meridian, or the mean daily position of the needle. The interval between two upright lines corresponds to an hour. The course begins at twelve at night, and ends at twelve the following night. At twelve at night, the magnet is 1¼′ east of the mean position,

and continues nearly in the same position, with only a slight westerly deviation, till 15 hours (three in the morning), when it veers eastward. At 20 hours (eight in the morning), it reaches its furthest east point. From eight in the morning till one in the afternoon, it makes a sweep of 10′ towards the west, and then stands about 6′ to the west of the mean. After one, it goes west-

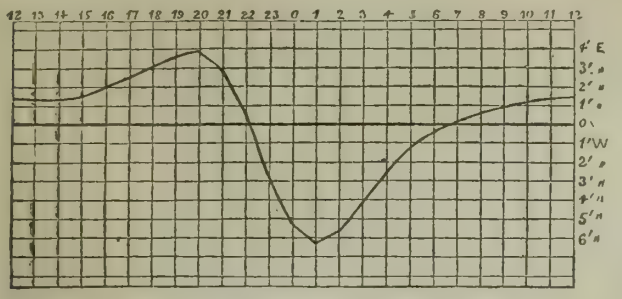

Fig. 3.

ward till midnight, when it again begins the same course. The needle stands in its mean position a little after ten in the morning, and a little before seven in the evening. The course here described is the course for the year. But the diurnal range is different in different months. In May, for instance, the average range between the extreme points is 12′, which is the maximum range for the year; and in December, when it is a minimum, it is only 5′ 28″. The diurnal changes here described for Kew are much the same all over the north magnetic hemisphere. The amount, however, is different. Near the magnetic equator the diurnal variation is little or nothing, and it increases as we go northward. Captain Duperrey states that at or near the magnetic equator, the north point of the needle in the morning shifts slightly east or west of the mean, according as the sun passes south or north of the station. In the southern magnetic hemisphere, the daily motions of the needle take place much in the same way as in the northern hemisphere, only the south pole takes the place of the north pole, and the direction of the deflections is reversed. The correspondence, and at the same time opposition, of the southern hemisphere is also shown from the time of maximum and minimum range. When the sun is in the northern signs of the zodiac, the range is a maximum in the northern, and a minimum in the southern hemisphere; and when the sun is in the southern signs, the reverse takes place. The diurnal variation is so small, that the ordinary compass-needle is not delicate enough to show it.

The *irregular variations* are those which break in upon the regular march of the diurnal variation, without in the main altering it. Instead, for instance, of the needle steadily going westward from 8 A.M. to 1 P.M., as shown in fig. 3, it makes, when affected by irregular variation, deflections eastward as well as westward, although it in the main moves westward; so that the line between these hours, instead of being comparatively straight, would be an irregular zigzag. These disturbances of the mean course are sometimes considerable, amounting even to one or two degrees in extreme cases. On some days, the mean diurnal course is much disturbed, on others, very little; but it is never quite free from them. It has been found that places of the same longitude have similar disturbances at the same time; that those on opposite sides of the globe, or differing by 180° of longitude, have disturbances equal in amount, but opposite in direction; and that those situated 90° west or east of the disturbed regions, have little or no disturbance. The appearance of auroras is invariably accompanied by magnetic irregularities, and their effect extends far beyond the regions where they are visible. Earthquakes and volcanic eruptions have also a marked effect in this way. Humboldt gave the name of *Magnetic Storms* to these irregular disturbances. The frequency of these storms, and the amount of the diurnal variation, are found to be greatest when sun-spots are most numerous. See SUN.

1. *Theories of Terrestrial Magnetism.*—The earliest theory was that suggested by Gilbert, in which it is supposed that a magnet in the middle of the earth extends from one magnetic pole to the other. On this supposition, the general phenomena of terrestrial magnetism may be accounted for—a needle both by declination and dip, must point to the poles. This must always remain, from its simplicity, the popular theory on the subject. In consistency with his theory, Gilbert considered the north pole of the magnet to be a south pole, as he took the north pole of the earth for his standard north pole. If this theory were correct, the magnetic equator would be a great circle of the earth, and the magnetic poles would be 90° from it, which is far from the case. It is only a rough approximation to a just theory.

Halley endeavored to supplement Gilbert's theory, by supposing two magnets of unequal strength crossing each other at the earth's center to be the cause of terrestrial magnetism. The theory of the two magnets or four poles was ably defended by Hansteen.

Barlow considered that the earth acted on the needle as if currents of electricity traversed it from east to west. He imitated its action by wrapping a wire in parallel coils round a wooden globe, and causing a galvanic current to pass through it. Each turn of the wire represented a magnetic parallel, and the two ends of the coil the magnetic poles; and to complete the analogy, the globe was movable on an axis, which stood in the same relation to the ends of the coil as the astronomical to the magnetic poles of the earth. When a small needle was placed on the globe, its declination and dip bore a striking resemblance to those of a needle similarly situated on the earth's surface. The objection to this theory is the difficulty of accounting for the origin of such currents in the earth. To meet this, some suppose the earth to be a huge thermo-electric pile; as the heat of the sun falls on one side of it, currents are there generated which travel round the globe. But how, again, it may be asked, are the conditions of thermo-electricity implemented by the materials of the earth? This question still remains to be answered.

The close connection between temperature and magnetism is shown by the diurnal variation of declination, the epochs of which closely correspond with those of the daily temperature, and by the fact, that the isodynamic and isothermal lines manifest a marked correspondence. Sir David Brewster has also shown that there are two centers of maximum cold in the northern hemisphere, which are situated near to the two intensity poles.

Gauss did not start from any simple supposition of one or two magnets giving rise to the magnetism of the earth, nor did he assert or deny its electric origin. Considering the whole earth as magnetic, he aimed at determining how it must act as a whole at the different points on its surface. In order to make the equations he obtained theoretically in this attempt express the distribution on the earth, the magnetic elements of eight stations at a sufficient distance from each other on the earth's surface had to be ascertained and substituted in these equations. This done, from the longitude and latitude of any station he considered himself prepared to deduce its magnetic elements. The magnetic charts which he sketched, though founded on the imperfect observations to which he had access, are singularly in keeping with fact, and go far to establish the correctness of his reasonings.

The secular variations are as yet wholly unaccounted for. The cause of the diurnal variation is universally attributed to the sun. Secchi, who carefully studied the diurnal variation of the needle, considers that the sun, so far as they are concerned, acts upon the earth as a powerful magnet at a distance.

Historical Sketch.—The discovery of the change in declination at different places is generally attributed to Columbus, and was one of the many important observations of his memorable voyage across the Atlantic. Robert Norman, an instrument-maker in London, first discovered the dip of the needle in 1576. He was led to it by finding that needles nicely balanced before magnetization had to be slightly loaded on the south end, to keep them horizontal after being magnetized. Gilbert (1600) gave the first theory of terrestrial magnetism, viz., that of the single magnet. Halley, the astronomer-royal, published his theory of the four poles in 1683. In 1688 and 1689, at the expense of government, he made two magnetic voyages, the results of which he embodied in his charts of the lines of equal declination, published in 1701, which were the first magnetic charts ever published. In 1722, the diurnal variation was discovered by Graham, the celebrated instrument-maker of London. The first inclination chart was published by Wilke at Stockholm, 1768. Humboldt inaugurated the present system of careful observations of terrestrial magnetism by taking comparative measurements of the magnetic elements at Peru and Paris (1799—1803). Hansteen's work on the *Magnetism of the Earth* was published at Christiania, 1817; in 1826 he published the first isodynamic charts. Barlow (1831) suggested the electric origin of terrestrial magnetism. In 1831, Captain Ross came upon the north magnetic pole. In 1835, stations were established throughout Europe, and the observations were published by Gauss and Weber, 1836. Gauss (1833—1840) perfected his theory. In 1837, Colonel Sabine published an isodynamic chart of the whole globe. Observations were made (1840—1854 at stations throughout the British Empire by British officers, under the direction of Colonel Sabine.

TERRESTRIAL TEMPERATURE. The distribution of heat over the globe is represented by isothermal lines, or lines drawn through all places having the same mean temperature. The mean annual temperature is shown by the lines in fig. 1, and the warmest and coldest months in fig. 2, the dotted lines showing the mean temperature for January, and the solid lines the temperature for July.

The part of the globe having the highest mean annual tempera-

ture forms an irregularly shaped belt, lying along the equator, and comprised between the north and the south isothermals of 80°. On either side of this warm belt, the temperature diminishes towards the poles; and the lines showing successively this diminution are, speaking in a very loose sense, arranged parallel to the equator, thus showing the all-predominating influence of the sun as the source of terrestrial heat. The coldest portion of the earth's surface is a small oval-shaped patch near to but not surrounding the north pole, its mean temperature being —4°. Its narrowest diameter lies north and south, nearly touching the pole on the one side, and extending on the other as far south as 72°·30 N. lat. in 130° W. long. Part of it is seen in the diagram. On looking at the isothermal of 0°, one might be led to suppose that there are two centers of greatest cold, one north of Siberia, and the other north of British America. Such, however, is not the case—the apparent double center of greatest cold being solely due to the isothermals being drawn on Mercator's projection of the earth; for if an isothermal map be drawn on a polar projection, the lines of mean annual temperature enclose one connected space of greatest cold, and not two such spaces, as is not unfrequently stated.

While the decrease of temperature in advancing towards the poles corresponds in a general way to what may be called the solar climate, there are deviations brought about by disturbing causes too important to be overlooked. These disturbing causes are (1) the currents of the sea; (2) the prevailing winds; and (3) large surfaces of water which are frozen during part of the year.

The influence of an oceanic current depends on the temperature of the place it leaves and the place at which it arrives. Hence the great equatorial current, flowing from east to west, does not require to be considered here, because the heat remains the same throughout its course; but only those currents which convey the waters of the sea to higher or to lower latitudes. Of these, the most marked and important is the Gulf Stream in the North Atlantic, which, by conveying warm water to the arctic regions, pushes the isothermals many degrees to the northward. There is a similar, though much feebler, current passing from the North Pacific to the Arctic Sea through Behring's Strait, and there, accordingly, the isothermals are pushed a little to the northward. In the southern hemisphere, there are two currents, one discovered by Humboldt, passing from the Antarctic Ocean northward by the coast of Peru as far as Lima; the other flowing from the Cape of Good Hope northward along the west coast of Africa: these currents, flowing from colder to warmer latitudes, lower the temperature, and thus drive the isothermals towards the equator. Again, the great equatorial current, after impinging on the east coast of Africa, turns southward, and by the warmth it imparts, pushes the isothermals into higher latitudes. For the same reason, the current flowing southward past the coast of Brazil, raises the temperature in the east of that country.

The influence of these great currents is more distinctly marked in the forms of the isothermals for January and July. Thus, in January, when the relative excess of the temperature of the Gulf Stream is greatest, the isothermals are driven very far to the north; and similarly in the southern hemisphere, the currents from the Antarctic Ocean being coldest in July, the isothermals are deflected more towards the equator during that month. The most remarkable lowering of the isothermals occurs in Labrador and Newfoundland during May and June, and is caused by the icebergs which then descend on these coasts from Davis' Strait.

Since winds bring with them the temperature of the regions they have crossed, the equatorial current is a warm wind, and the polar a cold wind; also winds arriving from the ocean are not subject to such variation of temperature during the year as winds from a continent. As an atmosphere loaded with vapor obstructs both solar and nocturnal radiation, it follows that moist winds are accompanied with a warm temperature in winter, and a cool temperature in summer; and dry winds with cold winters and hot summers. The direction of mountain-ranges is also an important element to be taken into account in estimating the influence of winds on temperature. These considerations explain the position of the isothermals in the north temperate zone, where the prevailing wind is the south-west or anti-trade (see WINDS). In January, the western parts of each continent enjoy a comparatively high temperature, from their proximity to the ocean, whose high temperature the winds waft thither; and they are further protected from extreme cold by their moist atmosphere and clouded skies. But in the interior of the continents it is otherwise; for the winds getting colder as they advance, and being deprived of their moisture as they cross the mountains in the west, the soil is exposed to the full effects of radiation during the long winter nights, and as a consequence the temperature rapidly falls.

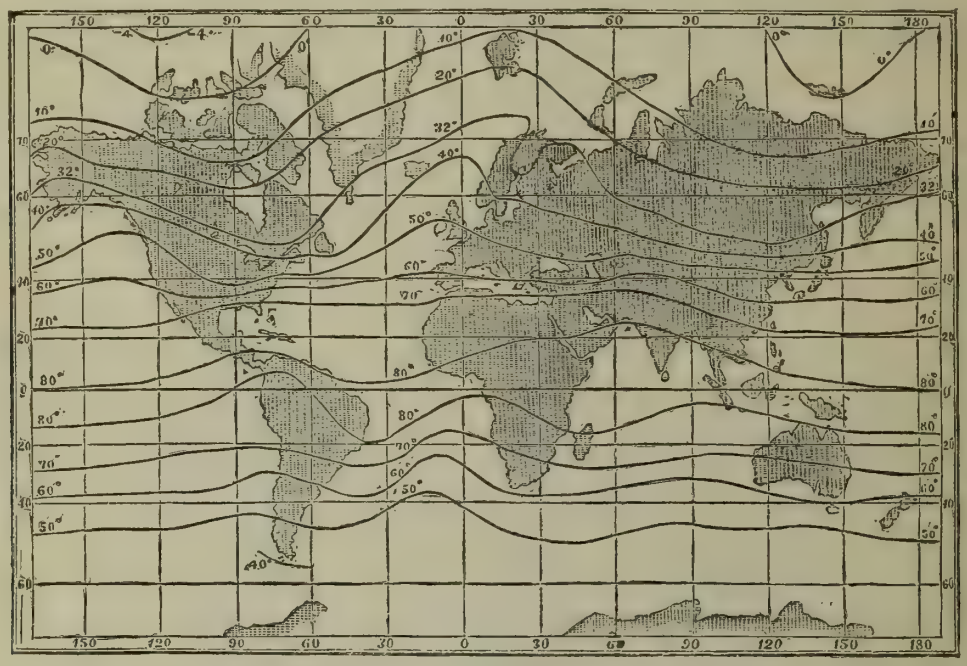

Fig. 1.

In the center of Siberia, the January temperature falls to —40°, which is 9° colder than the coldest part of the American continent; and this center of greatest cold lies near the eastern part of the continent of Asia. On the other hand, in July, the interior of continents is much warmer than their western parts. Hence the interior and eastern parts of Asia and America are characterized by extreme climates, and the western parts by equable climates. Thus, at Yakutsk, in Siberia, the July temperature is 62°·2, and the January —43°·8 the difference being 106°·0; whilst at Dublin these are respectively 60°·8 and 38°·5, the difference being only 22°·3. This constitutes the most important distinction of climates, both as respects vegetable and animal life. On man especially the effect is very great—the severity of the strain of extreme climates on his system being shown by the rapidly-increasing death-rate as the difference between the July and January temperatures increases.

The great fresh-water lakes of North America—Lakes Superior, Huron, Erie, Michigan, Ontario, Bear Lake, &c.—exercise an important influence on the climate of the central parts of North America, for in winter, America, with its frozen lakes, is a truly unbroken continental mass, and its winter climate is therefore continental; whereas in summer its numerous large sheets of fresh water communicate to it many of the features of an insular summer climate.

The whole effect of the disturbing causes is seen at once, if we compare the observed temperature of a place with its normal temperature, that is, the temperature due to it in respect of its latitude. In the northern hemisphere, in January, the sea and the western parts of the continents are in excess of their normal temperature; elsewhere, there is a deficiency. There are two centers of excess, one to the north-east of Iceland, amounting to 41°; the other in Russian America, amounting only to 18°; and two centers where the temperature is deficient, one at Irkutsk, amounting to 41°; and the other west of Hudson's Bay amounting to 27°. In July, the United States, Europe, Asia, the Indian Ocean the north of Africa, and the extreme north of South America, have their temperature in excess, while elsewhere it is deficient. The centers of excess are, north of Siberia, 13°·5; Red Sea, 11°·0; and north-west of the United States, 4°·5; and the centers where the temperature is deficient are, the entrance to Hudson's Bay, 11°·0; and the Aleutian Islands, 11°·0.

As to *underground temperature*, the protracted investigation of a committee of the British Association (who had data, widely differing, from very various deep mines and borings in remote parts of the earth) led to the conclusion that a descent through 64 feet through the crust of the earth corresponds to a rise of 1° Fahrenheit.

Fig. 2.

TERRIER, a small kind of dog, remarkable for sagacity, vivacity, courage, and eagerness in the pursuit of 'vermin,' which it readily follows into burrows, from Lat. *terra*, the earth (hence the name). It will readily attack animals much larger than itself. Terriers are of great use for killing rats in places much infested by them. They are also used for compelling the fox to leave his retreat; and a large variety called the *Saufinder*—that is, Boar-

Scotch and English Terriers.

seeker—is employed in Germany to rouse the fiercest beasts of the forests from their lairs. The varieties of T. are numerous. In Britain, two are particularly prevalent, known as Scotch and English terriers—the former with long, rough, wiry hair, with which even the face is much covered; the latter with smooth, short hair. The ears are either erect and pointed, or have pendent tips. The Skye T. is a breed of Scotch T., peculiarly prized. If any kind of dog may be regarded as truly indigenous in Britain, it is the T.; but there is no certainty that it was not imported by the first inhabitants. Dogs very similar have existed in the north of Europe in a domesticated state from remote antiquity. The BULL T. is probably a cross between the T. and the Bull-dog (q. v.).

TERSCHE'LLING, one of the chain of islands to the north of Holland, lies in 53° 24′ N. lat., the principal villages being Oosterschelling, Westerschelling, and Midsland. It consists of fertile arable and meadow lands, is protected on the south by large dykes, and in other parts by downs, which are carefully preserved. Area about 45 sq. miles. Pop. 3128. There is a good haven, a shipbuilding-yard, a woollen dyework, &c. T. was the birthplace of Barentz, the explorer.

TE'RTIAN FEVER. See AGUE.

TE'RTIARY (Lat. *Tertiarius*, one of the third rank), a name given by church writers to a class in the Roman Catholic Church, who, without entering into the seclusion of a monastery, aspire to practise in ordinary life all the substantial obligations of the scheme of virtue supposed to be laid down in the Gospel. Whatever earlier traces of this institution may be observable, there is no dispute that it was under St. Francis and the mendicant orders generally that the institute of T. reached its full development. The rules of the institution of T., such as they have since substantially been maintained, were made public in 1221. The associates must, of course, all be members of the church; and it is moreover required that all shall be of good repute and blameless life. The intending members must restore all ill-gotten goods, must renounce all evil practices, and abandon all feuds and enmities with their neighbors. Wives cannot be received without the consent of their husbands. The obligation of T. once accepted, is irrevocable, unless the party should be released, or should enter into a more strict religious order. The members are required to renounce luxury of life, profane exercises and amusements, costly or unseemly dress, and the use of arms, except in the necessity of self-defence. They must frequent the sacraments; hear mass, if possible, daily; observe the fasts of the church, as well as certain special austerities; avoid contention, litigation, and unnecessary oaths; cultivate charity towards all, with special obligation towards needy, sick, or afflicted brethren, and practise with more than common fervor the great Christian virtues.

The T. are placed under the authority of superiors elected at intervals, and for a stated period, and are liable to an annual visitation, conducted by a priest appointed for the purpose. It is to be observed, however, that none of these obligations were supposed to bind the members under pain of mortal sin.

Such was the celebrated institute of the T., or the Third Order of St. Francis. Similar lay associations were organized in connection with the Dominican, Carmelite, and Augustinian, as well as with certain of the more modern orders; and a brotherhood of the same character had already been formed by the Templars. It ought to be added, that the T. institute, properly so called, is quite distinct from that of the lay 'confraternities' which exist in connection with the several orders, and the objects of which are very similar.

TERTIARY, the term applied in the science of Geology (q. v.) to all the strata of the earth's crust above the Cretaceous Rocks, with the exception of those superficial beds which have recently been raised to a distinct group, under the title of the Quaternary System, or Recent Period. There is considerable difference of opinion as to the division-line between the two systems, some including the boulder-clay and its associated beds in the one, and some in the other group. Tertiary is synonymous with Cainozoic, and is divided into the Pleiocene (q. v.), Meiocene, and Eocene (q. v.) periods.

TERTU'LLIAN, a Father of the church, and one of the earliest who used the Latin language in written compositions. In one passage, the genuineness of which there is no reason to doubt, he calls himself Septimius Tertullianus. The best manuscripts call him Quintus Septimius Florens Tertullianus. He was the son of a proconsular centurion—that is, a centurion who attended on the proconsul. He was born in Carthage. He was brought up a heathen, and from his own writings we learn that he was licentious in his conduct, and fond of the public shows. We know nothing more of his heathen life. Eusebius describes him as a man exceedingly well acquainted with the laws of the Romans, and his writings bear out the assertion. From this circumstance, some have identified him with a Tertullianus whose name occurs in the index of the Pandects, and have supposed that he acted as an advocate; but the supposition is a mere conjecture. We know nothing of his conversion. He became a presbyter in the church, but whether he held this office in Rome or in Carthage, is matter of dispute, and there are no data to determine the question. It is certain that he visited Rome, and was well acquainted with the affairs of the Roman Church. He also married; and as his wife was a Christian, it is supposed that his marriage took place after his conversion. After remaining a presbyter until he had reached middle age, he became a Montanist. Jerome attributes his adoption of Montanism to the insulting treatment which he received at the hands of the Roman clergy. But this is not likely an entirely accurate account of the matter. Jerome himself had been ill treated by the Roman clergy, and was therefore inclined to blame them; and in the character and general tendency of T.'s opinions, we have ample explanation of his passing over to Montanism. See MONTANUS. He lived to a good old age, remaining a Montanist to the last. We have no clue to precise dates in the history of Tertullian. Jerome states that he flourished under Severus and Antoninus Caracalla. Allix places his birth at 145 or 150 A.D., and his death at about 220 A.D.; but these are conjectures.

T. was a man of strong and violent passions; he loved and hated with intensity. He possessed considerable culture, and was well versed in Roman law, in ancient philosophy, history, and poetry. He was not deficient in philosophical power, but he was narrow, bigoted, and uncharitable. He shows no sympathy with Greek speculation or with freedom of human thought; and he shows little sympathy with the joys and pleasures of man, being strongly inclined to asceticism. We need not wonder, therefore, that he came to believe in the Paraclete of Montanus as the revealer of the perfection of Christianity, and that he adopted the Montanist opinions, that second marriages were adulteries, and that it was unlawful to flee in times of persecution, and wrong to receive the lapsed back into the communion of the church.

His writings are numerous. Attempts have been made to divide them into those which were written before he became a Montanist, and those written after that event; but the attempts have failed; for in treating many subjects he would have no occasion to say a word in regard to the Paraclete, second marriages, or persecution.

His works are interesting, throwing much light on the internal circumstances of the church, on the social questions which perplexed Christians, on the opinions of heretics, and on the development of doctrine. Of his theology, Neander remarks: 'In Tertullian we find the first germ of that spirit which afterwards appeared with more refinement and purity in Augustine, as from Augustine the scholastic theology proceeded, and in him also the Reformation found its point of connection.' Among the peculiar opinions which he held, may be mentioned his belief in the corporeality of the human soul.

His writings had great influence on the subsequent ages, but especially on Cyprian. Jerome says: 'I saw at Concordia, in Italy, an old man named Paulus. He said that, when young, he had met at Rome with an aged amanuensis of the blessed Cyprian, who told him that Cyprian never passed a day without reading some portion of Tertullian's works; and used frequently to say: *Give me my master*, meaning Tertullian.'

There are many editions of Tertullian; the best is by Franciscus Oehler (3 vols. 8vo, Lps. 1853). The third volume contains the principal dissertations on the life and writings of Tertullian. The works of T., with many dissertations and notes, form the first and second volumes of Migne's *Patrologia Latina*. The English reader will find a full and satisfactory account of T.'s life, writings, and opinions in Bishop Kaye's *Ecclesiastical History of the Second and Third Centuries, Illustrated from the Writings of Tertullian* (8vo, 2d ed., Cambridge, 1829); and in Neander's *Antignosticus*, or *the Spirit of Tertullian*, translated by J. E. Ryland. A good translation of T.'s works will be found in Clark's *Anti-Nicene Christian Library*, edited by Drs. Roberts and Donaldson.

TE'SCHEN, a town of Austrian Silesia, on the right bank of the Olsa, 38 miles east-south-east of Troppau. Pop. (1880) 9267. Here, in 1779, a treaty of peace was concluded between Maria-Theresa and Frederick II., by which the dispute of the Bavarian Succession was brought to an end.

TE'SSERÆ, the small square tiles or cut stones used in forming tesselated pavements.

TEST ACTS, otherwise called *Corporation Acts*, the popular name given to two English statutes imposing certain oaths on the holders of public offices. Act 13 Car. II. c. 2, directs that all magistrates shall take the oaths of allegiance and supremacy, as well as an oath renouncing the doctrine that it is lawful to take arms against the king, and provides that they must receive the communion according to the rites of the Church of England within a year before their election. Act 25 Car. II. c. 1, imposed the like conditions on the holders of all public offices, civil and military, and obliged them in addition to abjure all belief in the doctrine of transubstantiation. These acts, which were practically evaded to a large extent by means of an act of indemnity passed every year, were repealed by 9 Geo. IV. c. 17, in so far as regarded the administration of the sacrament, for which a declaration set forth in that act was substituted.

A statute of William IV. substituted a declaration for an oath in most government offices. A new form of oath has been substituted for the oaths of supremacy, allegiance, and abjuration by 21 and 22 Vict. c. 48.

TE'STAMENT. See BIBLE.

TESTAMENT. See WILL.

TESTA'TUM is one of the clauses of an English deed, otherwise called the Witnessing or Operative part, commencing at the words, 'Now this indenture witnesseth that,' &c.; and it includes a statement of the consideration-money and the receipt thereof.

TESTER, or TESTOON, a flat canopy over a tomb, pulpit, &c.

TE'STICLES. See REPRODUCTION.

TESTIMO'NIUM, in an English deed, otherwise called the Attestation Clause, is that part which states that the party signed the deed, beginning with the words, 'In witness whereof.'

TESTING, in Chemistry, embraces a series of processes, the details of which would occupy far more space than the general plan of this work would admit of. Indeed, testing may be regarded as equivalent to qualitative analysis. As a simple illustration of the process of testing, we will assume that the most common of all chemical compounds, a salt, is submitted for examination. The student must pursue some such course as the following: 1. He must examine the dry substance before the blow-pipe, and note whether (*a*) it is volatile, as are the salts of ammonia and mercury; or (*b*) fusible, as are the salts of potash and soda; or (*c*) infusible, as are the salts of zinc, alumina, magnesia, lime, strontia, and baryta; or (*d*) reducible, as are the salts of silver, tin, lead, bismuth, antimony, and cadmium; and (*e*) whether it gives a coloration to the borax bead, and what that color is.

2. Having made his blow-pipe examination, he must bring his substance to a finely-divided state, and dissolve it, if possible, in water, and if it is insoluble in that fluid, even with the aid of heat, in hydrochloric or nitric acid. The solution, whether in water or acid, to which no test or reagent has been applied, is termed by Odling (*A Course of Practical Chemistry*, 2d ed., 1865) and others *the original solution;* and to this are added various tests, such as sulphuretted hydrogen, hydrosulphate of ammonia, ammonia, nitrate of silver, &c. The most common effect resulting from the addition of a gaseous or liquid reagent is to cause a *precipitate* or solid deposit of either the base or acid sought for. These precipitates differ in their color, consistency, &c.; and the student must note not only the color of the precipitate (although this is the most important point), but also whether the deposit is crystalline, gelatinous, clotty, &c. 3. He must then ascertain to which group the base he is seeking for belongs. There are three great groups of bases; the members of the first group being precipitated from

their acid or acidified solutions by sulphuretted hydrogen (hydrosulphuric acid); those of the second group not being thrown down by this reagent, but being precipitated from neutral solutions by hydrosulphate of ammonia (sulphide of ammonium); while those of the third group are not thrown down by either of these reagents. The first group includes tin, arsenic, antimony, bismuth, mercury, lead, silver, copper, and cadmium; the second, nickel, cobalt, manganese, iron, chromium, aluminium, and zinc; and the third, barium, strontium, calcium, magnesium, potassium, sodium, and ammonia. (See Odling, *op. cit.*, p. 64.) 4. Having ascertained to which base the group belongs, the next point is to identify it. For information on this point, the reader is referred to any of the standard works on qualitative analysis, or on practical chemistry. 5. The base being thus determined, it remains to determine the acid, and in searching for it, the student will be much assisted by a knowledge of the solubility of the most important classes of salts.

Knowing, for example, the insolubility of the sulphates of baryta and strontia, he need not search for sulphuric acid in a soluble salt of one of these earths. On the other hand, a salt insoluble in water is not likely to be a nitrate or chlorate, or acetate, or chloride (the only chlorides insoluble in water being chloride of silver and calomel). We cannot enter into the testing for acids further than to observe that the nitrates and chlorates deflagrate; the tartrates and citrates char; the carbonates effervesce when acted on by an acid more energetic than carbonic acid; the silicates, borates, and benzoates are precipitated by hydrochloric acid; and the arseniates and chromates react with hydrosulphuric acid. The presence of any particular acid is more or less indicated by its behavior, while still in union with the base, with strong sulphuric acid, which in many cases causes the evolution of characteristic fumes or vapors; and amongst the tests especially applicable for the detection of the acids (in acid solutions) are solutions of nitrate of baryta, nitrate of silver, chloride of calcium, and perchloride of iron. As the above remarks apply merely to the detection of the base and acid contained in a single salt, it will readily be understood how much the difficulties are increased when there is a mixture of several salts, or where, in place of a metallic oxide, a vegetable base is present, or where we have to deal with a complicated mixture of organic and inorganic substances, as, for example, in the investigation of the contents of the stomach in a case of suspected poisoning.—The following works on the subject may be referred to: Fresenius's *Qualitative Analysis*, Noad's *Qualitative Analysis*, Greville Williams's *Outlines of Chemical Manipulation*, Bowman's *Practical Chemistry*, and Odling's *Practical Chemistry*.

TESTING CLAUSE, in a Scotch deed, is the last clause, which narrates when and where the parties signed the deed, before what witnesses, the number of pages of which the deed consists, and who was the person who penned the deed. Moreover, if there have been any interlineations or erasures of important words during the engrossing, these should be mentioned in this clause. The clause is an essential part of a Scotch deed, and no deed which is written by another than the party is valid unless the testing clause is regular. The usual form is this: 'In witness whereof, these presents, written on this and the five preceding pages by John Smith, residing at, &c., were subscribed by the parties as follows—viz., by the said A. B. at Glasgow on the 26th day of June 1874, before these witnesses, W. X. of, &c., and Y. Z. of, &c.'—In English or Irish deeds, there is no necessity to enumerate these particulars in the attestation clause.

TEST-PAPERS are made by dipping unsized paper into an alcoholic solution of a vegetable coloring matter which changes color when exposed to the action of an acid or alkaline solution. The paper, after being gently dried, is cut into slips of a suitable size. Hence, by dipping the appropriate test-papers into any solution, we can ascertain whether it is acid, alkaline, or neutral. Litmus and turmeric are most commonly used as the coloring matters; litmus for the detection of acids, and turmeric for that of alkalies.

TESTU'DO. See TORTOISE.

TESTUDO, in Ancient Warfare, was a defensive arrangement of the shields, by means of which a body of men advancing against a wall for assault or mining sought to protect themselves from the darts and weapons of the defenders. The men standing in close order joined their shields above their heads, the edges overlapping, until the whole resembled the shell of a tortoise (*testudo*).—The name was also applied to a machine moving on wheels, and roofed over, under which soldiers worked in undermining or otherwise destroying the walls in a siege. See BATTERING-RAM.

TE'TANUS (derived from the Gr. *teinein*, to stretch) is one of the most formidable diseases of the nervous system, and is characterized by an involuntary, persistent, intense, and painful contraction or cramp (see SPASM) of more or less extensive groups of the voluntary muscles, nearly the whole of the body being sometimes affected. There is usually a certain degree of order in which the different sets of muscles are affected. The muscles of the neck, jaws, and throat are almost always the first to give evidence of the presence of the disease. 'The patient,' says Dr. Watson, who has written a most graphic description of this terrible malady, 'feels a difficulty and uneasiness in bending or turning his head, and supposes that he has got what is called a stiff neck. He finds also that he is unable to open his mouth with the customary facility. At length the jaws close; sometimes gradually, but with great firmness; sometimes (it is said) suddenly and with a snap. In four cases, perhaps, out of five, the disease begins in this way with *trismus* or *lock-jaw;* so that this last is the vulgar name for the complaint. Along with this symptom, or very soon after it, the muscles concerned in swallowing become affected; and in a short time there comes on, what is often the most distressing part of the disorder, an acute pain at the lower part of the sternum, piercing through to the back. This pain depends, it can scarcely be doubted, upon cramp of the diaphragm, and is subject to aggravation in paroxysms. The spasm extends to the muscles of the *trunk;* to the *large* muscles of the extremities; the muscles of the *face;* and last of all, in general to the muscles of the tongue, and of the hands and fingers, which often remain movable at the will of the patient, after all the other voluntary muscles of the body have become fixed.'—*Lectures on the Principles and Practice of Physic*, 4th ed., vol. i. p. 568.

The muscles that are affected remain permanently contracted till either recovery or death ensues, and some of them, as, for example, the muscles of the abdomen, are so rigid, as when struck by the fingers, to resemble a board, although a perfect remission of the spasm scarcely ever occurs, except sometimes during sleep. Exacerbations of the spasms, on the other hand, commonly occur every ten minutes or quarter of an hour, usually beginning by an increase of the pain at the sternum, and lasting for two or three minutes: and as the disease advances, these paroxysms become more frequent. The powerful muscles of the back generally overcome the muscles in the front of the body, and when this excess of morbid power in the back is marked, the result is that the patient during the paroxysms rests solely on his head and heels, while his body is raised in an arched form. Occasionally the muscular contraction predominates in the opposite direction, and brings the head and knees in contact; and still more rarely, the body is bent to one side.

During the exacerbations, the face of the patient often presents a positively frightful appearance. The tongue is apt to get bitten during the contractions, which are occasionally so violent as to break the teeth, rupture powerful muscles, and at least in one case, to fracture the thigh-bone. Death usually results from a mixture of causes, but mainly from apnœa (breathlessness), due to the fixed condition of the respiratory muscles, associated with asthenia (loss of power), and flagging of the heart's action.

There are two principal causes of this disease, viz. (1) exposure to cold and damp, and (2) bodily injuries. When tetanus arises from the *first* of these causes, it is termed *idiopathic;* and when from the second, *traumatic*. Idiopathic tetanus is so rare, at all events in this country, that we may pass on at once to the consideration of the traumatic variety. The disease is liable to follow any kind of injury, from a trifling cut or scratch to a compound fracture or the most severe operation, and is much more common in tropical than in temperate climates.

The following table, given by Mr. Poland in his article 'Tetanus' in Holmes's *System of Surgery*, vol. i. p. 306, gives the relative proportions which the occurrence of tetanus bears to various classes of surgical lesions observed at Guy's Hospital during seven years:

There were of—					
Major and minor operations,	1364	cases—tetanus occurred in			1
Wounds of all varieties,.....	594	"	"	"	9
Injuries and contusions.....	856	"	"	"	1
Burns and scalds,..	458	"	"	"	3
Compound fractures,.....	396	"	"	"	9
Total,.....	3668				23

From the large experience thus afforded, it appears that tetanus is most frequently met with in the more severe varieties of injury and accident, such as compound fractures, burns, and injuries to the fingers and toes. It is still a disputed point, whether the seat of the injury forms any special connection with the disease. Hennen, one of our greatest authorities on military surgery, observed it oftener after wounds of the elbow and knee; others, again, more frequently from injuries of the thumb and great toe. There is certainly a popular belief that wounds of the ball of the thumb are especially likely to be followed by tetanus.

The interval between the reception of the injury and the first tetanic symptoms commonly varies from the 4th to the 14th day, and rarely exceeds 22 days, some time in the second week being

the most common period. As a general rule, the more rapidly the disease comes on, the more fatal will be the result.

Mere *trismus* or lock-jaw may be induced by affections of the teeth, especially by difficult dentition of the wisdom-teeth; but this is a purely local affection, in which the muscular contraction, though persistent, is never increased by painful spasmodic paroxysms, and which usually disappears on the removal of the exciting cause; and the general knowledge of this fact may tend to remove unnecessary terrors. Hysteria sometimes mimics the phenomena of tetanus with marvelous fidelity; and hydrophobia and tetanus have been mistaken for one another, in consequence of the spasm of tetanus sometimes affecting the muscles of deglutition, and inducing a fear of swallowing. There is, however, seldom any serious difficulty in detecting the difference between tetanus and any other disease. But there is a form of poisoning which produces almost every symptom of tetanus, and which may be termed *artificial tetanus*. If strychnia or brucia, or their salts, or vegetable matter containing either or both of these alkaloids, as nux vomica, St. Ignatius's beans, or the juice of the upas tiente, be administered, either by the stomach or by inoculation, into the system, it induces all the symptoms of intense tetanus, and there is no test by which to distinguish the results of the disease and of the poisoning, except that, according to Dr. Christison, the disease never proves so quickly fatal as the rapid cases of poisoning with strychnia. See NUX VOMICA. And those who wish to study more minutely the comparative symptoms of strychnia-poisoning and tetanus, may consult the authorized *Report of Palmer's Trial*.

In the way of treatment almost every known medicine has been prescribed, and whatever plan be adopted, a vast majority of the cases terminate fatally. As is the case with certain fevers, so tetanus seems to have a definite course to run; and as Mr. Poland wisely suggests: 'All we can do is to enable our patient to weather out the storm by giving him as much strength as possible, and not adding fuel to the fire by all sorts of applications and internal remedies, which have over and over again signally failed. If we can help our patient on one day after another, we gain much: constant watching and constant attention are required by night as well as by day; an unflinching perseverance on the part of the sufferer in carrying out these views; besides the avoidance of all causes of excitement, and more especially the cold air or winds; taking care to preserve a uniform temperature as much as possible.' When, in consequence of the strong contraction of the muscles of the jaw, it is impossible to open the patient's mouth, food and physic should be introduced into the stomach by means of a flexible tube passed through one of the nostrils.

The peculiar form of tetanus that occurs in newly-born children, differs in so many respects from the disease described in this article, that we shall briefly notice it in a separate article under the title of TRISMUS NASCENTIUM.

TETANUS, or LOCK-JAW, occurs in most of the domesticated animals, but most frequently in horses and sheep. It is usually produced by cold and wet, by intestinal worms, obstinate constipation, or injuries. The symptoms usually come on gradually, involve tolerably equally most of the muscular structures, which become hard and rigid; the nose is protruded, the limbs move stiffly, the tail is upraised, the bowels are constipated. The patient must be kept perfectly quiet, and in an airy but tolerably warm place, and plentifully supplied with cold water, and with soft, sloppy, but tolerably nutritive food, which he will usually greedily suck in through his firmly closed teeth. A full dose of purgative medicine must at once be given; extract of belladonna repeated twice or thrice daily, is occasionally serviceable; any discoverable wound or injury should be fomented or poulticed; bleeding, sedatives, and all causes of irritation must be avoided. In adult animals, most cases are fatal; but amongst young animals, especially when the attack results from exposure to cold, many recoveries occur.

TETE-DU-PONT. See BRIDGE-HEAD.

TETRAGONIA'CEÆ, a natural order of exogenous plants, formerly included in *Mesembryaceæ* (q. v.), from which it differs chiefly in the want of petals. The species are herbaceous plants or small shrubs, with alternate, thick, succulent leaves. A few are found on the shores of the Mediterranean, and some in Asia and the South Sea Islands, but the order abounds chiefly in the south of Africa. New Zealand Spinach (q. v.) belongs to this order. Other species are also used like spinach, as *Sesuvium portulacastrum* and *S. repens* in the West Indies. Species of *Aizoon* are among the plants burned for barilla in Spain and the Canary Isles.

TETRAHE'DRON (Gr. *tettares*, four, *hedr*, a side), one of the five regular geometric solids, is a solid bounded by four equilateral triangles. The best idea of it is gained by considering it as a triangular pyramid, whose three sides and base are equilateral (and therefore equal) triangles. It is a form assumed by some crystals, and in crystallography is considered as a secondary form of the Octahedron (q. v.), produced by removing the alternate angles or edges of the latter.

TE'TRAO AND TETRAO'NIDÆ. See GROUSE.

TE'TRARCH (Gr. *tetrarches*, Lat. *tetrarcha*, 'governor of the fourth part,' i. e., of a country), a title originally designating what is signified by its etymology, the governor of one of four divisions of a kingdom or country; but in the usage of the later Roman Empire, given undistinguishingly to all minor rulers, especially in the east, possessing sovereign rights within their territory, but dependent on the emperor, and in many cases removable at his pleasure. This was especially the case in Syria, where the princes of the family of Herod are called indiscriminately by this title (Luke iii. 1) and by that of king (Matt. xiv. 9). The tetrarch in this latter sense was in truth a sovereign, although a dependent sovereign; and there are instances in which it seems to have been applied to really independent sovereigns of small principalities.

TETTER, the popular name for skin diseases of the kind described under PSORIASIS and HERPES.

TETUA'N, a seaport town and small province on the north coast of Africa, 22 miles south of Ceuta, and 40 miles south of Gibraltar. Area, 914 sq. m.; pop. 17,600. It is surrounded by walls, flanked with towers, and is defended by a castle. Its harbor does not admit large vessels; but a brisk trade is carried on in wool, silk, girdles, leather, cotton, &c., and it exports provisions largely to Ceuta. Oranges are grown in great abundance in the vicinity, and are exported to Spain, Gibraltar, Oran, and recently to England. T. was taken by the Spaniards under O'Donnell (q. v.), February 1860, but was evacuated next year. In a year, above 200 vessels, of 2000 to 3000 tons burthen, enter the port of Tetuan.

TETZEL, or TEZEL (properly *Diez* or *Diezel*), JOHN, well known in connection with the controversy regarding indulgences, out of which the first beginnings of the Reformation took their rise, was born at Leipzig, between 1450 and 1460. His father was a goldsmith of that city. T., after completing the ordinary studies of the period in the university, entered the Dominican convent of St. Paul in 1489, and soon established a reputation as a popular and effective preacher. His personal character is a subject of much controversy. The questions as to the teaching of T. are more important. His ability and success as a preacher led to his being intrusted with the charge of preaching an indulgence, first on behalf of the Teutonic Knights, and afterwards, in 1516, on the far more momentous occasion of the celebrated indulgence published in favor of contributors to the fund for building the church of St. Peter's at Rome. In the discharge of this commission, it cannot be doubted that T. went to extremes which it is impossible to justify; but the worst charges, and especially that of preaching the efficacy of indulgences without repentance, and of offering anticipatory pardons for future sin, are strongly denied by Roman Catholic writers as being contradicted not only by contemporary authorities, but also by the very instructions contained in his official commission.

Much of the obloquy which he drew upon his cause was produced by the pomp and apparent luxury in which he traveled about upon his mission. It was in opposition to the preaching of T. that Martin Luther published his celebrated theses, on the 31st October 1517. T. replied first by publicly burning these obnoxious propositions; but he afterwards published a series of counter-theses (which were burned in retaliation by the students of the university of Wittenberg); and in May 1518, a detailed reply to Luther's celebrated Sermon on Indulgences. On the arrival of the papal delegate Miltitz, T. addressed to him a letter in reply to the charges of his adversaries; but notwithstanding this defence of his conduct, he was summoned to appear before Miltitz in Leipzig in the January of the following year, and underwent a severe rebuke for the excesses in language, and the improprieties in proceeding, which had brought so much scandal upon the church. Miltitz threatened him, moreover, with the severest animadversions on the part of the pope. He was required in consequence to withdraw to his convent at Leipzig, where he died in the August of the same year, 1519, according to some of the plague, but according to another account, of the chagrin and mortification resulting from the judgment of the papal representative. —See on the one side, Hechlein, *Vita Tezelii;* Hoffman, *Lebensbeschreibung Tetzel's* (1844); and on the other Gröne, *T. und Luther* (1853). See also Kayser, *Geschichtsquellen über T.*) 1877.

TEUTOBURGER WALD (Lat. *Teutobergiensis Saltus*). See HERMANN.

TEUTO'NIC, a term applied to a group of nations, as well as of languages, forming an important division or stem of the Aryan (q. v.) family. The T. languages will be found enumerated and classified in the table at the end of the article PHILOLOGY. The T. stock of nations, as they exist at the present day, is divided into two principal branches: (1) The Scandinavian, embracing Danes, Swedes, Norwegians, Icelanders; and (2) the Germanic,

which includes, besides the German-speaking inhabitants of Germany proper (see GERMANY) and Switzerland (q. v.), also the population of the Netherlands (the Dutch), the Flemings of Belgium, and the descendants of the Anglo-Saxons in Great Britain, together with their offspring in North America, Australia, and other British colonies. It is necessary in this case, as in all similar cases, to guard against making language the sole test of race. In many parts of Germany where German now prevails, Slavic dialects were spoken down to recent times, and in some places are not yet quite extinct. And in Great Britain, it is unreasonable to suppose that the Anglo-Saxon invaders exterminated the native Celtic population, or even drove more than a tithe of them into the Highlands. The mass undoubtedly remained as subject serfs, learned the language and customs of their masters, and gradually amalgamated with them; so that, in point of blood, the English are perhaps as much Celtic as Teutonic.

Of the various tribes and nations spoken of as inhabiting Northern Europe in ancient times, it is often difficult to determine which were really of Germanic race, and which Celtic or Slavic; the classic writers having no skill in detecting the affinities of language, had only confused notions of ethnology. Of undoubted German nations who took part in the destruction of the Roman Empire, the most prominent were the Goths (q. v.), Lombards (q. v.), Vandals (q. v.), and Franks (q. v.). The term Teutonic is derived from *Teutones*, the name of a nation or tribe first mentioned by Pytheas, who wrote about 320 B.C., as then inhabiting a part of the Cimbric Chersonesus, or Jutland. For the next 200 years there is no further mention of the Teutones, that is, not until 113 B.C., when they appear in history as ravaging Gaul, and in conjunction with the Cimbri and Ambrones, threatening the very existence of the Roman republic. The Cimbri having gone into Spain, the Teutones and Ambrones were at length defeated by C. Marius in a great battle at Aquæ Sextiæ, or Aix, in Gaul, 102 B.C., in which from 100,000 to 200,000 of the invading army were slain, and many thousands made prisoners. A similar victory was gained by Marius in the following year over the Cimbri in the plans of Lombardy. It is disputed among ethnologists and historians whether the Cimbri so defeated were of the Celtic or of the Germanic race, and doubts have even been thrown on the claim of the Teutones to be considered Germans, although the best German scholars hold the claim to be established. Be that as it may, Roman writers, after the time of Cæsar and Tacitus, began to use the adjective Teutonicus as equivalent to Germanicus; and this practice was adopted in the middle ages by Germans writing in Latin. The native term was *theodisk*, from Goth. *thiud*, people; and it is from this word, and not from Teutonic, that the modern *Deutsch* is derived. See GERMANY.

TEUTONIC KNIGHTS, one of the more celebrated of the military and religious orders to which the Crusades gave birth. The sufferings of the Christian soldiers at the siege of Acre excited the sympathy of certain merchants of Bremen and Lübeck, who rendered such important services by the erection of hospitals and otherwise, that Duke Frederick of Swabia, with the sanction of Pope Clement III. and the Emperor Henry VI., enrolled them in an order of knighthood, as the Teutonic Knights of St. Mary of Jerusalem. Only Germans of noble birth were made admissible to the order, the original founders having probably been ennobled before being enrolled. The members were at first all laymen, but priests were soon admitted as chaplains; and there was also added about 1221, a class of half-brothers similar to the serving-brothers of the Templars and Hospitallers. The habit of the order was a white mantle with a black cross; and the knights took vows of poverty and chastity, which in later times were not very strictly interpreted. Their first seat was Acre. On the overthrow of the kingdom of Jerusalem, the grand-master removed to Venice, and from thence in 1309 to Marienburg, on the banks of the Vistula. In 1237, this order became united with the Brethren of the Sword in Livonia. In the course of the 13th c., the Teutonic Knights were, with the sanction of the pope, engaged in a bloody war to enforce Christianity on the heathen nations inhabiting the southern shores of the Baltic, which resulted in the acquisition by the order of Prussia, Livonia, Courland, and other adjoining territories. Warriors from all parts of Europe in that and the following century joined their standard, including Henry IV. of England, accompanied by 300 attendant knights and men-at-arms. The conquests of the order raised it to the rank of a sovereign power, with a territory extending from the Oder to the Baltic, and embracing a population of between two and three millions, the grand-master having his seat at Marienburg in Prussia.

The decline of the order began in the 15th c., and its fall was brought about partly by internal dissensions, and partly by the attacks of neighboring states. Sigismund of Poland wrested West Prussia from the knights; and Albert of Brandenburg, who was chosen grand master in hopes of his aiding the order against Poland, ended an unsuccessful war with Sigismund by an arrangement, according to which the territories of the order in East Prussia were formed into a duchy, to be held by Albert and his successors. Mergentheim in Swabia then became the seat of the grand master, who was recognized as a spiritual prince of the empire. At the peace of Presburg in 1805, the Emperor of Austria obtained the rights and revenues of the grand master; but in 1809 the order was abolished by Napoleon, its lands passing to the sovereigns in whose dominions they lay. The Teutonic order, however, still continues to preserve a titular existence in Austria.

TEW'KESBURY, an ancient market-town and parliamentary and municipal borough of Gloucestershire, in the vale of Evesham, on the Avon, and near its confluence with the Severn, 10 miles north-east of Gloucester. The parish church, an ancient and noble edifice in Norman, is the most noteworthy architectural feature. Hosiery, shoes, nails, leather, and malt are manufactured, and there is an extensive carrying-trade, of which T. is the center, on the Avon and Severn; pop. (1881) 5100. T., a very ancient town, appears to be of Saxon origin. Within half mile of it was fought (May 14, 1471) the famous battle of T., in which the Yorkists under Edward IV. and Richard III. inflicted a signal defeat on the Lancastrians.

TEXA'S, one of the south-western of the U. S. of America, is bounded on the S. W. by Mexico, and on the E. by Arkansas and Louisiana. Area (smaller than Alaska, but much greater than the German Empire or even Austria), 265,780 sq. m. Pop. (1860) 601,039; (1870) 818,579; (1880) 1,591,749 (of whom 253,500 were colored. Among the chief towns are Austin, the capital; Galveston, the principal seaport; San Antonio, Houston, Brownsville, and Jefferson. Nearly the whole Gulf coast is lined with bays, generally long and narrow, with shallow inlets—that of Galveston being 12 feet. The chief rivers are the Red River, which separates Texas from the Indian territory; the Sabine, Trinity, Colorado, and Rio Grande. These rivers, mostly navigable from 300 to 400 miles, run south-east, nearly parallel to each other, and empty into the Gulf of Mexico. The country on the coast of the gulf is level, with a gradual ascent, the middle region undulating with rolling prairies; the west is a high table-land, and the salt plains and staked plains (*el llano estacado*) on the borders of Arizona, are deserts 3000 to 4000 feet above the sea, without trees and in the summer without grass. There are a few small mountains in the west—spurs of the Rocky Mountains. The river-bottoms are well timbered. In Eastern T., wooded lands, called cross-timbers, alternate with prairies, and the country has a park-like and delightful aspect. The coast-region is formed of alluvial beds of sand or gravel; the middle, of outcrops of tertiary formations. In some places, petroleum is found on the surface of acid springs, and the earth is so charged with bitumen as to be used for fuel.
